THE PENNY CYCLOPÆDIA

OF

THE SOCIETY FOR THE DIFFUSION OF USEFUL KNOWLEDGE.

STEARIC ACID. This substance is procured from stearin [STEARIN], which is a compound of stearic acid and a peculiar sweet substance called glycerin, which is treated of under the head of SOAP.

When stearin is saponified by potash, stearate of potash is procured; and when warm dilute hydrochloric acid is added to the solution, the stearate is decomposed, chloride of potassium remains in solution, and the stearic acid is precipitated.

The properties of this acid are, that it has the form of brilliant white scaly crystals; it is inodorous, tasteless, insoluble in water, soluble in its own weight of æther and in hot alcohol, and the solution reddens litmus-paper; but its acid action is feeble, for it expels carbonic acid from the alkaline carbonates only at a boiling heat. It melts at about 158° Fahrenheit and on cooling it forms a crystalline mass: it is volatile, and may be distilled unaltered in close vessels. In the air it burns like wax. Its composition is somewhat differently stated by authors, but no one statement differs much from—

68 equivalents of carbon	.	408	79·4
66 equivalents of hydrogen	.	66	12·8
5 equivalents of oxygen	.	40	7·8
Equivalent		514	100·

In the state of crystals it contains two equivalents of water = 18, or nearly 3·4 per cent. It forms compounds with the alkalis, earths, and metallic oxides, which are called *stearates*.

Stearate of Ammonia.—Stearic acid absorbs ammoniacal gas; the resulting compound is white, inodorous, and has an alkaline taste. It is dissolved by boiling water, and the solution, on cooling, deposits pearly crystals of stearate of ammonia.

Di-stearate of Potash is formed by boiling equal weights of the acid and alkali dissolved in five times their weight of water. It forms a white granular compound, which is opaque, and may be purified by solution in boiling alcohol; as the solution cools, the salt separates in white brilliant scales. This compound may also be procured by treating potash soap with alcohol.

It is composed of—

One equivalent of stearic acid	.	514
Two equivalents of potash	.	96
Equivalent		610

Stearate of Potash is obtained by dissolving one part of potash soap made with suet and caustic potash, in six of hot water, and then adding about ten times their weight of cold water to the solution; the precipitate which results contains the stearate of potash mixed with margarate of the same base; from the latter it is separated by repeated treatment with alcohol, and is then obtained in soft silvery crystalline scales.

It is composed of—

One equivalent of stearic acid	.	514
One equivalent of potash	.	48
Equivalent		562

Di-stearate of Soda and stearate of soda may be obtained by processes similar to those described for the stearates of potash; they are less soluble than the salts of potash, and enter into the composition of hard soaps.

Stearate of Lime, Stearate of Barytes, and *Stearate of Lead,* are all white insoluble powders, and are not applied to any useful purpose.

Stearic Acid, besides its use in the manufacture of soap, is now very largely employed in the making of candles.

STEARIN (from στέαρ, *fat*) is the harder portion of animal fats; olein, or elain, being the softer one. To obtain stearin in a pure state, mutton-suet is to be melted with ten times its weight of æther in a water bath; as the solution cools, crystals of stearin are deposited, which, after washing with cold æther, are to be strongly pressed.

The properties of stearin are, that it has a pearly lustre, is soft to the touch, but not greasy; it melts at about 140° to 145° Fahrenheit; and, on cooling, solidifies into a mass, like wax, which is not crystalline in its texture, and is reducible to powder. Stearin is insoluble in water, but is dissolved both by hot alcohol and æther, from which it almost entirely separates on cooling; it possesses weak acid properties, and may be combined with potash; it is the chief and most important ingredient of the harder kinds of fat, and the harder they are the more they contain.

Stearin is separable into two different principles, namely stearic acid and glycerin, as has already been noticed in the preceding article; it appears to be a bi-stearate of glycerin, consisting of—

Two equivalents of stearic acid	.	.	1028
One equivalent of glycerin	.	.	83
Two equivalents of water	.	.	18
Equivalent			1129

The composition of stearic acid has already been given: glycerin is composed of, probably—

Six equivalents of carbon	.	.	36
Seven equivalents of hydrogen	.		7
Five equivalents of oxygen	.	.	40
Equivalent			83

STEARON is obtained by the partial decomposition of stearic acid; when distilled with lime, carbonic acid is formed, and the stearon produced at the same time is volatilized, and condenses in the state of a volatile liquid: it appears to consist of—

Sixty-six equivalents of carbon	.	396
Sixty-six equivalents of hydrogen	.	66
One equivalent of oxygen	.	8
Equivalent		470

So that it seems to be stearic acid deprived of two equivalents of carbonic acid.

STEAROPTEN. Volatile oils, as obtained by distillation from plants, appear, like expressed oils, to consist of two substances; one solid, which has received the name of *stearopten*, and the other liquid, called *elaopten*: the former generally crystallizes when the oil has been long kept.

Camphor is the most remarkable substance of the class of stearoptens. It is obtained by distillation with water, and in the plant is mixed with camphor oil, from the gradual oxidation of which it appears to be produced.

STEATITE, *Soapstone, Speckstein, Talc-Steatite.* This mineral, which is principally a hydrated silicate of magnesia, is met with massive in amorphous masses, which sometimes contain crystals of this substance of the form of quartz and calcareous spar, and which are probably pseudomorphous. Structure compact. Fracture uneven, splintery. Soft, and has a greasy feel. Colour yellowish, greenish, and greyish-white. Streak shining. Dull. Translucent on the edges. Specific gravity 2·604 to 2·632.

Before the blowpipe it is infusible either alone or with additions. It occurs plentifully in Baireuth, Saxony; in Cornwall, in Scotland, and many other parts of the world.

According to Klaproth it consists of—

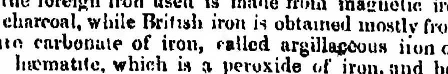
	Baireuth.	Cornwall.
Silica	59·50	45·00
Magnesia	30·50	24·75
Alumina	0·00	9·25
Oxide of iron	2·50	1·00
Water	5·50	18·00
	98·	98·

STEEL. Iron possesses many qualities which render it applicable to innumerable purposes in the arts; but there are some uses for which it is not sufficiently hard, and this defect is supplied by converting it into steel.

At Eisenärzt in Styria the manufacture of steel has been carried on ever since the eighth century, and yet the exact nature of the operation is perhaps even now imperfectly understood. It is generally admitted that steel is an intimate compound of iron and charcoal, for soft iron contains a considerable portion of charcoal, and it is by no means clear that the quantity is increased in the process of steel-making, and therefore we must conclude that some more intimate union is effected between them when iron is converted into steel. Whatever the theory may be, we shall now describe the mode in which the operation is conducted in this country, and principally at Sheffield.

In the first place it is to be observed that hitherto Swedish and Russian bar-iron have been exclusively employed in the manufacture of the best steel; the preference given to this iron is decided, though from what cause it arises has not been satisfactorily made out.* We may however remark that the foreign iron used is made from magnetic iron ore with charcoal, while British iron is obtained mostly from the impure carbonate of iron, called argillaceous iron ore, or from hæmatite, which is a peroxide of iron, and both of these are reduced by employing coal or coke prepared from it.

Bar-Steel is made, with few exceptions, from the Swedish and Russian iron, the bars of which are marked *hoop l* (1), *gl* (2), and *double bullet* (3); these, which are the best kinds, fetch from 31*l.* to 35*l.* per ton. Iron of lower quality is also used, such as (4), which is a Russian iron, and *c and crown* (5), *d and crown* (6), which are Swedish irons: these cost the importer about 20*l.* per ton; whilst there is a medium quality at about 25*l.* per ton, viz. *w and crowns* (7), *b and*



1 2 3 4 5 6 7 8

crown (8): these also are Swedish. These steel irons are imported almost exclusively by English merchants residing in Hull; the limited quantity of the fine iron allowed to be produced from the mines of Danemora in Sweden accounts in some degree for the high price at which they are sold. The quantity of iron, of the various qualities stated, which is imported into this country for the manufacture of steel is estimated at 12,000 to 15,000 tons, of which at least 9000 come from Sweden.

The usual operation in large steel-works is first to cut the bar-iron into certain lengths, leaving room in the vessels for the expansion of the iron, which amounts to $\frac{1}{16}$. The closed vessels in which the bars are heated are usually twelve feet in length, and divided into two pots or troughs, on the bottom of which the workman strews charcoal to the thickness of about an inch, and upon this he places on their flat side a layer of bars; then about three-fourths of an inch more of charcoal is added, and upon this he places another layer of bars, and so on till the troughs are filled; these are then covered with a ferruginous earth coming from the grinding-stones, called wheelswarf, to the thickness of about eight inches. All the apertures of the furnace are then closed with loose bricks and plastered over with fire clay. The fire is then lighted, and in four days and nights the furnace is at its full heat, at which it is kept for several days, according to the degree of hardness required. In order to be able to test the progress of the carbonization, a hole is left in one of the pots near the centre, and three or four bars are placed in the furnace in such a manner that the ends come through this opening, and after the sixth day one is pulled out. If the iron be then not sufficiently carbonized, the heating is continued from two to four days longer: a bar is drawn every two days, and when the iron is completely converted, the fire is heaped up with small-coal, and the furnace is left to burn out, and it requires from this period fourteen days' time to cool sufficiently to allow a person to go in and discharge the steel.

It is of the greatest importance that the pots or troughs be kept completely air-tight: the smallest crack will open when the furnace is hot, and admit the air: this of course frustrates the object of the operation, and any steel which has thus suffered is placed aside to be reconverted. It is of the greatest importance to give the iron the exact quantity of carbon required and no more.

1st. *For coach-springs.*—The iron must *not* be converted to the centre.

2nd. *For common cutlery, single and sheer steel*, and for purposes where steel has to be welded to itself or to iron, the conversion should be low, and gradually disseminated throughout the whole thickness of the bar.

3rd. *For double sheer steel*—the conversion should be somewhat harder than the preceding.

4th. *For files* and all instruments where resistance or fine cutting-edges are required, the conversion should be hard, and the iron fully carbonized throughout the bar, and the fracture should present small facets.

No definite rules can be laid down, nor can any distinct instructions be given to enable the uninitiated to judge of the temper or degree of hardness of a bar of steel; but by habit workmen soon acquire the means of distinguishing between the different degrees of hardness of two pieces of steel. This knowledge of the degree of temper is of great importance to the steel-maker, for though he is enabled to adapt the temper (hardness) of the steel to the wants of the manufacturer, a file, made from soft steel which would be valuable for welding purposes, would be useless in the arts, and a coach-spring made from steel hard enough to make a file could not be applied to its intended purpose.

A converting furnace contains generally fifteen tons of iron; and there are some large enough to hold eighteen to twenty tons. The bar-steel, when discharged from the furnace, is partially covered with small raised portions of the metal; and from the resemblance of these to blisters, the steel is called *blistered steel*. It has been supposed that these blisters arise from the expansion of carbonic oxide gas, formed and confined during the process of cementation; this however is not the case, for they evidently arise from the unsoundness of the iron, which is not throughout perfectly welded.

It has been found by the experiment of placing a bar of Swedish and one of Staffordshire bar-iron in the same furnace, that the former was much blistered, while the latter had scarcely any blisters larger than a pea. It must however be admitted that the cause of the blistering in one case, and its slight production in the other, are circumstances difficult of explanation.

At one time it was common for the steel-maker to receive orders for steel *well blistered*. This arose from a mistaken idea regarding the perfection of the steel, it being supposed that the more it was blistered, the more it was carbonized, and

* A patent has lately been obtained by Mr. Charles Sanderson for making iron fit for conversion into steel; from some instruments made from the steel so produced, now in the possession of the writer of this article, he is inclined to think favourably of the process.

consequently that its quality was indicated thereby; now however manufacturers are better informed, and steel so blistered is complained of.

Bar-steel as it comes from the converting furnace is used for various purposes without refining; those parts which are free from flaws and blisters are broken out and hammered or rolled to the sizes required by the manufacturer for files, edge-tools, table knives and forks, and coach-springs, and a great variety of common agricultural implements. It is also manufactured into what is called *single and double sheer steel;* for this purpose the converted bar is selected of equal degree of hardness, and broken into pieces of about two feet in length; these are taken to the forge, heated to a full cherry red, and hammered into bars two inches by three-quarters of an inch in thickness; six of these pieces are put together and kept firmly so by a hoop, which is fixed at the end of a handle, thus—

they are then placed in a hollow fire urged by a soft blast, and heated gradually up to a full welding heat, during which the workman covers the surface with clay beaten very fine; this runs over the surface, and to some extent prevents oxidation. When fully heated, they are placed under the hammer, carefully welded together and drawn into a bar of about two inches square at the same heat; the other end is then put into the fire and welded in the same way; this is termed *single* sheer steel. It is made *double* by nicking the bar in the middle and doubling it together, giving a second welding heat and drawing it out as before to a bar of about two inches square; it is then *hammered, tilted,* or *rolled* to the size required; by this process *bar steel* becomes more homogeneous, of a finer texture, and any instrument made of it will receive and retain a finer edge; the steel is also rendered much tougher, which is supposed to arise from the abstraction of a small portion of carbon, and the mechanical elongation of the fibre by these doublings, &c.

Manufacture of Cast Steel.—The fabrication of *cast steel* is comparatively a recent invention. It was first made by Mr. Huntsman, at Attercliff, near Sheffield, in 1770, since which time the manufacture of it has very much increased, and it is daily superseding the use of bar or shear steel, on account of the equality of its temper, and the superior quality as well as beauty of the articles which are made of it. The process adopted is that of taking bar steel converted to a certain degree of hardness and breaking it into pieces of about a pound each; a crucible charged with these is placed in the melting-furnace, similar to that used by brass founders. The cellar is usually arched, and the stacks are about 40 feet high; the furnaces are 20 inches long by 16 inches wide, and 3 feet deep. The most intense heat is kept up for two hours and a half or three hours, coke being used as fuel. When the furnace requires feeding, the workman takes the opportunity of lifting the lid of each crucible and judging how long the charge of each will be before it is completely melted: all the crucibles are usually ready about the same time; they are taken out of the furnace, and the liquid steel is poured into ingots of the shape and size required: the crucibles are immediately returned into the furnace; and when the contents of all have been poured into the moulds, the crucibles are again charged: they are used three times, and then rejected as useless. The ingots are taken to the forge-tilt or rolling-mill, and hammered into bars or rolled into sheets, as may be required. The celebrated *wootz*, or Indian steel, is cast-steel; but it is frequently so imperfect as to resemble cast-iron rather than cast-steel. It is however made of iron obtained, as the Swedish is, from the magnetic ore. Wootz is made by the natives from malleable iron, packed in small bits with wood in crucibles, which are then covered with some green leaves and clay: about two dozen of these crucibles are packed in one furnace; they are covered with fuel, and a blast given for about two hours and a half, which terminates the operation. When the crucibles are cold, they are broken, and small cakes of steel are obtained in the form in which it comes to England.

Having stated the mode in which steel is prepared, we shall now give an account of its properties and composition, and a concise view of the theories of its formation.

The properties of steel are, that it is of a lighter grey colour than iron, and which is so characteristic as to be described as a *steel-grey:* it is susceptible of receiving a very high polish, and this is greater as the grain is finer. The density of steel before hammering or hardening varies from 7·73 to 7·81. Dr. Thomson found the density of good blistered steel to be 7·823; by heating it to redness and sudden immersion in cold water, the density was reduced to 7·747: a piece of soft cast-steel similarly treated was reduced in density from 7·8227 to 7·7532. It follows therefore that when steel is hardened its volume is increased. When steel is heated to redness and slowly cooled, it is scarcely harder than iron; but by very rapid cooling it becomes hard, and so brittle as to be readily broken. The fracture of steel is usually fine grained; in ductility and malleability it is much inferior to iron, but exceeds it greatly in elasticity and sonorousness. It may be subjected to a full red heat, or 2786 Fahr., without melting, and is therefore less fusible than cast-iron, but much more so than wrought-iron. Pieces of steel which have not been cast may be readily welded together or with iron; but after casting the operation is more difficult. Steel does not acquire magnetic polarity so readily as iron, but retains it much longer; by exposure however to a moderate degree of heat this power is lost.

In order to give to steel the different degrees of hardness required for the various purposes to which it is applied, it is subjected to the process of what is called *tempering*. It has been mentioned that steel is hardened by heating and sudden cooling; and it is found that the higher the temperature to which it is raised, and the more sudden the cooling, the greater is the hardness: thus when immersed in mercury the hardness is greatest, on account of the good conducting power of the metal, and its consequent ready abstraction of heat. After this comes acidulated water, salt water, common water, and lastly oily or fatty bodies. It is found that, according to the degree to which steel is tempered, it assumes various colours, and formerly these colours served as guides to the workman; now however a thermometer, with a bath of mercury or of oil, is employed, and the operation is performed with a much greater degree of certainty.

Into this bath the articles to be tempered are put, with the bulb of the thermometer graduated up to the boiling-point of mercury. The annexed are the tempering heats, colours, and uses of steel of different degrees of hardness:—

430° Fah.,	very faint yellow; for lancets.
450° ,,	pale straw; razors and surgeons' instruments.
470° ,,	full yellow; penknives.
490° ,,	brown; scissors and chissels for cutting cold iron.
510° ,,	brown with purple spots; axes and plane-irons.
530° ,,	purple; table-knives and large shears.
550° ,,	bright blue; swords, watch-springs, truss-springs, and bell-springs.
560° ,,	full blue; small fine saws, daggers, &c.
600° ,,	full blue, verging on black; this is the softest of all the gradations, and the steel is fit only for hand and pit saws.

The degree at which the respective colours and corresponding hardness are produced being thus known, the workman has only to heat the bath and its contents up to the required point.

The degree of hardness attainable by steel depends upon the temperature to which it is raised, and the coldness or conducting power of the liquid into which it is immersed: so that, as observed by Mr. Brande, if very cold water cannot be procured, the steel-die or other article must be heated proportionably high;* a dull red heat into water at 34°, a cherry-red into water at 50°, an orange heat into water at 80°, a dull white heat into water at 100°, produce nearly the same effects: a red heat and water at 45° is the most desirable for the hardening; and although by subsequent tempering the die may, if necessary, be *brought down* or softened, it is always safest to give it due hardness by the first operation. In some cases steel is sufficiently hardened before any change of colour is produced. Capt. Kater found that 212°, or the heat of boiling water, was the exact point at which the knife-edges attached to a pendulum were properly tempered. The colour produced on the surface of the steel is supposed to be derived from slight oxidizement; and it is stated in corroboration of this opinion, that when steel is heated and suffered to cool under mercury or oil, none of the colours appear; nor do they when it is heated in hydrogen or azotic gases: the cause however of the

different degrees of hardness produced at the same time with the changes of colour has not been hitherto satisfactorily explained.

Case-hardening is the operation by which articles made of malleable iron or cast-iron are superficially converted into steel by heating them with charcoal in a crucible.

With respect to the composition of steel and the nature of the admixture requisite to constitute it, differences of opinion have long existed, and the question even now is considered by some as hardly decided, whether carbon is indispensably necessary to its formation, and whether certain substances or metals, especially silicon, may not give rise to it; and it is generally admitted that phosphorus is always present. Berzelius mentions iron containing manganese as particularly eligible, and yet the analyses which we shall presently state show that this metal is not present in steel in most cases; but we have understood that it is so in the steel made in Germany from spathose iron-ore, or carbonate of iron.

An experiment performed and described by Mr. Pepys in the 'Phil. Trans.' for 1815, seems not only to prove the necessity of carbon, but also that the diamond is capable of producing the same effect. In order to get rid of the objection that the carbonaceous matter of a common fire might supply carbon when iron and diamond were heated by means of it, he placed diamond-powder in a piece of pure soft iron wire; and having properly secured it, he heated it by means of voltaic electricity: after a few minutes' heating, the diamond had disappeared, and the interior surface of the iron was converted into perfect blistered steel, which, being heated to redness and plunged into cold water, became so hard as to resist the file and scratch glass.

Some years since also a method was discovered by Mackintosh of converting iron into steel by means of the carbon of carburetted hydrogen gas.

The following are the results of four analyses of the cementation steel of Remmelsdorf, department of the Moselle, by Vauquelin:—

Iron	98·72	98·38	98·27	97·74
Carbon	0·79	0·12	0·79	0·63
Silicon	0·15	0·82	0·15	0·11
Phosphorus	0·34	00·68	0·79	1·52
	100·	100·	100·	100·

It appears from the following analyses of cast-steel by Gay Lussac that during fusion the steel loses much silicon and a little carbon: the samples analyzed were (1) English, first quality; (2), French, first quality; (3), French, second quality; (4), Isère.

	(1).	(2).	(3).	(4).
Iron	99·32	99·24	98·87	99·27
Carbon	0·62	0·65	0·94	0·65
Silicon	0·03	0·04	0·08	0·00
Phosphorus	0·03	0·07	0·11	0·08
	100·	100·	100·	100·

In the opinion of Mr. Brande, the quantity of carbon in the above-analyses is somewhat underrated; and he has found that when the carbon has fallen short of one per cent, the steel was deficient in hardness; and when it has exceeded this proportion, the dies have split or not stood their work. He states, at the same time, that minute quantities of other bodies appear to influence the quality of steel; and that unless it contain phosphorus it cannot be depended on for the manufacture of dies in coining.

Dr. Thomson examined some cast-steel furnished him by Mr. Buttray, a steel-maker near Glasgow: the general result of his trials gave him—

Iron	99
Carbon with some silicon . .	1
	100

and this composition, he observes, approaches 20 atoms of of iron + 1 atom of carbon, and this he thinks likely to be the constitution of cast-steel, an opinion corroborated by the fact above stated by Mr. Brande. Mr. Faraday and Mr. Stodart published in the 'Phil. Trans.' for 1822 a valuable series of experiments on alloys of steel, from which it appears that by combining steel with other metals its quality is improved: for the details we refer to the memoir, merely stating that a very minute addition was found sufficient to produce a good effect: thus one 500th of silver gave an alloy harder than cast-steel; one 100th of nickel gave a very hard alloy, susceptible of a fine polish: alloys of rhodium and platinum were also formed; and these, with the alloys of iridium, osmium, and palladium, formed the most valuable compounds.

STEEL ENGRAVING. In the article ENGRAVING [vol. ix., p. 437] the history of the art of engraving upon metallic plates for the purpose of producing prints, or impressions, in ink, upon paper and other substances, as well as the chief points requiring notice in the practice of the art, has been treated of; and therefore it merely remains in this place to notice such matters as refer to the use of steel plates, which have of late been very extensively and advantageously substituted for those of copper.

As far as regards facility of execution, whether by etching or by cutting with the graver, probably no material could be found superior to copper, which is still preferred by many engravers, where the fine and free character of the work is more important than the durability of the plate; but the comparative softness of copper occasions it to wear so rapidly in the process of printing, that the beauty of the engraving is very soon impaired, and it is impossible to produce, from a single plate, a sufficient number of impressions for the illustration of books of large circulation. It should be borne in mind that, in copper-plate printing, the whole surface of the plate is covered with thick unctuous ink, which is rubbed into the lines with a ball of cloth applied with considerable force. The superfluous ink is then wiped off with a rag, and the surface of the plate is thoroughly cleaned by repeated wiping or rubbing with the palm of the hand, so as to leave the ink only in the lines or incisions in the plate, from which it is transferred to the paper by very powerful pressure in a rolling-press. This operation, being repeated with every impression, tends to the rapid deterioration of the plate, the surface of which is so worn by the constant friction, that the finest lines soon disappear, while the edges of the widest and deepest incisions become so rounded that they will not contain the proper quantity of ink. Hence it becomes necessary, where many impressions are required, to retouch and deepen the engraving after printing a few hundred copies; but even this measure, troublesome and expensive as it is, will not restore the engraving to its original beauty. The use of steel plates for diminishing this inconvenience, although not extensively resorted to until within the last twenty years, is a measure of which the possibility was conceived at an early period. It is believed that Albert Dürer, who also made experiments upon plates of tin, silver, &c., engraved a few steel plates; impressions of which, or of some of which, are preserved in the collection of the works of that artist in the British Museum. They appear to be executed chiefly, if not entirely, by the process of *etching*. Probably many other engravers may have tried engraving upon steel, but the difficulty of cutting it, on account of its hardness, and the want of a good menstruum for the purpose of etching, prevented the accomplishment of anything important in steel engraving until recently.

The introduction of the modern art of steel engraving appears to be attributable, in a considerable degree, to the excitement which existed rather more than twenty years since on the subject of the forgery of bank-notes. That subject was investigated in 1818 by a committee of the Society for the Encouragement of Arts, Manufactures, and Commerce, who received several proposals for rendering bank-notes more difficult of imitation; and the very interesting communications made to the committee were published by the Society in 1819, as a supplement to their 'Transactions.' The introduction of superior workmanship in the engraving of plates for bank-notes was one of the measures particularly recommended on this occasion; but, while it was shown that the employment of superior engravers, and the introduction of well-executed vignettes, had been found advantageous by country banks as a means of preventing forgery, it was a measure inapplicable to the small notes then circulated in immense numbers by the Bank of England, which were the notes most extensively forged. 'It is in evidence,' observe the committee, 'that the average number of copies taken from each copper plate does not much exceed six thousand;* hence, if the expense

* Mr. Warren stated that about seven thousand copies were taken by the Bank of England before the copper plates used by them required to be retouched; but other witnesses mentioned from five to six thousand as the number of impressions which each plate would afford. It is almost needless to observe that the great difference between the early and late impressions rendered it more difficult for an inexperienced person to detect a forgery than it would have been if no perceptible difference existed between the genuine notes.

of engraving were greatly enhanced, the profit arising from the issue of one-pound notes would entirely cease.' 'If,' it proceeds, 'the daily issue of small notes from the Bank of England amount to thirty thousand,—and, from the evidence produced, there is reason to believe that it exceeds rather than falls short of this number,*—there is a daily consumption of five plates, or fifteen hundred in the year; and there might perhaps be some difficulty in finding a sufficient number of superior artists to produce the required quantity of plates.' The substitution of steel for copper is then adverted to as a measure likely to obviate these difficulties, because, owing to its greater hardness, it was believed that a steel plate might be made to afford twenty, or perhaps thirty times the number of impressions that copper would do; so that, while perfect similarity might be insured in a much larger number of notes, a far greater expense might be advantageously incurred in the engraving of each plate. Mr. J. T. Barber Beaumont, in his communication to the committee, after alluding to the ultimate economy of the plan, notwithstanding the increased cost of the proposed steel plates with well-executed vignettes, as compared with the badly engraved copper-plates then used, which contained nothing worthy of the name of a work of art, observes:—'A further effect of this system in preventing forgeries would be found in all the notes of one kind for a long period of years being taken from one plate, whence a person having a genuine note might compare it with the minutiæ of another suspected to be forged; and as it would be impossible even for the artist himself who had engraven an original plate to follow, in a copy, the length, sweep, depth, and number of the strokes in his original, a detection would be easily made, even by those who knew nothing of the arts.' The conditions of this argument, although unattainable to the extent here intimated by the use of soft steel plates, might be perfectly accomplished by the transferring process hereafter described. Mr. Warren exhibited to the committee a specimen of engraving upon soft steel, which fully proved its practicability; and it was also explained by several witnesses that a block or plate of steel might be softened so as to render it easy to cut, and subsequently hardened to enable it the better to resist wear in printing. Something of this kind indeed had been practised in North America. American bank-notes were shown to the committee, containing ornamental borders, partly of machine-work, which were pronounced to be 'scarcely, if at all, imitable by the common process of engraving.' Mr. Clymer, a gentleman who had been engaged in the production of bank-notes in the United States, stated that these borders were engraved upon thick plates of soft steel, and proceeded to describe the process as follows:—'After the pattern has been completed, the plates are hardened. These plates are then employed to impress a reverse on rollers of very soft cast steel, by repeatedly passing the plate between the rollers. The rollers are then hardened, and from these the impression is transferred to plates of copper, on which the writing and vignette are afterwards engraved in the usual way.' The Report of the committee was accompanied by impressions from two steel plates, engraved by Mr. Williamson. They consist of engine-turned patterns; and, although not remarkably delicate, are very well executed.

The resumption of cash payments by the Bank of England, and the subsequent discontinuance of small notes, rendered the proposed improvements less imperatively necessary; yet steel plates have been, since the date of this Report, rapidly extending in use, both for bank-notes and other matters in which writing and ornamental machine-work form the principal feature, and for engravings of higher character. The principal improvements by which this very important change has been effected, are recorded in the published 'Transactions' of the Society of Arts; and that association has done much to encourage the progress of steel engraving. In noticing some of the chief improvements in question, a distinction will be made between the process of engraving on decarbonised plates which are intended for subsequent hardening, and that of engraving upon such plates of soft steel as are printed from without hardening.

The former of these is the process introduced into this country, in connection with the transferring operation above alluded to, by Messrs. Perkins and Fairman, from the United States. Their method of producing engraved steel plates was established in England soon after the date of the Society's Report. Mr. Charles Heath, the eminent English engraver, being associated with the American artists; and it is fully described in a communication from the three partners to the thirty-eighth volume of the 'Transactions' of the Society of Arts, whence it was transferred to several other works. The engraving is executed upon a plate or block of cast-steel, which, to prevent the risk of warping, is of considerable thickness. About five-eighths of an inch is stated to be the average thickness of the plates used by Mr. Perkins. The surfaces of this plate are decarbonised by placing it in a close cast-iron box, with a sufficient quantity of iron-filings to cover the plate to the thickness of at least half an inch, and exposing it, while thus enclosed, to a white heat, until the steel is decarbonised, or converted into very pure soft iron, to a depth equal to about three times the depth of the incisions to be made in executing the intended engraving. The box is then cooled very slowly, being covered up with fine cinders to prevent the access of air. In performing this process, it is said that the plates are least likely to warp when in a vertical position; and that it is advisable to decarbonise each side of the plate equally. On the plate thus softened the engraving is effected with facility; and, when it is completed, the hardness of the surface is restored by exposing the plate for some hours to a red heat, the surface being thickly covered with animal charcoal, formed of burnt leather or bones, and the whole being, as before, enclosed in a cast-iron box. The plate is afterwards cooled in water; but it is not allowed to remain in the water till quite cold, but taken out so soon as it is cooled to the tempering heat, which is ascertained by careful attention to the sound emitted. The plate should be taken out when at the heat required for tempering to a straw-colour, and afterwards lowered by holding it over a fire until tallow, smeared on its surface, is decomposed by the heat, so that smoke arises from it. It is then again put into water till the sound emitted is rather weaker than before. These operations are repeated until the plate has been three times lowered, or softened, over the fire, and three times partially hardened by cooling, after which it is finally cooled in water. It is then cleaned off, and again tempered over a fire to a brown or such other colour as may be needed. From this hardened plate the engraving is transferred to a softened steel roller, of small diameter, which is pressed against the plate with such force that its surface becomes embossed with a perfect transfer or impression of the engraved device. The roller, or cylinder, is then hardened in a similar manner to the original plate, and is afterwards made to transfer the devices from its surface to any required number of softened or decarbonised plates, which are then hardened for printing from. This beautiful process is not only applicable to transferring engravings from one plate to another; but, in cases where one ornament has to be repeated several times on one plate, the device may, by being once engraved, be impressed as often as necessary upon different parts of the same plate. The power of multiplication is, for all practical purposes, unlimited. An instance of its utility, which will be familiar to every one, is afforded by the adhesive stamps used as postage labels since the adoption of the penny postage: the device of the queen's head has been only once *engraved*, although, by the application of this process, it has already been multiplied about *six thousand* times, each impression or transfer upon steel being equal to the original engraving, and capable of yielding an immense number of prints or impressions on paper. The number of impressions yielded by each hardened steel plate depends much upon the character of the engraving, and in some degree upon the success of the recarbonising or case-hardening operations, but it may be stated generally to range between fifty and a hundred thousand. In some cases the latter number has been greatly exceeded; and, in the paper from which the above account of the art is chiefly derived, an instance is mentioned in which *five hundred thousand* copies were printed from a plate which was strongly engraved. During the twenty years in which this process, which was formerly termed *siderography*, has been practised in this country, several minor improvements have been effected; but we believe that the above account remains substantially correct. The perfection which has been attained is almost beyond conception; the finest writing, and the most minute and intricate patterns, being transferred from plate to plate with such precision that the keenest scrutiny cannot detect a

* 'Mr. Ramshaw stated, that he has heard from good authority, that the daily issue of Bank of England notes of all descriptions is about *sixty thousand*, in producing which about fifty-three presses are employed.' (*Minutes of Evidence*, p. 61 of *Report*.)

difference between the original and the transfer. Even the early specimens which accompany the paper above referred to, fully justify this remark. The plan has been much used for country bank-notes and similar purposes, and has been occasionally resorted to for engravings of pictorial character, for which however the kind of steel engraving yet to be noticed is most commonly employed.

The application of steel engraving to matters of fine art is, in a great measure, due to the late Mr. Charles Warren. In 1823 that gentleman made a communication upon the subject to the Society of Arts, who voted him their large gold medal for his improvements in the art; a prize which he did not live to receive. Owing to his death before the rewards of that year were bestowed, the Society were deprived of a full communication which was to have been made by him, and consequently the details published in the forty-first volume of their 'Transactions' are less perfect than might be desired. It is there stated that Warren had in his youth been engaged in engraving for calico-printers and gunsmiths, by which employment he was led to devote some attention to steel engraving. Mr. Gill, one of the chairmen of the committee of mechanics in the Society of Arts, and subsequently editor of the 'Technical Repository,' suggested to him the method practised at Birmingham in ornamenting snuffers and other articles of cast steel, by decarbonising the surface to render the execution of the pattern easy, and subsequently case-hardening the article; a process very similar to that described as forming part of the art of siderography. Serious difficulties impeded the application of this plan to plates suitable for engraving; because, if they were made thin, like ordinary copper plates, they were liable to warp in hardening; while if thick enough to avoid this danger, it was impossible to beat up the surface from the back in the usual way, when it was necessary to make any correction or erasure. When alterations were required in a thick plate, it was found necessary either to grind down the whole surface of the plate, thereby losing the whole of the work instead of merely the defective part, or to force up the surface in the faulty place by inserting a screw in a hole drilled at the back. These inconveniences led Warren to try the durability of steel plates when printed without hardening. It was ascertained that such plates would yield a sufficient number of impressions for ordinary purposes; while, by dispensing with the hardening process, they might be made thin enough to allow of beating up without inconvenience. Prints were exhibited to the Society from two soft steel plates engraved by Warren, containing very delicate work in landscape and figures, of which four and five thousand impressions had been taken respectively, and yet between one of the first and one of the last copies there was no perceptible difference. Some other of the specimens produced, portraits for the 'Evangelical Magazine,' had printed twenty-five thousand copies, and yet remained in good order; and in another case the engraver's proofs were not taken till twenty thousand copies had been printed.

Warren's original mode of decarbonising steel plates was similar to that adopted by Perkins, excepting that the box was filled with a mixture of iron turnings and pounded oyster-shells, instead of simply iron filings, and that several plates were laid in the same box, alternating with layers of the decarbonising mixture. Mr. Hughes, a copper-plate maker, improved upon this process by substituting a box or case of refractory clay for the cast-iron box; by which means he was enabled to apply a degree of heat that would have melted the iron, and thereby to soften the plates more completely. Each plate required two or more 'cementations' to soften it to the required degree; and Warren rectified any accidental warping by striking the plate with a hammer between these operations. Hughes found it better to perform this operation with a mallet, and to apply that with as little force as possible.

It is recommended that the surface of a steel plate should not be polished very highly, and that in applying etching ground to it, the plate should not be heated quite so much as is usual with copper. In either case the ground is apt to granulate or *honey-comb* upon the plate, by contraction in cooling. The ground should also be laid rather thicker than upon copper. Warren tried several different menstruums, but that which he most approved consisted of half an ounce of crystallized nitrate of copper, dissolved in a pint and a half of distilled water, with a few drops of nitric acid added to the solution. He recommended that it should be laid on the plate in a layer not exceeding one-sixth of an inch deep, to enable the operator to see the action distinctly; and that the plate should be constantly swept with a camel hair brush, to remove the precipitated copper, which, if left in the lines, would render them rugged. When this kind of menstruum is employed, it is necessary to lay on the Brunswick black or other varnish used for covering such parts as are sufficiently etched, or *bitten in*, very smoothly; because anything like a ridge retains the deposited copper, and where it remains the ground is liable to give way.

In 1824 the Society of Arts gave their large gold medal to Mr. Edmund Turrell for his improved menstruum for etching on steel, by which the inconvenience of sweeping away the copper was avoided. It consists of four parts *by measure*, of the strongest pyroligneous (acetic) acid, and one part of alcohol, or highly rectified spirits of wine. These should be mixed, and gently agitated for about half a minute, after which one part of pure nitric acid should be added. The rapidity of the process of etching may be increased or diminished by exceeding or reducing the proportion of nitric acid in the mixture. This menstruum should not be mixed long before it is wanted, as it deteriorates by keeping many hours. After etching, the plate should be washed with a mixture of one alcohol to four water. Turrell recommends that Egyptian asphaltum dissolved in essential oil of turpentine be used for stopping out, as the common Brunswick black of the shops is affected by alcohol. In 1826 the Society rewarded Mr. Humphrys for a menstruum for soft steel, consisting of a quarter of an ounce of corrosive sublimate and the like quantity of alum, both powdered, dissolved in half a pint of hot water, but cooled before it is applied to the plate. This menstruum should be kept constantly stirred with a camel-hair brush while acting; and, as it soon becomes turbid, it should, in etching fine work, be thrown away and renewed after acting a short time. This menstruum has received the sanction of several eminent engravers. Some engravers, we believe, use two different kinds of menstrua for etching on steel: one for biting-in the more delicate tints, and another for etching the parts that require considerable depth.

Allusion has been made to the difficulty experienced by the early steel engravers in consequence of the hardness of the metal, which rendered it very inconvenient to cut, and constantly broke the points of their tools. In Gill's 'Technical Repository,' vol. iii., p. 356, it is stated that Warren found the best gravers for the purpose to be those made by Mr. Stodart, of his alloy of cast-steel and rhodium. In the eighth volume of the same work, p. 296, Turrell recommends a process of cold hammer-hardening for gravers for steel plates.

In the application of steel engraving to matters of fine art, the accomplishment of mezzotinting upon steel plates is one of the most important points, as the wear of copper plates engraved in this manner is very rapid. The advantages of steel plates, and the peculiarities of the mezzotinting process as applied to them, are alluded to in a previous volume. [MEZZOTINTO, vol. xv., p. 169.] According to Gill (*Tech. Rep.*, vol. iii., p. 287), mezzotinto engraving was executed upon steel as early as 1820, by Messrs. Perkins, Fairman, and Heath. In 1822 Mr. Thomas Lupton was rewarded by the Society of Arts for an engraving in this manner on soft steel, and he then exhibited good impressions from a plate which had yielded fifteen hundred impressions; and in 1824, in the forty-second volume of the Society's 'Transactions,' an interesting paper was published upon the invention, progress, and advantages of engraving in mezzotinto upon steel, by Mr. Charles Turner. That artist states that the subject was suggested to him as early as 1812, and that, finding steel, as then prepared, too hard, he tried brass, but without success. In January, 1820, Say executed a mezzotint engraving on one of Perkins's plates, and before the date of Mr. Turner's communication, this new branch of art had been practised also by Ward, Reynolds, Lupton, &c. 'In engravings in mezzotinto on steel,' he observes, 'the tones are far better defined than those obtainable upon copper. From the superior density of the metal, the clearness of the lighter tints is carried to much greater perfection; and, from the same cause, the darks have also a decided preference, being distinguished by their superior richness.'

To preserve steel plates from injury by rust, it has been recommended to smear their surface with sheep's suet, rubbed on while the plate is warm. Some use virgin wax for the same purpose; heating the plate to such a degree

that a cake of wax, when gently rubbed over it, leaves a thin but perfect film upon it.

The cost of engraving upon steel is considerably greater than that of engraving upon copper:* yet, as steel plates afford so many more impressions than copper, they enable the publisher, by calculating his returns upon a large instead of a small number, to issue works of art at so low a price as may ensure their very wide circulation. This may be illustrated by referring to the series of maps published by the Society for the Diffusion of Useful Knowledge. The cost of production in this and in every similar case, may be divided into two parts: the cost of authorship, engraving, &c., which is a fixed sum, independent of the number of impressions required; and the cost of paper and printing, which is a fixed sum *for each impression*, whether the edition be large or small. The latter part of the cost forms therefore an unalterable sum for each copy; but the former must be incurred alike for twenty or two thousand copies, and may be met either by a large sum added to the price of each copy in a small edition, or by a small sum charged upon each copy in a large edition. Had the Society calculated upon a sale of only two thousand copies of their maps (which was the utmost number that experience would have entitled them to hope for), the estimate would have stood somewhat as follows:—

Expenses incurred for each plate, independent of the number of copies required—

Assumed cost of authorship . .	£21	0	0
Assumed cost of engraving (*on copper*)	21	0	0
	£45	0	0

Expenses dependent upon the number of copies printed—

Paper for two thousand copies . .	£5	0	0
Printing two thousand copies . .	8	0	0
	£13	0	0

Dividing these sums by two thousand, it will be seen that the cost of paper and printing for each copy is about 1·56*d.*, and the proportion of the cost of the plate chargeable upon each copy is 5·40*d.*, making the total expense of each copy 6·96*d.*, or very little under 7*d.* Allowing therefore the usual addition of one-third for the profits of the retailers, the price to the public could not have been less than 10½*d.* Supposing the number sold to be four thousand, the total cost per copy would have been reduced to 4·26*d.*, because the expense of the plate, being distributed over double the number of copies, would have been but 2·70*d.* for each. But this number of impressions would have worn out a copper plate, even supposing, which would be an extreme case, that so large a number could have been printed without too great a deterioration of the engraving. The Society however determined upon going to the greater expense of steel plates, which the engraver undertakes shall be capable of furnishing twenty thousand copies; and they calculated their returns upon a sale of eight thousand copies. The estimate of first cost therefore stands nearly as follows:—

Assumed cost of authorship . .	£21	0	0
Cost of engraving (*on steel*) at least .	35	0	0
	£56	0	0

but by dispersing this larger sum over a number of eight thousand copies, the proportion chargeable to each is reduced to 1·68*d.*, which, with 1·56*d.* for paper and printing, makes the total cost of each copy 3·24*d.*, or rather less than 3¼*d.* Thus the maps were profitably published, even with the addition of a wrapper, at 6*d.* each. The result has fully justified this measure, as, of some of the earlier numbers, upwards of twenty thousand copies have been sold, a number which the best engraved plates have yielded without perceptible injury. The sum mentioned as the cost of engraving is about the least which has been paid; but assuming it to be the cost, the proportion of first cost chargeable on each copy of the maps which have been most extensively circulated is only ·672*d.*, which, with the price of paper and printing, makes the cost per copy 2·232*d.*, or little more than 2¼*d.* If copper plates had been used, notwithstanding the smaller cost of engraving, it would probably have been impossible to reduce the cost per copy below 4½*d.*, or from that to 5*d.*; because, if twenty thousand impressions had been required, five plates must have been engraved, at an expense of at least 120*l.*, instead of one at the expense of 35*l.*

In the production of illustrated books, the advantages of steel engraving are strikingly observable, since, by acting upon the principle above stated, many works have been published of late years which could not have been produced with copper-plate engravings, because the number of impressions being so limited, the price of each copy must have been such as to preclude the possibility of a remunerative circulation. To take an instance, by no means the most recent, it may be mentioned that the beautifully illustrated edition of Rogers's 'Italy,' issued in 1830, was published profitably at the low rate of twenty-eight shillings, although seven thousand pounds had been expended in its production; so that, merely deducting one-fourth for the regular allowance to booksellers, at least seven thousand copies must have been sold to return the cost of production. The volume of poems by the same author, which was published soon afterwards, although issued at the same price, was still more expensive in its production. (*Printing Machine*, vol. i., p. 13.) In periodical publications of large circulation the use of copper plates was attended with great expense and inconvenience. The 'Evangelical Magazine,' for example, in order to supply portraits for an edition of more than twenty thousand copies, was compelled to use four distinct plates, each of which, in many cases, had to be repeatedly retouched by the engraver to make it yield the necessary number. In January, 1823, steel was first adopted for this work; and, one plate being sufficient, much more elaborate engravings were used. Of the portraits engraved on steel for this and another work of similar character, it is not unusual to take the full number now required, about sixteen thousand copies, without any repair being done to the plate.

The recently invented art of multiplying engraved copper-plates by voltaic electricity may possibly have some effect upon the future use of steel engraving; since it affords the means of obtaining an indefinite number of impressions without deteriorating the original plate. The inferior density of electrotype plates, which would, it is supposed, occasion their rapid wear, has been urged as an objection to their use for printing long numbers; but the writer has been assured that ten thousand impressions have been obtained from one electrotype plate, the engraving of which was strong and deep.

STEELE, SIR RICHARD, was born at Dublin in 1671. His father, who was private secretary to James, first duke of Ormond, sent his son to be educated at the Charterhouse in London; thence Steele was removed to Merton College, Oxford, and admitted a postmaster on that foundation in 1691. He afterwards was an ensign in the Guards, and in 1702 attracted the notice of the public as an author by the publication of 'The Funeral, or Grief à-la-Mode,' a comedy, successfully acted in that year. Two more comedies, 'The Tender Husband,' acted in 1703, and 'The Lying Lover,' 1704, followed this first attempt. In 1709 he commenced 'The Tatler,' the first, in our literature, of a series of periodical works in the form of short essays. He was soon after made one of the commissioners of the Stamp-office. In 1711 he began, in conjunction with Addison, 'The Spectator,' and in 1713 'The Guardian.' In this year he was dismissed from his situation in the Stamp-office, and was elected member for Stockbridge in Hampshire. In March of this year he was expelled the House for writing two pamphlets, 'The Englishman' and 'The Crisis,' on the succession to the crown of England, alleged to contain treasonable matter relative to the reigning family: he was supported on this occasion by Addison, and other distinguished members of parliament.

After the accession of George I., in 1715, Steele was made surveyor of the royal stables at Hampton Court, and was knighted on the presentation of an address. The same year he was chosen member for Boroughbridge in Yorkshire, and appointed one of the commissioners of forfeited estates in Scotland. He continued to write articles relative to the political events of the time, and in the latter years of his life appears to have suffered much from poverty, caused partly by a habit of speculating in new projects. He sustained a considerable loss—nearly 10,000*l.* by his own account (see his letter to the duke of Newcastle, *Epis. Corr.*, 469)—by the revocation, in 1719, of the patent by which he

* In the infancy of the art it was usual to charge engraving upon steel double the price demanded for the same work upon copper; and even now the comparative expense of engraving upon steel and copper is, we believe, in most cases, about as three to two.

was constituted governor of the royal company of comedians. In 1722 his comedy of 'The Conscious Lovers' was acted. Some time before his death he retired into Wales, to his seat at Llangunnor, near Caermarthen, where he died September 1, 1729. He had been twice married, first, to a lady of Barbadoes, secondly, to Elizabeth, the daughter of Jonathan Scurlock of Llangunnor, Esq., by whom he had a daughter, married in 1732 to the Hon. John Trevor, afterwards Baron Trevor of Bromham.

Steele has the merit of having originated a kind of periodical literature not before known in this country. Of the value of the series of works commencing with 'The Tatler,' of which, in conjunction with Addison, he was the author, it is needless here to speak. They are remarkable for a style combining with the ease of familiar conversation grammatical correctness and purity of language, for the invention and judgment shown in the choice, and the versatility in the treatment, of the subject, and, above all, for the refined and Horatian satire which, expressing itself in a tone of playful irony, and by means of allegory and representation of character never directly personal, formed the taste and reformed the manners of the generation by whom the perusal of these writings was regarded as a passing amusement.

There is a full biography of Steele in Chalmers's 'Biographical Dictionary.' Authority for the principal facts there stated may be found in his Epistolary Correspondence, published from the originals in the British Museum, and illustrated with literary anecdotes, by John Nichols, 2 vols., 1788; who also edited, in 1791, 'The Theatre, with the Anti-Theatre,' Steele's Case with the Lord Chamberlain, with other of his tracts; and in 1790, 'The Town Talk,' 'Fish Pool,' 'Plebeian,' 'Old Whig,' 'Spinster,' &c., 8vo. His plays were published in 12mo. by Tonson, 1755.

STEELYARD, in mechanics, a kind of balance or weighing-machine, consisting of a lever of unequal arms. The most common kind of steelyard, which is often called the Roman balance, is a lever of the first order, and is used by suspending the article to be weighed from the end of the shorter arm, and sliding a determinate weight along the longer arm, to a greater or less distance from the fulcrum, until the instrument remains in equilibrium in an horizontal position; the weight of the substance attached to the short arm of the lever being indicated by observing the position of the moveable balance-weight with respect to a graduated scale marked upon the long arm of the steelyard. In the common steelyard a hook or hooks are usually suspended from the short arm, to hold the article the weight of which is to be ascertained; but sometimes a scale-plate or dish suspended by chains is added. The moveable weight is commonly attached to a ring, the form of which enables it to rest in notches cut on the upper edge of the steelyard, corresponding with the graduations engraved on its side. A ring or hook is also attached to the fulcrum, so that the instrument may be conveniently hung upon a fixed support, or if small, held in the hand; and a vertical index or pointer, similar to that attached to the beam of common scales, is sometimes added. The fulcrum, and the axis from which the weight is suspended, should, when much nicety is required, be provided with knife edges or bearings resembling those used in other lever-balances. Many steelyards are supplied with a second fulcrum; the two being placed at different distances from the point to which the hook or scale is attached, and having their respective pointers and suspending-hooks on opposite sides of the lever, or rather, when held in the position for use, one above and the other below it, as shown in the cut of an antient Roman steelyard which is inserted at the end of this article. In using a steelyard of this kind, capable of weighing from one to sixty pounds, the fulcrum which is nearest to the middle is used if the article be under fifteen pounds; while, if it exceed that weight, the instrument must be inverted, and suspended from the fulcrum which divides the lever most unequally. Of course when this arrangement is adopted, the shackles, from which the article to be weighed and the moveable weight are suspended, must be so formed as to hang equally well in either position of the lever; and different graduated scales must be used for each. It scarcely need be observed that, while it is a peculiar character of this kind of balance that the weight used is much lighter than the article weighed, it is possible to use it for bodies of less weight, by placing the moveable weight nearer to the fulcrum than the fulcrum is to the axis from which the article hangs. The degrees of sensibility and stability must be regulated in the same way as in an ordinary equal-armed balance. [BALANCE, vol. iii., p. 307.]

Various modifications of the steelyard have been contrived for delicate scientific purposes, or for adapting it to the purpose of weighing very heavy bodies. The improvements made by C. Paul, of Geneva, about forty years since rendered this kind of balance capable of weighing with great nicety. They are fully detailed in the third volume of Tilloch's 'Philosophical Magazine,' in a paper translated from No. xlv. of the 'Journal des Mines;' and also in the second volume of Gregory's 'Mechanics,' under the title 'Steelyard.' M. Paul placed the points of suspension exactly in the same horizontal line as the divisions of the beam; and he balanced the steelyard in such a way that, when unloaded, the beam might remain perfectly horizontal, and the index or cock attached to it perfectly vertical. Hence it became easy to ascertain the accuracy of the steelyard by simply unloading it. Instead of obtaining the power of weighing substances of very different weights by the use of two fulcrums, as above described, he used two different weights, with the same fulcrum and graduated scale; one weight being a multiple of the other; so that, for instance, if the heavier indicated, when placed against the figure 10 on the graduated scale, a weight of ten *pounds*, the smaller, placed in the same position, would indicate ten *ounces*. By using the two weights together, the weight of a very heavy body might be ascertained with great nicety. A steelyard which Paul constructed was capable, it is stated, of indicating as little as *one ten-thousandth part* of the weight with which it was loaded. Another advantage attending the use of two weights of this kind consists in the facility which they afford for testing the accuracy of the balance by transposing the weights. Thus, with a correct steelyard, graduated for avoirdupois weight, the balance will be the same whether the larger or *pound* weight be placed at 1, or the smaller or *ounce* weight at 16. The general adoption of such a contrivance would obviate the principal objection to the use of the steelyard for the ordinary purposes of commerce, the facility which it affords for fraudulent deception. Tilloch gives a representation of one of M. Paul's steelyard balances, contrived for scientific purposes, for which it was proposed to use different sets of weights with the same engraved scale, to indicate the weight of the object under examination according to various systems of weights. In a steelyard contrived by Mr. Patten, of Rhode Island, United States, for purposes for which much delicacy is required, the weight is attached to a sliding-box, which traverses along the beam by means of a screw. The screw passes through the sliding-box, and is secured by bearings at its ends in a position parallel with the beam, and it is turned by a milled head. In a large balance on the principle of the steelyard, known as Payne's weighing-machine, the weight is attached to a long box or case, which slides along the beam, and is supplied with a thumb-screw, the point of which is made to press against the side of the beam in order to secure the slide at any required point. The large weight attached to this sliding-box indicates, by a scale marked on the beam, the larger amounts, as hundreds and quarters; and the smaller, as pounds and ounces, are shown by means of a small weight traversing a scale engraved upon the sliding-box.

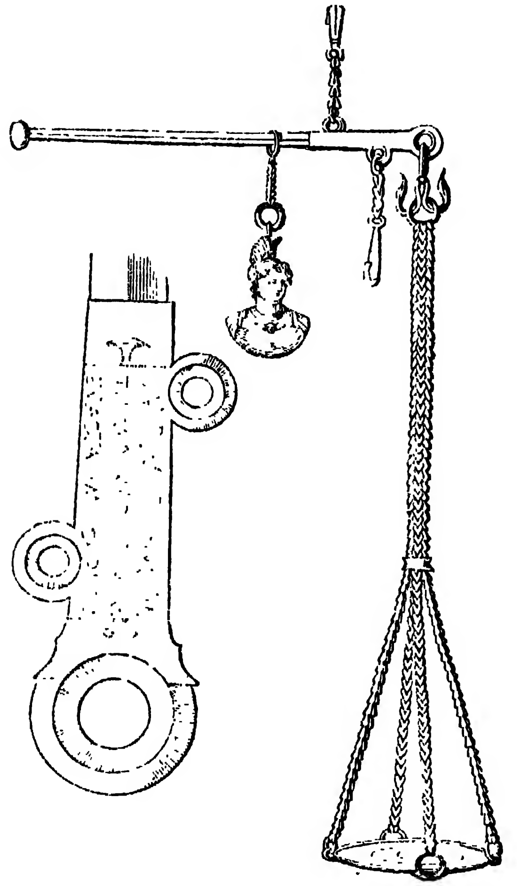
Several ingenious bent-lever balances have been contrived, some of which, from the circumstance of the levers being of unequal arms, resemble the steelyard in principle. These, and the steelyard weighing-machines for ascertaining the weight of loaded carriages, are noticed under WEIGHING-MACHINE.

The balance known as the Danish or Swedish steelyard differs from that above described in having the weight fixed at one extremity of the lever, while the fulcrum itself is moveable.

Though probably not so antient an invention as the equal-armed balance, the steelyard is an instrument of very early origin. Under the name of statera it was well known to the Romans, who often used a weight in the form of a bust. Vitruvius (book x., chap. 8) mentions the statera, and describes the principle on which it acts. Many Roman staterm of brass still exist, some of which are very like the steelyards of the present day. One of these, with a double fulcrum, weight, and scale-plate suspended by chains, is represented in the annexed cut. It appears, by the inscription on the beam, to have been made about the year 77 of our

era. A kind of steelyard is used by the Chinese for weighing very delicate matters, as gems and precious metals. From the manner in which the steelyard is mentioned in a curious tract published in 1578, it would appear that it was not at that time much known in England. The author recommends it for weighing charges for artillery, as being less troublesome than ordinary scales, owing to the use of but one weight, and that of small dimensions, and observes that the instrument was 'altogether used in South Spaine to wey all kinde of marchandise,' and that it was called 'statery.' (Bourne's *Inventions or Devises*, p. 45.)

The portable weighing-machine called the spring or pocket steelyard is noticed under SPRING-BALANCE, vol. XXII., p. 385.



Antient Roman steelyard, found at Pompeii, with part of the beam and inscription on a larger scale.

STEELYARD, MERCHANTS OF THE, a body of aliens who enjoyed various commercial privileges in England from an early period to the middle of the sixteenth century. 'The emperor's men,' mentioned in some ordinances of Ethelred II. (A.D. 978-1016) as trading to England, were the predecessors of the merchants of the Teutonic Gild. In 1220 the merchants of Cologne had a hall or factory in London for the legal possession of which they made an acknowledgment to the king. 'It seems that this Gildhall, by the association of the merchants of other cities with those of Cologne, became in time the general factory and residence of all the German merchants in London, and was the same that was afterwards known by the name of the German Gildhall (*Gildhalla Teutonicorum*)'. (Macpherson, *Annals of Commerce*, i. 383.) In 1235 Henry III. gave them permission to attend fairs in any part of England, and also to buy and sell in London, saving the liberties of the city; and they were exempted from several customs and payments. In the fifteenth century we find the Hanse merchants engrossing the privileges of the above antient incorporation, Cologne being a member of the League, and the whole of the German merchants resident in London probably belonging to one or other of the Hanse towns. At least, after 1475, they had but one factory in London, which was the Steel-yard, or Steel-house, as it was sometimes called, situate a little east of Dowgate, between Thames Street and the river. In 1475 Edward IV. entered into a treaty with the Hanseatic League, by which the privileges of the London factory were placed on a more secure foundation, instead of being granted only for a short period, and being at times curtailed and even occasionally suspended. By way of settling former disputes, it was thought worth while to pay them 10,000*l*., or rather to remit customs' duties on their goods to that amount. The king was to appoint two or more judges to act without the ordinary legal formalities in all civil and criminal cases between the Hanse merchants and English; and similar regulations were to be adopted in reference to English subjects residing at the Hanse towns. The fee simple of the Steelyard was conveyed by this treaty, also the Steelyard at Boston, and a house at Lynn. Under this treaty and their old charters the Hanse merchants of the Steelyard were enabled to monopolise certain branches of trade, in which they were exempted from duties payable by other traders; and by their combination and capital, they were doubtless formidable competitors in other branches of foreign trade; but though the activity of foreigners might be tolerated while native capital was wanting, yet a trade from which English merchants were virtually excluded could not possibly be permanent. Besides exciting popular indignation, the privileges of the Steelyard merchants were politically inconvenient, for when the direct trade with the Netherlands was stopped in 1493, large quantities of Flemish goods were imported from the Hanse towns into the Steelyard. On this occasion the journeymen and apprentices of London attacked the warehouses of the obnoxious Germans.

In 1505 a rival interest was created, by a charter granted to the Company of Merchant Adventurers for trading in woollen cloth to the Netherlands. The merchants of the Steelyard were bound in heavy penalties not to interfere with the trade of this new incorporation, which soon became a powerful rival not only to the German merchants, but to the merchants of the staple. In 1551 various allegations of the Merchant Adventurers, with the counter-statements of the merchants of the Steelyard, were put into the hands of the solicitor-general and the recorder of London, upon whose report the council came to a resolution that the Steelyard merchants had forfeited their privileges, their charters being contrary to the laws of the realm. The council reported that, no particular persons or towns being mentioned in these charters, the corporation had extended their privileges to whomsoever they pleased; that English subjects had not enjoyed reciprocity of privileges in the Hanseatic towns; that their English trade was no longer confined to the Hanse towns; that they had engrossed almost the entire trade carried on by foreigners in the kingdom; lastly, that they had reduced the price of wool, and also of corn by their importations of foreign grain. The articles which they imported, besides grain, are stated to have been cordage and other naval stores, flax and hemp, linen, cloth, and steel. The English Merchant Adventurers flourished on the ruin of the older incorporation, which however continued to linger until 1597, when the emperor Rudolph having ordered the factories of the English Merchant Adventurers in Germany to be shut up, Queen Elizabeth directed the lord mayor of London to close the house occupied by the merchants of the Steelyard. It is said that in 1554 Queen Mary had restored their privileges, and in a year or two afterwards withdrawn them, but the facts are not very clear on this point. [HANSE TOWNS; STAPLE.]

(Strype's *Eccles. Mem.*, iii. 77; Anderson's *Commerce*; Macpherson's *Commerce*.)

STEEN, JAN, one of the most celebrated painters of the Dutch school, was born at Leyden, in the year 1636. His father was a brewer, who, complying with his son's desire to be a painter, put him apprentice to Nicholas Knupfer, a German artist of considerable note, at that time residing at Utrecht. He afterwards studied under Van Goyen, who was so pleased with his agreeable manners, and his talents as a painter, that he gave him his daughter Margaret in marriage. Though Steen soon acquired great reputation, he did not gain sufficient to live with comfort, because he spent much time on his pictures, which he finished with extraordinary care. His father therefore advised him to set up a brewery at Delft, in which he had every prospect of success, but his propensity to an idle, intemperate, and dissolute course of life made him neglect his business, and having incurred debts, he was driven by necessity to his pencil. With the assistance of his relations he set up a

public-house, which was much frequented, but only gave him more opportunity and temptation to indulge in his intemperate way of life. The scenes which he saw here he transferred, often in a state of intoxication, with unrivalled skill to the canvas. None of his able contemporaries surpassed him in the naiveté of his compositions, in the expression and character of his figures, and the skilful distribution of light and shade. 'In spirit, humour, and invention,' says Dr. Waagen, 'Steen excels all other Dutch painters in the same line: to this is added a free, light, easy touch, a great freshness and clearness of colouring, and sometimes a delicacy of execution approaching if not equal to Metzen.' He sometimes attempted historical subjects, such as Moses striking the Rock, but it is in scenes of domestic life, of the higher as well as the lower classes, that he is without an equal. It seems that he also painted portraits. At Lord Spencer's seat at Althorpe there is a fine portrait of Sir Kenelm Digby ascribed to him.

After the death of his wife, by whom he had six children, he married a widow with two children. His business failed, and he was scarcely able to procure sufficient for his subsistence, by the sale and pawning of his pictures, which in his latter years were slightly painted. He died in 1689, leaving his family in the utmost distress. His works, which had not fetched great prices during his life, rose rapidly in value after his death, and are now greatly coveted, and sold at high prices. Several of his finest pictures are in England, in the collections of the Duke of Wellington, Lord Ashburton, Sir Robert Peel, Mr Hope, Mr Beckford, and in the private collection of his late majesty King George IV. His drawings are excessively scarce. He likewise executed a few very spirited etchings, which are also very scarce.

(Houbraken; Pilkington, by Fuseli; Bryan; *Conversations Lexicon*.)

STEENWYK, HENRY, the Elder, a celebrated painter, of the Flemish school, was born at Steenwyk in 1550. He studied under his father, who was well versed in painting, architecture, and perspective; and also under John Fredemann, called De Vries. Like his master, he painted architectural subjects; but excelled him and all his contemporaries in truth, delicacy, transparence, and neatness. His favourite subjects were the interiors of magnificent Gothic churches and convents, and most frequently views by night, when they were illuminated by flambeaux or tapers. He was a consummate master of chiaroscuro, and his lights and shadows are distributed with the greatest judgment. The reflections of his lights are beautiful, and every column, cornice, and other member of the Gothic architecture is represented with the most perfect truth and precision. His pictures are usually enriched with figures by Breughel, Van Tulden, and other distinguished artists. His genuine works are extremely rare, and very highly prized all over Europe. To avoid the troubles of war, he retired to Frankfort, where he died in 1603 or 1604.

STEENWYK, HENRY, the Younger, the son of the preceding, was born in 1585. He followed the style of his father, by whom he was very carefully instructed, and very good judges have thought that he often equalled or even surpassed him. His friend Vandyck, for whom he often painted the architectural and perspective backgrounds of his pictures, induced him to visit England, and introduced him to the court of Charles I., where he met with the encouragement due to his talents, and found employment in this country for several years. He died at London, when still young, but in what year is uncertain. His widow, who had been instructed by her husband, retired to Amsterdam after his death, and practised painting there: her works were greatly esteemed and readily purchased at high prices. The celebrated Peter Neefs, father and son, were among the disciples of the elder Steenwyk. The portrait of the son by Vandyck is engraved in the collection of the portraits of the chief artists of his time.

STEER. [Ox, p. 73.]

STEEVENS, GEORGE, was born at Stepney, in 1736. His father was connected with mercantile pursuits in London, being a director of the East India Company. George Steevens was placed on the foundation at Eton, and became a scholar of King's College, Cambridge, in 1754. His first publication, and a most useful one, was the reprint, in four volumes, octavo, of 'Twenty of the Plays of Shakespeare, being the whole number printed in quarto during his Lifetime,' &c. These plays profess to be literal copies of these rare editions; and in several instances the various readings of other quarto editions are given in the foot-notes. This was an acceptable service to all students of our great poet; and a comparison of many of these plays with the originals enables us to say that the reprints are remarkably faithful. This reprint appeared in 1766. The reputation which Steevens thus acquired led, no doubt, to his association with Johnson in the edition of Shakspere which appeared in 1773 with their joint names. In this edition his assistance was of essential service: for he brought to the task of editing Shakspere qualities in which Johnson was deficient—a more accurate knowledge of early English literature, and greater precision in verbal criticism. Neither his character nor that of the age to which he belonged would have led him to any complete conception of Shakspere's excellence; but what he professed to do, he did satisfactorily. He collated all the copies diligently; he restored many readings which had been tampered with by his editorial predecessors; and he judiciously adhered to the old copies, without attempting to regulate the metre according to the poetical creed of his day. In 1778 the second edition by Johnson and Steevens appeared, in which Malone had rendered some assistance; but Malone, in 1780, published a supplement containing the doubtful plays and the poems. This appeared something like a setting up on his own account; and Steevens, who thought too highly of himself to pay much respect to others, scarcely forgave this. He and Malone at length became rival editors, each working with very laudable diligence in that species of commentary which resulted from their antiquarian knowledge; but each very incapable of throwing any new light upon the poet by a genial admiration and a philosophical estimate of his wonderful performances. Their rivalry, in all probability, gave a new direction to the labours of Steevens. He dedicated himself to the production of another edition, in which he should cast aside the principles which had guided his former labours. He possessed a more decided and more acute mind than Malone; and, with an ill concealed contempt of the plodding diligence of his old fellow-labourer, he went to work to give us a new Shaksperian metre, such as would satisfy the most precise disciple of the ten-syllable school. He proposed, 'instead of a timid and servile adherence to antient copies,' to proceed to the 'expulsion of useless and supernumerary syllables, and an occasional supply of such as might fortuitously have been omitted.' The edition in which this process was perfected was produced in 1793, in fifteen vols.; and such was his commendable anxiety for its correctness, that he often walked from his house at Hampstead to his printer's in London, before day-break, that he might correct the proof-sheets. His experiment was perfectly successful with a public not very critical, who were thus presented with what he called 'a commodious and pleasant text of Shakespeare.' That text remained undisputed in its authority till the publication of Malone's posthumous edition by Boswell in 1821, in which some attempts were made to adhere to the early copies; and no popular edition, conducted upon a different principle, appeared till that of Mr. Knight, in 1838. In his edition of 1793 Steevens made his well-known avowal that he did not reprint the poems of Shakspere, 'because the strongest act of parliament that could be framed would fail to compel readers into their service.' With the exception of his various editions of Shakspere, Steevens did not apply himself to any extensive work. He assisted Nichols in his 'Biographical Anecdotes of Hogarth,' and Isaac Reed in the 'Biographia Dramatica.' His ample means put him above the necessity of literary labour. But his leisure was amply filled up by a system of excitement, which was not calculated to add to his happiness or his reputation. He had the command, which his acuteness and sarcastic power might easily secure, of a newspaper and a review; and the 'St. James's Chronicle' and the 'Critical Review' were made the vehicles of the bitterest attacks upon the literary characters of those to whom in private he was all smiles and courtesy. In some satirical verses, as malignant as his own paragraphs, and rather coarser, we have this character of him (Nichols's *Literary Anecdotes*, viii., 540):—

> 'Mark the old beau's grimaces, his smirk and palaver;
> Mark his crest and fine folds, but beware of his *slaver*.'

Johnson said of him, in answer to Beauclerk's assertion 'He is very malignant,' 'No, Sir, he is not malignant. He is mischievous, if you will. He would do no man an essential injury; he may indeed love to make sport of people

by vexing their vanity.' This, most probably, was the true state of the case. Steevens had no domestic ties, and men were afraid of him. Johnson said, on another occasion, in which there is little doubt he alluded to him, 'Sir, he lives like an outlaw.' His mock praise, his sarcastic politeness, his anonymous ridicule, gratified his sense of power. He had higher abilities and more scholarship than many of the solemn critics who were then busied about our early literature: for then, as it always must be, the small men, who applied themselves to verbal criticism, fancied themselves great (to use Bentley's forcible image) when they were on a giant's shoulders. While Steevens, in his own notes on Shakspere, is making the most profound bows to this man's learning and that man's ingenuity, we can see him winking as it were upon his readers, and whispering, 'what owls!' Amongst other tricks, he set up mock commentators, under the names of Amner and Collins, to perpetrate dirty annotations; and he once signed a bitter attack on Capell, in his own edition, with the name of his timid rival Malone. George Steevens died at Hampstead, in January, 1800; and was buried at Poplar, where his memory is graced by one of Flaxman's monuments.

STE'FANO (called *Fiorentino*) was born at Florence in 1301. Though his most celebrated works, in the church of Ara Coele at Rome, Santo Spirito at Florence, and elsewhere, are no more, he deserves to be mentioned as a disciple of Giotto, and the only one who attempted something beyond the mere imitation of his master, whom, according to Vasari, he excelled in every department of the art. He was Giotto's grandson, by a daughter named Caterina. He was the first who attempted foreshortening, and if he did not completely succeed in this, he certainly made improvements in perspective, and gave new variety of character and life to his heads. No authenticated picture of his remains in Tuscany, 'unless,' says Fuseli, 'we except a Madonna, in the Campo Santo of Pisa, undoubtedly in a greater style than the works of his master, but retouched.'

STE'FANO, TOMMASO DE, supposed to have been the son and pupil of the preceding, was called Giottino, from the resemblance of his works to those of Giotto. A Pietà, at S. Remigi at Florence, and some frescoes of his at Assisi, bear indisputable marks of that style.

STE'FFANI, AGOSTI'NO, an Italian composer of great eminence in the seventeenth century, was born, about the year 1650, at Castello Franco. In his youth he was entered a chorister at St. Mark's, Venice, where a German nobleman pleased with his singing and appearance, obtained his discharge from the church, took him into Bavaria, there bestowed on him a most learned and liberal education, the musical part of it under Ercole Bernabei, and finally, when he had arrived at the proper age, got him ordained, and thenceforward he took the title of *abate*, or abbot, by which he is now commonly known. His ecclesiastical compositions soon became numerous, were much admired, spread his fame, and attracted the notice of Ernest, duke of Brunswick, father to George I. of England, who, though a Protestant, invited the Roman Catholic and clerical musician to Hanover, made him director of his chamber music, and committed to him the management of the opera, then just beginning to raise its head in Germany. But the intrigues of singers at length wearied him of his theatrical and rather incongruous occupation, though not till he had composed several operas, which, translated from Italian into German, were performed at Hamburg from the year 1694 to 1700. These however are forgotten; but his madrigals, motets, and, more especially, his duets, of which Caroline, consort of George II., collected nearly a hundred, are the best known of all his works, and of which it is enough to say, that Handel acknowledged his twelve celebrated duets to have been written in imitation of them.

Steffani was not only a musician but a statesman. He had a considerable share in concerting, with the courts of Vienna and Ratisbon, the scheme for erecting the duchy of Brunswick-Lünenburg into an electorate, for which service the elector assigned him a handsome pension, and Pope Innocent XI. gave him the bishopric of Spiga. In consequence of this he no longer put his name to his compositions, but adopted that of his secretary, Gregorio Piva; and in 1708 relinquished his appointments in Hanover in favour of the, afterwards, great Handel. He died at Frankfort, in the year 1729.

STEIBELT, DANIEL, a celebrated composer for, and performer on, the piano-forte, was born at Berlin, in 1755, where his father was a manufacturer of musical instruments. When a youth, attracting the notice of William III. of Prussia, he was educated at the charge of that monarch, and soon distinguished himself. In his travels he visited Paris and London. In the former city he had the honour to introduce Haydn's *Creation*, and also published many works. In the latter he made a considerable stay, took many pupils, and produced and printed much piano-forte music. He afterwards returned to his native country, and finally settled at St. Petersburg, where he was appointed *maître de chapelle* to the emperor. He there died, in 1823, in distressing circumstances, for he had lived thoughtlessly, to use a very mild epithet. Steibelt may almost be said to have formed a piano-forte school, to which the term *sparkling* may be applied. His best compositions are remarkable for brilliancy, and what we will venture to call picturesque effect, and his execution of them was singularly delicate, animated, and beautiful. He composed also some operas, which were performed in Paris and in St. Petersburg, but these did not survive their author.

STELLA'RIA (from *stella*, a star), the name of a genus of plants belonging to the natural order Caryophylleæ, and the section Alsineæ. The calyx has 5 sepals, the corolla is composed of 5 petals, which are either bifid or bipartite; the stamens are 10 in number; the ovary simple, with indefinite ovules; styles 3, and the fruit a capsule with six valves. There are 67 species of this genus enumerated. Most of them are weeds, which are distributed over all parts of the world. Eight of them are found in Great Britain. In common with the whole order to which they belong, they possess no active properties. Few of them are thought worthy of cultivation, and when planted in gardens they require but little care.

S. Holostea, the greater Stitchwort, is a British species, and is the handsomest plant of the genus. It has a nearly erect stem; lanceolate, acuminated, finely serrated leaves; inversely heart-shaped bifid petals, twice as long as the calyx. It is often planted in gardens as a border flower, for which, on account of its early delicate white flowers, it is well adapted.

S. media is the common chickweed, which is so common and abundant on road-sides and waste places all over Europe. It is characterised by its procumbent stems possessing an alternate line of hairs between each pair of leaves. It has small white flowers, which are open almost all the year. It is frequently eaten as a pot-herb, and small birds are very fond of its seeds.

S. cerastoides, and *scapigera*, the Alpine and many stalked stitchworts, are both of them British plants, and are sometimes cultivated in pots.

STELLA'TÆ, the name of a natural order of plants formed by Ray. The verticillate arrangement of the leaves of the plants of this order gives them a starlike appearance, whence the name. The order is called by Lindley Galiaceæ. [GALIACEÆ.]

STELLENBOSCH. [CAPE OF GOOD HOPE.]

STELLE'RUS, Cuvier's name for a genus of *Herbivorous Cetacea*, *Rytina* of Illiger. [WHALES.]

STE'LLIO, Cuvier's name for a genus of IGUANIANS, under which he arranges the following subgenera:—*Cordylus*, *Stellio*, *Doryphorus*, *Uromastix*, *Agama*, *Trapelus*, *Leiolepis*, *Tropidolepis*, *Leposoma*, Spix (*Tropidosaurus*, Boie), *Calotes*, *Lophyrus*, *Gonocephalus*, *Lyriocephalus*, *Brachylophus*, and *Physignathus*.

Cuvier defines the *Stelliones* to be those Saurians which have, with the general characters of the *Iguanians*, the tail surrounded by rings composed of great scales which are often spiny.

Mr. G. E. Gray places *Stellio* under the family *Agamidæ*, together with the following subgenera, which are included in Cuvier's arrangement:—*Uromastix*, *Agama*, *Trapelus*, *Leiolepis*, *Calotes*, *Lophura*, *Goniocephalus*, *Lyriocephalus*, and *Physignathus*. [AGAMA; REPTILES; SAURIANS.]

STELLIONATE, a word derived from *stellio*, the name of an animal of the lizard kind, mentioned by Pliny (*Hist. Nat.*, l. 3, c. 10), and by Virgil (4 *Geor.*, 243), is a term used in the Roman law to denote all such crimes, in which fraud is an ingredient, as have no special names to distinguish them, and are not defined by any written law. In general, wherever a civil action might be brought on the ground of fraud, there might be a criminal prosecution for

stellionate. The term however is chiefly applied to cases where a person sells, exchanges, or transfers to one, property with respect to which he has already entered into a contract with another. It is also applied to cases of pledging another man's property, substituting base for precious metals, dealing in counterfeit or adulterated goods, and generally to the practice of any species of imposture. The punishment of stellionate was of necessity discretionary. Where the criminal was a person of distinction, the ordinary punishment appears to have been temporary banishment and degradation from his rank; and where he belonged to the lower orders, it seems to have been competent to inflict any punishment short of condemnation to work in the mines. (*Dig.*, 47, tit 20; Hellfeld, *Jurispr. For.*, s. 2067.) The term stellionate is used in the law of Scotland in nearly the same sense as in the Roman law. (Ersk., *Inst.*, 4, tit. 4, s. 79.)

STELLIRIDIANS, M. de Blainville's name for the third order of his *Actinozoaria*, comprehending those radiated animals which are commonly known as *Star-fishes*, or *Sea Stars*, and may be arranged under the great genus ASTERIAS of Linnæus.

The following is M. de Blainville's definition of the order:—

Body generally depressed, wide, and regularly formed, at its circumference, into angles which are more or less sharp, often prolonged into lobes or rays perfectly similar, covered with a skin more or less sustained by calcareous pieces.

Intestinal Canal provided with a single buccal orifice,* unarmed, but surrounded by tentaculiform suckers.

Ovaries radiated and opening at the margin of the mouth.

M. de Blainville remarks that this extremely natural order corresponds almost exactly to the genus *Asterias* of Linnæus: but it has become necessary to add to it the *Encrini*, which the latter author had arranged as species of *Isis*, or *Pennatula*.

The character of the order, according to M. de Blainville, rests—

1. On the nature of the skin, which is more or less flexible, although solidified by very diversiform, calcareous pieces, and which present, at the buccal surface, a sort of vertebral disposition serving for locomotion.

2. On the absence of the anus from the intestinal canal, which last is no more than a stomach more or less lobated at its circumference.†

3. On the constant termination of the ovaries, disposed in rays, at the circumference of the mouth.

As to the form of the body, M. de Blainville admits that it is often very different, although it is always at least regularly polygonal; in fact, he adds, these angles, which are sometimes very obtuse, can be developed so that in the family of the *Ophiuræ* and *Comatulæ* they become true appendages in the form of long rays, sometimes even divided or dichotomized. This disposition has led to the comparison of these animals with stars.

Geographical Distribution.—Very wide. Few or no seas are without some species of the order.

ORGANIZATION.

Digestive System.—The nutritive apparatus of the Stelliridians is very simple; presenting in most of the family a single orifice destitute of teeth in the centre of the lower surface of the body, performing the functions both of the mouth and the anus: but in some presenting a digestive cavity with an orifice for the evacuation of its contents distinct from that by which the food is taken in. In the catalogue of the Physiological series in the museum of the Royal College of Surgeons in London, there are examples of both these modifications.

Illustrative of the first section, consisting of those star-fishes which have the digestive cavity simple, or without distinction of stomach and intestine, receiving and expelling its contents by the same orifice, we find No. 432, a preparation of a star-fish (*Asterias papposa*, Linn.; *Stella dodecactis*, Link; *Asterias helianthoides*, Pennant; *Stellonia papposa*, Agassiz; and *Solaster papposa*, Forbes). It exhibits the central orifice of the digestive cavity, and a portion of the integument has been reflected on the opposite side of the body, to show the numerous cæca continued from the digestive cavity. No. 433 presents a vertical section of the same species, showing the interior of the same cavity. In No. 434 the integument has been removed from the whole of the anterior part of the body of an *Asterias rubens*, Linn. (*Asterias glacialis* and *Asterias clathrata*, Penn.; *Stellonia rubens*, Ag.; *Uraster rubens* of the same, Forbes), showing the membranous digestive cavity, containing some small bivalves. No. 435 is a specimen of *Asterias discoidea*, Lam., from which two rays have been removed, showing the singular and beautifully ramified form of the digestive cavity. The membranous pouches appear to be given off in two series, are sacculated, and strung, as it were, upon a mesentery.

The second modification is shown in No. 435 A, which presents the body of a star-fish (*Alecto glacialis*, Leach). Here the alimentary canal is continued in a spiral direction from the central orifice or mouth, and terminates by a second direct orifice or anus, situated at the extremity of a fleshy tube, which projects forwards by the side of the mouth.

M. de Blainville states that the liver is apparent and rather considerable in the star-fishes; it occupies the circumference of the stomach, forming bunches or *racemi* (des espèces de grappes), which are prolonged more or less into the cavity of the appendages when there are any; at least, he observes, such is the opinion of Cuvier, who is followed by Spix and Meckel. Delle Chiaje, on the contrary, regards these organs as a kind of stomachal cæca (and such an opinion seems to be strengthened by the preparations above noticed), and thinks that the liver is an irregular organ, situated on the upper part or dome of the stomach, of which no other author, according to M. de Blainville, makes mention, and which he himself had not observed. This organ is a racemose little bag of a yellowish-green or yellow colour, and its contents present a similarity to bile both to the sight and taste.

Food.—The very dilatable mouth and gullet of the star-fishes is admirably adapted for securing the testaceous mollusks and other animal substances on which the family feed. When the prey is apparently disproportioned to the parts into which it is to be conveyed, the œsophagus or gullet, together with part of the stomach itself, can be protruded and everted so as to draw the desired food into the cavity by the application of the everted surface to it. Thus the shell-fish is swallowed whole, and specimens still living have been taken from the cavity. At other times the juices of the prey are sucked out, and the exhausted bivalve is left dead with its shell gaping. Not that the old supposition that the star-fish succeeded, in this last mode of feeding, by inserting a ray or finger into the gaping shell, and if it found the bivalve too strong for it, got rid of the difficulty and the ray at once, conscious of its power of reproducing another, seems to be at all founded in fact. Star-fishes have been detected in the act of sucking the juices of conchifera through perforations, and also with their mouths applied to the edges of the valves. From the apparently paralyzed state of the bivalves found in such situations, it has been conjectured that the star-fish introduces some deleterious secretion within the valves, and thus leaves the mollusk torpid and deprived of the power of closing its valves against the attacks of its destroyer. Star-fishes are considered, and not without reason, as great enemies to oyster-beds. [ASTERIAS, vol. ii., p. 515.] But it is not on living prey alone that the star-fishes feed. They seem to assist materially in cleansing the sea from dead and decomposing animal matter. A human tooth has been found in the stomach of a star-fish.

Respiratory System.—Although there does not appear to be any special organ for respiration in the Stelliridians, the oxygenization of the circulating fluid is extensively provided for by the exposure of the peritoneal cavity, and all the viscera, to the sea-water, which is freely admitted through membranous pipes, which have thence obtained the name of respiratory tubes. 'These,' says Dr. Sharpey, 'communicate at their base with the interior of the body, and are perforated at the summit by an orifice which can be very accurately closed. Most of them are placed in groups or patches, and opposite each group the fibrous membrane, forming the wall of the body, presents on its inside a shallow pit perforated with holes, through which the tubes communicate with the internal cavity. The tubes are formed externally of the superficial layer of the skin, and are lined in the inside by a prolongation of the peritoneal membrane. This membrane lines the parietes of the body, and is reflected over the contained parts; at least it

* *Comatula* (*Alecto*, Leach) is an exception.
† But note the exception above alluded to.

covers the stomach and cæca, and probably also the ovaries and vesicles of the feet; opposite the perforated pits it sends prolongations through the holes into the tubes, as may be easily seen on stripping off a portion of it. There can be no doubt that sea-water enters the peritoneal cavity. The animal slowly distends itself with that fluid, and again, but at no stated interval, gives out a portion of it. This is obvious from the fact that the same animal may be seen distended at one time and flaccid at another. Naturalists are generally of opinion that the water enters and issues by the respiratory tubes, and indeed no other orifices have been discovered; we must however freely own that we have never been able actually to observe its passage through these tubes. The peritoneal membrane seems to be the principal seat of respiration; spread over the viscera and the parietes of their containing cavity, and lining the respiratory tubes, it presents a great extent of surface continually in contact with the surrounding medium; and we have found that a beautiful provision exists for maintaining currents of water along the membrane, and thus effecting that constant renovation of the fluid in contact with its surface, which is required in the respiratory process. These currents are produced by means of cilia. Ciliary currents take place also on the external surface of the body, which probably partakes in the process of respiration; we have moreover observed them within the tubular feet, and on the internal surface of the stomach and cæca. In this last situation they are probably subservient to digestion.' (*Cyclopædia of Anatomy and Physiology.*)

Circulating System.—Tiedemann and Delle Chiaje are the authorities from whom a knowledge of the circulating system of the Stelliridians is principally derived: but this part of the organization of these animals is so obscure, that we need not be surprised at the difference which exists in the views of those observers. Thus, the true sanguiferous system is, according to Tiedemann, restricted in a great measure to the alimentary organs and ovaries, and he consequently supposes that the ducts which convey the fluid supplied to the feet, afford nutrition to other parts of the body. In other words, he recognises two distinct systems of nutrient vessels; one a true sanguiferous system, consisting of vessels which carry blood, and the other a set of vessels (those of the feet) conveying a nutritious fluid secreted from the blood.

Delle Chiaje contends that the two orders of vessels above alluded to intercommunicate, and so form but one system.

Dr. Sharpey is disposed to conclude, from his own observations, that the vessels of the feet form a system apart from the blood-vessels, as Tiedemann maintained; but he observes that there is considerable reason to doubt whether, as that author supposes, they serve as the nutritious vessels of the parts in which they run; for, according to Tiedemann's description, it does not appear that they ramify in the tissues. Moreover, Dr. Sharpey adds, their contained liquid does not present the usual characters of blood, or of a fluid adapted to nourish the textures. He admits it to be true that there are floating particles suspended in it, but he states that the clear fluid, when filtered, yields no trace of animal matter, but agrees almost entirely in composition with sea-water. Such, at least, was the result of Dr. Sharpey's examination of it in the *Asterias;* and he proceeds to give an account of the proper sanguiferous system, following Tiedemann as his leading authority, but, at the same time, stating the more material points in which Chiaje differs from him, thus—

'In *Asterias,* a delicate vessel runs along the upper surface of each of the cæca. There are of course ten such vessels in *Asterias aurantiaca* (from which the description is taken), corresponding in number with the cæca. They commence near the extremity of the rays, and, receiving branches from the branches and lobes of the cæca, proceed to the central part of the animal, where they terminate in a circular vessel which runs round the upper part of the body on the internal surface. The circular vessel also receives ten branches from the ovaries, and five from the stomach, which, before joining it, unite into two. The vessels described seem to constitute the venous system, and Tiedemann further supposes that the cæcal and gastric veins convey the chyle or nutritious part of the food from the alimentary organs. The circular vein opens into a vertical canal, which descends along the prominent angle between the two rays, inclosed in the same membranous sheath with the sand canal, and terminates in an inferior circular vessel. The descending canal is dilated in the middle; its comparatively thick, brown-coloured parietes are smooth externally, but reticulated on the inside and composed of interlaced fibres, which Tiedemann found to possess muscular irritability. He accordingly considers this canal as the heart. The inferior circular vessel (which must not be confounded with the circular canal connected with the feet) surrounds the mouth on the outside or inferior surface; it sends out five branches which pass into the interior of the body, and are distributed to the stomach, cæca, and ovaries. Tiedemann regards these branches, with the circular vessel from which they proceed, as arteries, and he thinks it probable that their minute ramifications open into the radicles of the veins, though from their delicacy he has not been able to ascertain the fact by injection. Tiedemann's view of the function of the respective vessels is derived solely from a consideration of their anatomical disposition, and while in the same way it may be inferred that the blood circulates in a direction conformable with this view, it must nevertheless be kept in mind that no direct physiological proof of such a course of the blood has been yet obtained. Besides the vessels described, Tiedemann found yet another circular vessel surrounding the mouth on the under surface, and placed more superficially than the last-mentioned; it is of an orange colour, and sends a branch along each of the rays in the groove which is on the middle of their inferior surface. He could trace no connection between this vessel or its branches and the rest of the vascular system, and he professes himself at a loss to conjecture what may be its function.'

'According to Delle Chiaje, the circular vessel into which the canals of the feet open receives also the veins from the upper surface of the cæca and stomach. The same vessel, which he names the venous sinus, gives out:—1, twenty short *dental* arteries; 2, the *mesaraics* to the under surface of the cæca; 3, five *vertebral* arteries which open into the vesicles of the feet; 4, the *radial* to the under part of each ray; 5, the *dorsal* arteries to the upper part of the ray, which extend their ramifications to the external surface of the body.' (*Cyclopædia of Anatomy and Physiology.*)

Nervous System and Senses.—Professor Owen, in his preface to the third volume of the *Descriptive and Illustrated Catalogue of the Physiological Series of Comparative Anatomy contained in the Museum of the Royal College of Surgeons in London,* remarks that when the nervous system begins to be distinctly eliminated in the form of fibres, it is accompanied by a distinct development of the muscular system; and the digestive canal is provided with a proper contractile tunic, and floats freely in an abdominal cavity. He observes that the nervous fibres in the classes of animals in which they are first discernible proceed from a ganglion or ganglions in the neighbourhood of the mouth, and extend in a radiated or longitudinal direction according to the form of the body, but are not afterwards brought into communication by ganglionic masses.

'The Echinoderms, as the Star-fish and Sea-Urchins,' writes the Professor, 'first present these conditions of the nervous, muscular, and digestive systems. A very gradual transition from the radiated to the elongated form is traceable from this class through the *Holothuriæ* and *Sipunculi* to the cavitary *Entozoa* or *Cœlelmintha* (intestinal worms having an abdominal cavity), and thence to the *Epizoa* and *Rotifera,* which make a near approach to the annulose division of the animal kingdom; but at the same time do not possess that structure of the nervous system which is its true characteristic. The four classes of animals, thus distinguished by a common character of the nervous system from the *Acrita* on the one hand, and the *Articulata* on the other, constitute a second division of the animal kingdom, which may be termed *Protoneura.*'

The preparation No. 1292 A, in the series illustrative of the nervous system of the *Nematoneura* is a star-fish (*Asterias papposa,* Lam.) with the membrane removed from the oral surface of the central disk, to show the simple nervous chord surrounding the mouth and distributing filaments to each ray. These filaments run in the interspace of the tubular feet, extending from between the spines which protect the ambulacral grooves. (*Catalogue.*)

Tiedemann, who discovered the nervous system in these animals, describes it in *Asterias aurantiaca* as composed of a delicate white chord surrounding the mouth, in form of a ring immediately on the external side of the circular vessel

into which the heart opens, and of filaments arising and diverging from the annular chord opposite to the rays—three filaments for each ray—one running along the under surface in the median line, and appearing to send small branches to the feet; the other two, shorter, passing between the first and second segment of the ray into the interior of the body, and probably distributed over the stomach. No ganglia were discovered by Tiedemann, but minute ganglia have been described by others as existing at the points whence the diverging filaments spring. (Grant's *Comp. Anat.*)

Touch.—All of course agree in assigning the sense of touch to the star-fishes, but many would confine their endowment to that sense. Professor Ehrenberg however, who is a keen and accurate observer, is disposed to think that some of them, at least, are gifted with visual organs under the form of a single red speck at the termination of each ray. These specks had been long noticed, but without any determinate conjecture as to their use in the animal economy, till he, struck by their outward resemblance to the eyes of the *Entomostraca* and *Infusoria*, thought that they might be organs of sight, and he traced the long nerve of one ray up to the extremity, where it enlarges into a sort of ganglion connected with the red speck.

Mr. Rymer Jones, after noticing the nervous system of these animals, thus expresses his dissent from Professor Ehrenberg's views:—

'Such an arrangement can only be looked upon as serving to associate the movements performed by the various parts of the animal, for no portion of these simple nervous threads can be regarded as being peculiarly the seat of sensation or perception. But this inference is not merely deducible from an inspection of the anatomical character of the nerves: it is based upon actual experiment. We have frequently, when examining these animals in a living state—that is, when, with their feet fully developed, they were crawling upon the sides of the vessel in which they were confined—cut off with scissors successive portions of the body so as to expose the visceral cavity; but so far from the rest of the animal appearing to be conscious of the mutilation, not the slightest evidence of suffering was visible: the suckers placed immediately beneath the injured part were invariably retracted: but all the rest, even in the same ray, still continued their action, as though perfectly devoid of participation in any suffering caused by the injury inflicted. Such apathy would indeed seem to be a necessary consequence resulting from the deficiency of any central seat of perception whereunto sensations could be communicated: nevertheless Ehrenberg insists upon the existence of eyes in some species of the star-fish, attributing the function of visual organs to some minute red spots visible at the extremity of each ray, behind each of which he describes the end of the long nerve which runs along the ambulacral groove as expanding into a minute bulb. We must however confess that the proofs adduced in support of such a view of the nature of these spots, appear to us to be anything but satisfactory; and as we have already stated in the first chapter the physiological objections which may be urged against the possibility of any localised organ of sense being coexistent with a strictly nematoneurose condition of the nervous system, they need not be repeated here. The general sense of touch in the *Asteridæ* is extremely delicate, serving not only to enable them to seize and secure prey, but to recognise its presence at some little distance, and thus direct these animals to their food. A person who has been in the habit of fishing with a line in the shallow bays frequented by star-fishes, and observed how frequently a bait is taken and devoured by them, will be disposed to admit this; yet to what are we to attribute this power of perceiving external objects? It would seem most probably due to some modification of the general sensibility of the body, allowing of the perception of impressions in some degree allied to the sense of smell in higher animals, and related in character to the kind of sensation by which we have already seen the *Actiniæ* and other polyps able to appreciate the presence of light, although absolutely devoid of visual organs.' (*General Outline of the Animal Kingdom and Manual of Comparative Anatomy.*)

Mr. Forbes, although he admits that the existence of ganglions in the nervous system of these animals is generally regarded as doubtful, seems, from the frequent recurrence of the terms 'eye' and 'eyelid,' to be of opinion that the specks above alluded to are visual organs. (*History of British Star fishes and other Animals of the Class Echinodermata.*)

Our own opinion and observation are in favour of the views of Ehrenberg: and we think that those who have accurately watched the star-fishes which are furnished with these specks on the sea-coast will in general be irresistibly led to the conclusion that the organs, though not eyes in the strict sense of the term, serve the purposes of vision modified to the exigencies of the animal, enabling it to seek or avoid objects according to its will. Nor does analogy, in our view of the case, present any difficulty. We have only to consider that the centre is a head as well as a stomach, a condition that will hardly be denied to it, and the rays proceeding from it may be viewed as so many antennæ—(take those of the snail for example, with their terminal ocular points, as in some degree analogous)—with visual dots at their extremities. This, at all events, may solve the problem of the destructive visitation of these animals to the baited line, more in unison with the analogies than the supposed existence of a general olfactory sense, of whose presence not the slightest trace has been observed.

Locomotive System.—The organs of motion in the *Stelleridans* are various. The rays themselves are moveable; and in the free Stelleridans aid in the removal of the animals from place to place. Thus the common star-fish can bend its rays towards the upper or towards the lower surface of the centre or disk, and can approximate some whilst it extends others: so that they are widely divaricated laterally, and thus facilitate its advance in the water, or its passage through small spaces. In the common star fish these motions are slow, but in *Ophiocoma* they are comparatively rapid, and manifested in active contortions on some occasions. According to M. Sars, the young of *Asterias Sanguinolenta*, which have four short club-shaped appendages or arms at their anterior extremity, move slowly but uniformly in a straight line with their fore-arms foremost. Vibratile cilia are supposed to form the moving power in this case: the arms also enable the little animal to creep at a slow pace along the rocks. When the animal is more fully developed (post, p. 15) the power of swimming ceases.

Tiedemann considers that the power of moving the rays resides in the contractile skin. Meckel states that there are distinct muscles leading between the calcareous plates which form the floor of the rays. Dr. Sharpey has no doubt that the motions are partly effected by the skin, but he had himself observed a distinct band of muscular fibres running along the roof of each ray, between the coriaceous skin and peritoneal membrane when it is stript off.

But the principal locomotive organs of the free Stelleridians, as well as of the *Echinodermata* generally, are the membranous tubes which can be protruded at will through the ambulacral apertures, and which have been termed the feet. The clearest description of this complicated and in some degree obscure apparatus known to us is that by Dr. Sharpey; and we therefore give it in his own words.

'These,' writes Dr. Sharpey, treating of the membranous tubes or feet,' are very numerous, and are usually disposed in regular rows: they contain a clear fluid, which is conveyed to them by a peculiar system of vessels. Each foot consists of two parts, an internal and generally vesicular portion placed within the body, and a tubular part on the outside, projecting from the surface, and continues with the first through an aperture in the skin or shell. The tube is closed at the extremity, and terminates there in a sucker, which has usually the form of a disk slightly depressed in the centre. Both parts of the foot are evidently muscular, the fibres of the tubular portion being disposed in a circular and longitudinal layer; the cavity is lined with a transparent membrane, and the tubular part moreover receives an external covering from the epidermis. The foot is extended by the contraction of its internal vesicle, which forces the fluid into the tube; or when a vesicle is wanting, by the projection of a fluid into the tube from a communicating vessel. The tubular part is thus distended and elongated: it retracts itself of course by its muscular fibres; and when this takes place, the fluid is forced back again into the vesicular or internal part. In progression the animal extends a few of its feet in the direction in which it desires to go, attaches the suckers to rocks, stones, or other fixed objects immediately in advance; then shortening its feet, it draws its body in the wished-for direction. In the star-fish the feet are disposed in rows along the under surface of the

ing, diminishing in size as they approach the extremity. There are usually two simple rows in each ray, and the vesicular part is for the most part deeply cleft into two lobes, as in *Asterias aurantiaca.* In other cases, as *Asterias rubens*, there are two double rows in every ray, and each foot has a round undivided vesicle. The canals or vessels which convey the fluid to and from the feet are all connected with a circular vessel situated in the vicinity of the mouth. This vessel lies immediately within the calcareous ring already described as connecting the rays at the commencement; from it a straight canal proceeds along the floor of each ray in the median line, and in its progress gives off lateral branches, which open into the vesicles of the feet. There are moreover connected with the circular vessel—First, a certain number of bodies (ten in five-rayed species), which Tiedemann compares to glands; they are very small, brown, sacculated organs, each opening by a small orifice into the circular vessel: Tiedemann supposes them to be the source from which the fluid filling the feet is derived.—Secondly, pyriform sacs: in *A. aurantiaca* there are four groups of these; and each group consists of three or four sacs, which open by a common tubular pedicle into the circular vessel. In some other species there are five simple sacs. They are muscular, and Tiedemann conceives them to be the chief agents by which the fluid is forced into the vesicles of the feet, to which they are placed in a sort of antagonism. It would seem however that this purpose may be accomplished by other means; for, according to Meckel's statement, and, we may add, our own observation, they are not present in all species.—Lastly, the circular vessel receives the singular organ named the stone-canal or sand canal by Tiedemann, who describes it as a membranous canal containing a friable mass of sandy or earthy matter, which commences by a wide origin on the inferior or internal surface of the calcareous disk already described as situate on the upper part of the body, descends in a duplicature of fibrous membrane, and opens by a narrow orifice into the circular vessel, the upper or wide end being closed by the disk. Ehrenberg has correctly remarked that this organ is not filled with an amorphous mass of earthy or cretaceous matter: he describes it as exhibiting a dense network of calcareous fibres, with hexagonal and pentagonal meshes, resembling, in some respects, the cavernous structure of the penis. The result of our own examination, in more than one species, is different still. We have always found the earthy matter forming a jointed calcareous tube. This tube, which is about the thickness of a surgeon's probe, is composed of rings of calcareous substance connected by membrane, so that viewed externally it is not unlike the windpipe of a small animal. On cutting it across however it is found to be more complex in structure than appears externally; for it contains within two convoluted laminæ of the same nature as its calcareous parietes. These laminæ are rolled longitudinally: they rise conjointly, or as one, from the internal surface of the tube, pass inwardly a certain way, then separating, are rolled in opposite directions, something after the same manner as the inferior turbinated bone of the ox. These internal laminæ become more convoluted towards the upper end, where at last they, as well as the more external part of the tube, join the dorsal disk, appearing gradually to become continuous with its substance. The disk is perforated with numerous pores, which open into the tube. Tiedemann conceives the function of the sand-canal to be that of secreting the earthy matter required for the growth of the calcareous skeleton. Meckel considered this view as very improbable, and the description we have given does not tend to corroborate it. We must confess ourselves unable to offer more than mere conjecture as to the use of this singular structure. If the fluid contained in the feet and their vessels be sea-water (either pure, or with an admixture of organic particles), which is probable from its chemical composition, may it not be introduced, and perhaps again discharged, through the pores of the disk and the calcareous tube, the porous disk serving as a sort of filter to exclude impurities?' (*Cyclopædia of Anat. and Physiol.*)

Generative System.—The generation of the Stelliridians appears to be monœcious, of that nature which Professor Owen terms *Cryptandrous Hermaphroditism.* Ovaries are, as far as we are aware, the only organs relating to the generative functions hitherto discovered; but Fabricius, in his *Fauna Groenlandica*, would seem to affirm that two individuals are necessary for the propagation of the species, and states that the coition takes place in the month of May—'congreditur oribus arctè connexis, altera supina.' The ovaries, which appear to vary in number in different species, form, in general, an oblong cluster of tubes branching from a single stem, by which the whole is attached, and ending in circular dilated vesicles. In some species, *Asterias aurantiaca*, for instance, the tubes form numerous bundles (about 20), each of which is distinctly attached, so that they are not all connected by a single stem. In the museum of the College of Surgeons (London), No. 2236 is a portion of a star-fish (*Asterias rubens*, Lam.) prepared to show the ovaria, ten in number, attached on each side of the base of each ray, near the angle of divergence; the ova are not developed in this specimen. No. 2237 exhibits an *Asterias papposa*, Lam., with the anterior parietes of one ray, and the posterior parietes of another ray, dissected off, showing the ovaria with the ova at the commencement of their development. The ovaria are two in number in each ray, as in the preceding species, and are similarly attached on each side of the base of the ray, where they may be distinguished from the digestive and locomotive cæca by their greater opacity and granular structure. No. 2238 is the same species with the posterior parietes of the central disk removed, showing the commencement of the digestive cæca and the ovaries. No. 2239 is a portion of one of the rays of *Comatula solaris*, Lam., showing the ovarian receptacles occupying the inner side of each of the pinnæ, or articulate processes sent off from the rays. Three of the receptacles are laid open to expose the contained ova. (*Catalogue, Physiol. Series.*)

M. Sars states that the young of *Asterias Sanguinolenta* immediately after birth have a depressed and rounded body with four very short club-shaped appendages or arms at their anterior extremity, as above stated. When they are a little more developed, papillæ disposed in five radiating rows on the upper surface may be distinguished. At the expiration of twelve days, the five rays of the body, which up to that time had been rounded, begin to increase; and at the conclusion of eight days more, the two ranges of feet or tentacula are developed under each ray, and assist in the locomotion of the animal by alternate elongation and contraction, and performing the office of suckers.

Skeleton and Dermal Envelopement.—The integuments of a star-fish are—1, a leather-like tough membrane in which portions of calcareous matter, which may be termed the skeleton of the animal, are imbedded; 2, an external membrane of a softer texture; 3, certain appendages. 'The calcareous pieces,' writes Dr. Sharpey, *loc. cit.*, 'form inferiorly a ring round the mouth and a series of transverse segments placed in succession along the floor of each ray. The first of these segments is connected with the ring; they decrease in size as they approach the point or distal end of the ray, and openings are left between them for the passage of the feet. In the *Asterias rubens*, which has five rays, the central ring consists of ten larger and five smaller pieces, the former disposed in pairs opposite the commencement of the rays, the latter corresponding to the angles between the rays. The segments of the rays are symmetrical; in the species mentioned they consist of two oblong pieces united in the median line, and two smaller ones placed laterally. On the sides of the ray the calcareous substance is disposed, as it were, in ribs; these rise from the floor at first nearly parallel with each other, and are connected by cross bars, but on approaching the upper part or roof of the ray they cross in all directions and form an irregular network, the intervals of which are occupied by softer integument. The ribs and bars are made up of small pieces joined by plane but oblique surfaces, a mode of construction calculated to admit of their being lengthened and shortened upon one another, and thus to allow the cavity they surround being dilated and contracted. A broad calcareous disk is situated on the upper surface of the body, in the angle between two of the rays, which is connected internally with the sand-canal. The calcareous pieces are of a homogeneous structure, without cells or fibres; they consist, according to Hatchett's analysis, of carbonate of lime, with a smaller proportion of phosphate of lime. The coriaceous membrane which connects the pieces of the skeleton is made up of white glistening fibres. It is contractile and irritable, for it slowly shrinks on being scratched with the point of a knife, or when it is cut through. The external membrane is much thinner and softer than that just described; in various parts it is coloured, or in these parts there is a coloured layer underneath it. The appendages or processes on the surface

of the body are of three kinds. First, calcareous spines; these are found over the whole surface, except the grooves for the feet. They are attached by a moveable joint at their base to the calcareous pieces of the skin, and are invested by the external soft membrane nearly as far as their point. Those on the upper surface are solitary, short, and for the most part club shaped, their broader summit being marked with radiating points; whence they were named stelliform processes by Tiedemann. On each side of the groove for the feet, the spines are thickly set; these in *Asterias rubens* have three rows, in the middle and innermost of which they are placed three deep. On this part of the surface they are also longer and pointed. The spines are slowly moved at the will of the animal. The appendages of the second kind are of a very singular nature; they have the appearance of pincers of crab's claws in miniature, and were described by Müller as parasitical animals under the name of *Pedicellaria*. Monro gave the name of antennæ to analogous organs which are found on the sea-urchin. They probably do not exist in all species, for Tiedemann makes no mention of them in his description of *A. aurantiaca*. In *A. rubens* they cover the surface generally, and form dense groups round the spines. Each consists of a soft stem, bearing on its summit, or (when branched) at the point of each branch, a sort of forceps of calcareous matter not unlike a crab's claw, except that the two blades are equal and similar. When the point of a fine needle is introduced between the blades, which are for the most part open in a fresh and vigorous specimen, they instantly close and grasp it with considerable force. The particular use of these prehensile organs is not apparent; their stem, it may be remarked, is quite impervious. The third sort of appendage consists of those which are named the respiratory tubes.' In the other Stellridians the same general construction of the skeleton may be observed; but the modifications differ with the forms. In some it consists of hundreds of pieces disposed in various patterns, and fitting with the most minute accuracy. In some these pieces are soldered together, as in the calcareous central purse from which the arms of the *Ophiuræ* radiate; and in others they are united by ligaments, as in the rays of these *Ophiuræ*, the *Gorgonocephali*, and the *Encrinites*.

Voluntary dismemberment; and restoration of lost or injured parts.—The sudden and voluntary act of dismemberment by which many of the Stellridians will save their central disk at the expense of their rays or arms must have struck those who have observed these animals in their native seas, as well as the length of time during which the severed parts still continue to be endowed with motion. This power of dismemberment seems to be carried to its fullest extent in *Ophiocoma* and *Luidia*, and we refer our readers to Mr. Forbes's account of the voluntary breaking up of these genera, especially the latter, in his highly interesting *History of British Star-fishes*, &c. above alluded to.

With regard to the power of restoration, few collectors have not come into possession of a specimen with a budding or growing ray occupying the place of a lost one. Such a case is figured in the article ENCRINITES, vol. ix., p. 390. Jussieu, Guettard, and Gerard de Villars brought to Reaumur specimens of star-fish with four large rays and a small one still growing; they found others, he tells us, with only three large rays and two very small ones; and others with two large rays and three very small, and, as it seemed, very young ones. More than once they met with a large ray, from which four young rays had begun to sprout. Reaumur speaks of the fact as being well known to the fishermen, and in allusion to certain experiments which Jussieu and Guettard had been carrying on, he remarks that the portions into which they had divided the animals appeared to go on well, the wounds healed and consolidated; but he adds, that those who made the experiment were obliged to limit their stay on the coast to about fifteen days; too short a period, he observes, to trace the progress of a reproduction which apparently requires several months, or perhaps even more than a year for its completion.

Systematic Arrangement.

Link, in his volume *De Stellis Marinis* (fol., Leipzig), arranges and figures a considerable number of species, in the method of which the outline is here given.

Section I.

De Stellis fissis.

Class 1.

Oligactis (Star-fishes with fewer than five rays)

Genera, *Trisactis*, *Tetractis*.

Class 2.

Pentactinodos (Quinquefid star-fishes).

Genera, *Pentagonaster*, *Pentaceros*, *Astropecten*, *Palmipes*, *Stella coriacea*, *Sol marinus*, *Pentacdylosaster*.

Class 3.

Polyactinodos (Multifid star-fishes).

Genera, *Hexactis*, *Heptactis*, *Octactis*, *Enneactis*, *Decactis*, *Dodecactis*, *Triscaidecactis*.

Section II.

De Stellis Integris.

Class 1. Stellarum vermiformium.

Genera, *Stella lumbricalis*, *Stella scolopendroides*.

Class 2. Stellarum crinitorum.

Genera, *Decacnemos*, *Triscaidecacnemos*, *Caput Medusæ*.

Class 3. Astrophyton.

Genera, *Arachnoïdes*, *Astrophyton costosum*, *Astrophyton scutatum*.

Linnæus divided his genus *Asterias* into the following sections:—

1. *Integræ*.

Example, *Asterias Luna*, the only species.

2. *Stellatæ*.

This section contained nine species. Example, *Asterias papposa*.

3. *Radiatæ*.

Containing six species. Examples, *Asterias Ophiura*, *Ast. Caput Medusæ*, &c.

Position of the genus between *Medusa* and *Echinus*.

Gmelin arranged the genus in three sections also, retaining the names of Linnæus for the two last; but altering that of the first, under which he includes four species, to *Lunatæ*.

Position of the genus, between *Physsophora* and *Echinus*.

Lamarck, who, according to M. de Blainville, 'a suivi à peu prês les erremens de Link dans la distribution systematique des Stellérides,' arranged them as the first section or family of the *Echinodermatous Radiata*, and separated them into the genera *Comatula*, *Euryale*, *Ophiura*, and *Asterias*.

The number of recent species of *Comatula* (*Alecto*, Leach; *Antedon*, From.) recorded in the last edition of Lamarck is ine. From these Agassiz separates *Comatula multiradiata* for the type of his genus *Comaster*. The same author considers the *Ganymeda* of Gray to be the isolated disk of some species of *Comatula*.

We must here notice *Holopus*, a new genus of the Crinoidean family [ENCRINITES] characterised by M. d'Orbigny from the stony skeleton (squelette pierreux) of a species fished up alive at Martinique and brought home by M. Rang, and named by M. d'Orbigny *Holopus Rangii*.

Generic Character.—Animal fixed to the ground by a root taking the form of the solid bodies upon which it attaches itself. From this root or base springs a foot or entire body, which is short, thick, and hollow, containing the viscera, and opening in a mouth, which fulfils at the same time the functions of an anus placed in the bottom of an irregular cavity formed by the reunion of dichotomous, thick stony arms, convex externally, hollowed into gutters within, divided into numerous articulations, and furnished alternately along their length with small conical ramules, which are strongly compressed. (D'Orb.)

Upon this M. Dujardin remarks that the author, having seen no more than the stony skeleton, has been only able to conjecture the position and structure of the viscera; and that analogy would lead to the supposition that there is a distinct anus, as in *Comatula*. The individual described was about three inches (French) in height.

The genus *Euryale* (*Astrophyton*, Link; *Gorgonocephalus*, Leach; OPHIURA, vol. xvi., p. 450) consists of six species, from which Agassiz separates such species as *Euryale palmifera* [OPHIURA, loc. cit.] under the generic name of *Tricaster*.

Ophiura is divided by Lamarck into two distinct sections: 1st, Those species which have the rays rounded or convex on the back. 2nd, Those species which have the rays flattened on the back, *i.e.* above as well as below. Then comes a crowd of species under the title of 'Espèces que je n'ai point vues.'

We shall presently see that M. de Blainville divides the *Ophiuræ* according to the length and disposition of the spines, without regard to the cylindrical or flattened character of the rays employed by Lamarck.

Agassiz divides the *Ophiuræ* into five sections:—

1. *Ophiura.*

Those species which have the disk very much depressed, the rays simple, scaly, and furnished with very short spines, and embracing or close down upon the rays.

Example, *Ophiura texturata, lacertosa,* Lam.

2. *Ophiocoma.*

Those species which differ from the preceding by having very long and moveable spines upon the rays.

Example, *Ophiura squamata, echinata,* Lam.

3. *Ophiurella (fossil only).*

Those species whose disk is hardly distinct.

Examples, *Ophiura carinata,* Münst.; *Egertoni,* Brod. (see post, p. 18).

4. *Acroura* (fossil only).

Differing only from *Ophiura* in having spines on the sides of the rays instead of scales, while the rays themselves are very slender.

Examples, *Ophiura prisca,* Münst., *Acroura Agassiz,* Münst.

5. *Aspidura* (fossil only).

Having the upper surface of the disk covered by a star of ten plates, whilst the rays, which are proportionally stout, are surrounded by imbricated scales. (*Ophiura loricata,* Goldf.)

Asterias is arranged by Lamarck under the following divisions:—

1.

Those species which have the body scutellated. These are numerous, and comprise the genera *Scutaster, Plataster, Palmaster,* and *Solaster* of De Blainville.

2.

Those which have the body radiated, consisting of numerous species also, and comprising the genera *Solaster* and *Pentaster* of De Blainville.

The *Stellerideæ,* in Lamarck's arrangement, are immediately followed by the *Echinidæ.*

Cuvier makes the *Echinodermes* the first class of zoophytes, and the *Pedicellés* the first order of that class, observing that Linnæus established three genera of them (meaning apparently the three divisions above stated), which are very natural but numerous enough, and comprise species sufficiently varied to be considered as three families.

Cuvier divides the species into—

1st. *Les Astéries* (*Asterias,* Linn.), commonly called *sea-stars.* He recognises some of the genera of Leach and Lamarck, and observes that the *Encrinites* (*Encrinus,* Guettard) ought to be placed near the *Comatulæ.*

The *Oursins* (*Echinus,* Linn.) immediately follow the sea-stars.

M. de Blainville divides the Stelliridians into three families:—1, Those with a stelliform body; 2, those with a disciform body; 3, those with a cupuliform body.

1. *Asteridians.*

Genus *Asterias,* comprising the following divisions or sub-genera:—

A.

Species whose body is pentagonal, and but little or not at all lobated on its circumference; the angles being fissured (*Les Oreillers*).

Example, *Asterias Luna.*

B.

Pentagonal species: delicate, and, as it were, membranous (*Les Palmastéries—Palmipes* of Link).

C.

Quinquelobated species, which are not articulated on the circumference.

Example, *Asterias minuta,* Linn. (*Pentaceros,* Link; *Asterina,* Nardo.)

D.

Pentagonal species more or less lobated and articulated at their circumference (*Les Scutastéries,* or *Platastéries*).

Example, *Asterias tessellata.* [ASTERIAS.]

M. de Blainville remarks that the species of this section, many of which exist in the European seas, do not appear to him to have been examined by zoologists with sufficient accuracy; and he thinks that many species have been confounded under the same name.

E.

Species deeply divided into five rays (*Pentastéries*).

*

Triangular, depressed, and articulated on the edges (*Astropecten,* Link: *Crenaster,* Lhuyd).

Example, *Asterias aurantiaca,* Lam.

* *

Triangular, rather short, and rounded above.

Example, *Asterias rubens,* Lam. (*Uraster,* Ag.)

* * *

Rays long, strait, and often narrowed at their origin.

Examples, *Asterias variolata, Asterias* ? *unifera,* Lam.

De Blainville remarks that the species which enter into this section are numerous, but that their distinction is not yet sufficiently established. He is certain, for example, that four species have been confounded under the name of the Fringed Star (*Astérie frangée*). On the other hand he thinks that those of the last section may have been too greatly multiplied.

F.

Species which are divided into a greater number of rays than five or six. [SOLASTERIES.]

Examples, *Asterias tenuispina; Ast. endeca; Ast. papposa.*

II. *Asterophidians.*

Genera, *Ophiura, Euryale.*

Ophiura

A.

Species the spines of whose rays are very short, and applied upon the latter.

Example *Ophiura texturata,* Lam.

B.

Species the spines of whose rays are long, and not applied upon the latter.

Example, *Ophiura squamata,* Lam. [OPHIURA.]

Euryale.

A.

Species whose rays dichotomize but little, and far from the root.

Example, *Euryale palmifera,* Lam.

B

Species whose rays divide and dichotomize from the base.

Example, *Euryale scutata* [OPHIURA.]

III.

Asterencrinidians

1.

Free *Asterencrinidians.* Example, COMATULA.

2.

Fixed Asterencrinidians.

Genera, *Encrinus: Phytocrinus**: *Pentacrinus; Apiocrinites: Poteriocrinites: Agathocrinites: Actinocrinites: Rhodocrinites: Platycrinites; Caryocrinites; Marsupites: Pentremites.* [ENCRINITES.]

Agassiz also divides the Stelliridians into three families or principal sections, but he gives them different names.

1st. *Asterians,* consisting of those species which have for their digestive organ a single orifice surrounded by suckers, but deprived of teeth; a madreporiform tubercle on the back between the two posterior rays, and deep furrows occupied by many rows of pedicles, going from the mouth to the extremity of the arms.

2nd. *Ophiurians,* comprising those whose body forms a flattened † and distinct disk, to which are annexed more or less elongated or even ramified rays, deprived of furrows on their lower surface.

3rd. The *Crinoidians,* having two separate, but closely approximated orifices to the intestinal canal; and being for the most part fixed by the dorsal surface, by means of an articulated pedicle.

Before we enumerate the genera into which this zoologist divides *Asterias,* we must notice the division of M. Nardo, who had previously proposed the following:—*Stellonia* (*Ast. aranciaca—Ast. calcitrapa*); *Stellonia* (*Ast. rubens—Ast. glacialis*); *Asterina* (*Ast. exigua—Ast. minuta*); *Anseropoda* (*Ast. membranacea—Ast. rosacea*); *Linckia* (*Ast. lævigata—Ast. variolosa*).

The following is the division of Agassiz:—

1. *Asterias* (*Astropecten,* Link; *Crenaster,* Lhuyd; *Pentaster,* Bl.; *Stellaria,* Nardo).

2. *Cœlaster,* Ag., differing from the preceding in having the interior cavity circumscribed by plates disposed like those of the *Echini,* at the summit of which may be perceived a star with ambulacra. A genus approaching the

* N. B. This character must be received with great caution; the disk of those *Ophiuræ* known to us is plumped out, so to speak, when they are alive; though in the dead and dried specimen it is flat.

* A young *Comatula.* † See note in opposite column.

Crinoïdians in its organization, whilst its general form is that of the true star-fishes. Example, only one species, and that fossil, *C. Conltoni*, Ag.

3. *Goniaster*, Ag. (*Scutaster* or *Peltaster*, Bl.) Examples, *Ast. tessellata*, Lam.—*Ast. equestris*, Lam.

4. *Ophidiaster*, Ag. Example, *Ast. ophidiana*, Lam.

5. *Linckia*, Nardo. Example, *Ast. variolata*, Lam.

6. *Stellonia*, Nardo (*Pentaster* in part and *Solaster* in part Bl.) Examples, *Ast. rubens*: *Ast. glacialis*: *Ast. endeca*: *Ast. papposa*: *Ast. Helianthus*, &c.

7. *Asterina*, Nardo (*Asterias*, sect. C., Bl., *Pentagonaster*, Link). Example, *Ast. minuta*.

8. *Palmipes*, Link (*Palmaster*, Bl., *Asteropoda*, Nardo). Example, *Ast. membranacea*.

9. *Culcita*, Ag. (*Oreaster*, Bl.) Example, *Ast. discoidea*.

Mr. G. R. Gray makes the *Hypostoma* the second class of the first section (*Echinodermata*) of his sub-kingdom *Centronia*.

The *Hypostomata* consist of two orders:—1. *Asteroida*; 2. *Ophiuroida*.

Asteroida.

Fam. 1. *Asteriadæ*. Genera, *Asterias*; *Heliaster*; *Tonia*.

Fam. 2. *Astropectinidæ*. Genera, *Nauricia*: *Astropecten*: *Luidia*, *Pentalaster*; *Solaster*: *Polyaster*: *Henricia*.

Fam. 3. *Pentacerotidæ*. Genera, *Culcita*: *Pentaceros*; *Stellaster*, *Hippaster*; *Calliaster*; *Goniaster*; *Echinaster*: *Gymnasteria*: *Dactylosaster*; *Stelloma*; *Cribrella*; *Linckia*.

Fam. 4. *Asterinidæ*. Genera, *Palmipes*, *Asterina*.

Ophiuroida.

Fam. 1. *Ophiuridæ*. Genera, *Ophiocoma*; *Ophiura*: *Rosula*, *Aspidura*: *Ophiurella*; *Anoura*.

Fam. 2. *Euryalidæ*. Genera. *Astrophyton*: *Euryale*: *Nebulia*: *Trichaster*.

The third class is named *Blasteroida*: and consists of one family—*Pentremitidæ*, comprising the genera *Pentremites* and *Orbitremites*.

The fourth class is named *Sphæronoidea*, and comprises the genera *Sphæronites*; *Hemicosmites*, and *Cryptocrinites*.

The fifth class, *Crinoidea*, is divided into four families;

1. *Pentacrinitidæ*. Genera, *Comatula*; *Pentacrinites*, &c.

2. *Apiocrinitidæ*. Genera, *Apiocrinites*. *Holopus*, &c.

3. *Cyathocrinitidæ*. Genera, *Cyathocrinites*: *Marsupites*.

4. *Asterocomidæ*. Genus, *Asterocoma*. (*Cat. Brit. Mus.*, 1840.)

Early in the same year, Müller of Berlin read his paper on the genera of star-fishes to the Berlin Academy, in which the anus or anal pore is employed as characteristic of family distinction. This aperture is described as present in all star-fishes, excepting *Asterias* proper and *Hemicnemis*, which, according to Mr. Forbes, seems to be identical with his previously established *Luidia*. 'His genus *Crossaster* also,' says Mr. Forbes, 'is my *Solaster*, published a year before. Several generic names, previously adopted by Agassiz and Nardo, are wantonly changed; thus *Craster* is turned into *Asteracanthion*, and *Palmipes* into *Asteriscus*, with which he unites *Asterina*. In this paper Müller maintains that one of the five intermediate inferior plates of the *Ophiuridæ* bears a madreporiform tubercle, or rather corresponds to that body, a view which I am not inclined to adopt.'

With regard to *Solaster*, we have seen how long ago *Solastère* was used by De Blainville; but the practice of wantonly changing names is productive of so much confusion that it cannot be too strongly reprobated. Mr. Forbes admits, as all indeed must, that the generic characters in Müller's papers are excellently drawn up; and no difference of opinion can exist as to the great general value of the memoir.

Of Mr. Gray's arrangement Mr. Forbes says, 'The other memoir to which I must allude is one by Mr. Gray on the Starfishes, wherein he calls the class *Hypostoma*, and defines somewhat ambiguously, published simultaneously with my two first numbers,* in the *Annals of Natural History*. I am afraid I must censure Mr. Gray for changing names still more than Müller, and with less reason. It is a pity zoologists do not take a lesson from their fellow-labourers in the field of nature, the botanists, in this respect. Mr. Gray has increased the confusion by giving fragments of descriptions instead of genuine and specific characters, probably from carrying too far a laudable desire for brevity. His essay deserves praise however for recording many new foreign habitats of the beautiful animals he catalogues.'

* October and November, 1840.

In the same work* Mr. Forbes has arranged the *Echinodermata* in six orders, the three first of which are conversant with the Stelleridans:—

'I. *Pinnigrada*. *Crinoidea*.—First appearance of cirrhi, springing from brachial membranes, which, with the true arms, form the organs of motion.

'II. *Spinigrada*. *Ophiuridæ*.—Disappearance of brachial membranes, cirrhi as before: true arms clothed with spines for motion.

'III. *Cirrhigradæ*. *Asteriadæ*.—Arms disappear; body more or less lobed, and lobes channelled beneath for cirrhi, which act as suckers, and are the organs of motion.'

He looks upon the *Echinodermata* and *Arachnodermata* as two parallel groups, and holds it as a law that the divisions of parallel groups should be based on a common principle. (Introduction, p. xiv.)

Fossil Stelleridans.

The number of fossil species of Comatula given in the last edition of Lamarck is five, including *Comatula Wagneri*, Münst., which is marked with a ? All these are from the lithographic slate of Solenhofen, and all but the last are figured by Goldfuss (*Petref.*); but Agassiz considers the species published by Goldfuss as belonging to different genera. Thus, on *Comatula pectinata*, Goldf., he establishes the genus *Pterocoma*, characterized by its pinnated rays, which are so developed and bifurcated that the disk would seem to be null: whilst he refers the three other species, *Comatulæ tenella*, *pectinata*, and *filiformis* to the genus *Saccoma*, which has the disk in the form of a rounded pouch, on the border of which are articulated five slender rays, simply bifurcated up towards their base and pinnated. The same zoologist views the *Glenotremites paradoxus* of Goldfuss, a fossil from the chalk, as the isolated disk of a species of *Comatula*.

For the fossil Encrinites in general, the reader is referred to that article; but we must here advert to the genera *Hypanthocrinites* and *Dimerocrinites*. These Crinoidean genera are established and described by Professor Phillips in Murchison's *Silurian System*, where they are beautifully figured, with other Encrinites, in plates 17 and 18. Both genera are from the Wenlock limestone. Mr. Murchison states that columns and plates of *Crinoidea* occur in all the Silurian formations, from the Upper Ludlow Rock to the base of the Llandeilo flags, and also in the underlying Cambrian Rocks; but he adds that clearly determinable species have as yet been found in the Wenlock limestone only.

M. Hermann von Meyer has lately characterised two new genera of *Encrinites*, viz. *Isocrinus* and *Chelocrinus*.

The last edition of Lamarck records eight fossil species of *Ophiura*, including *Ophiurella*, Ag. (*Ophiura carinata*, Münst.; *Oph. speciosa*, Münst.; *Oph. Milleri*, Phil.; and *Oph. Egertoni*, Brod.): *Acroura*, Ag. (*Oph. prisca*, Münst.); and *Aspidura*, Ag. (*Oph. loricata*, Goldf.). Of these, *Ophiuræ speciosa* and *carinata* are from the lithographic slate of Solenhofen; *O. prisca*, from the muschelkalk of Baireuth: *O. loricata*, from the muschelkalk of Würtemberg, *O. Egertoni*, from the lias at Lyme Regis; *O. Milleri*, from the Yorkshire lias; a nameless species from the same locality (Williamson, *Mag. of Nat. Hist.*, 1836); and *O. Agassiz*, from the muschelkalk.

Thirteen species of fossil *Asterias* are given in the last edition of Lamarck from the lias of Coburg and Bamberg, the lias and muschelkalk of Würtemberg, the upper arenaceous beds of the Westphalian Jurassic formation; the Jurassic limestone of Würtemberg and Baireuth; siliceous from the upper beds of the Jurassic limestone of Baireuth; in the Jurassic limestone of Baireuth; the lower oolite, and the Yorkshire lias. Of these, *Asterias tabulata*, Goldf., from the upper argillaceous beds of the Jurassic limestone of Baireuth; *Ast. scutata*, Goldf., siliceous from the upper beds of the same Jurassic limestone; and *Ast. stellifera*, Gold., from that limestone, are only established

* 'History of British Star-fishes,' &c., 8vo., London, 1841.

† See the article, in which this term—De Blainville writes it *Cirrhigrada*—is employed for the order (the 2nd) of *Arachnodermata*, comprising the genera *Velella*, *Rataria*, and *Porpita*.

on detached osseous pieces, and Agassiz suspects that they are the *calices* of unknown Crinoidians

Dr. Mantell notes two species of *Pentagonaster*, *Semilunatus* being one, in the chalk formation at Lewes.

Mr. Gray has lately established two fossil genera of Star-fishes—*Comptonia*, from the Whetstone pits in the green sand of Blackdown; and *Fromia*, comprehending the tessellated Star fishes found in the chalk.

M. Dujardin observes that M. Desmoulins has described (*Act. Soc. Linn. Bord.*, t. v., 1832), under the names of *Asterias portoïdes*, *A. lævis*, and *A. Adriatica*, the insulated small bones (osselets) of star-fishes (*Asterias*) coming from the tertiary formation; and that the same author gives the names of *A. stratifera*, *A. chilopora*, and *A. punctulata* to other *osselets* of *Asterias* found in the chalk formation; but M. Dujardin observes that the characters could only be taken from the very variable form of these osselets, and the more or less smooth, or more or less punctated and granulated, state of their external surface, and consequently they do not appear to M. Dujardin to possess sufficient value. In truth, he adds, as much might be said of many of the species established by Goldfuss, and also of two established by Agassiz under the names of *Goniaster porosus* and *Gon. Couloni*, on some osseous pieces of *Asterias* found in the chalk formation. He adds that it is at least permissible to think that many of the objects studied and classed by MM. Desmoulins and Agassiz ought to be referred to the *Asterias quinqueloba* of Goldfuss, which is also found in the chalk.

STELLI'NI. [PADOVA (Town).]

STEM, in Botany, is that part of the plant which seeks the light and developes itself in the air, forming its ascending axis, and grows in an opposite direction to the root or descending axis. Although some plants are said to be without stems or roots, this cannot be absolutely true, as all plants develop themselves in two directions, upwards and downwards; the one growth forming the stem, the other the root.

The stem, or ascending axis, is composed of fibrous, spiral, and cellular tissues, arranged in various ways, mostly assuming a cylindrical form, and having a perpendicular direction, and bearing upon it the various parts of the plant. Its form and direction are however subject to much variation in particular cases. In their internal structure stems present three principal modifications characteristic of the three great natural classes into which the vegetable kingdom is divided, viz. exogens, endogens, and acrogens. The stems of exogens are the most complicated in structure: they possess a central pith, and radiating medullary rays filled up with woody tissue, which is deposited in zones of yearly growth, and the whole is covered with an external bark. [EXOGENS.] The stems of endogens possess no pith or medullary rays or bark, but the same tissues which exist in the exogens are distributed irregularly throughout the mass of the stem. [ENDOGENS.] In their mode of growth they also differ, for whilst the increase of the exogenous stem takes place from the centre towards the circumference, the endogenous stem deposits its tissues from the circumference towards the centre. In acrogens the stem is mostly composed of cellular tissue, and only in a few of the higher orders does it possess a cylindrical form. Of these, the stems of tree-ferns are most conspicuous, which contain, in addition to the cellular tissue, both woody and vascular tissue in their structure. The mode of development of the stem of acrogens is also different from that of the others. 'Instead of its increasing by the deposition of matter originating in the leaves, it appears to be a mere extension of some common vegetating point, which becomes cylindrical and long, when it is capable of being acted upon by the influence of light, as in Ferns, Lycopodiaceæ, &c., which expands irregularly and remains flat and foliaceous in such orders as Hepaticæ and many Algæ, which develops in straggling threads in some of the latter, and which collects these threads into masses of reproductive matter in Fungi.' (Lindley, *Natural System*, p. 395.) Although the character of the stem in the large bulk of the orders will at once point out the class to which they belong, yet there are exceptions, and in many instances the structure of the stem would be no guide to its class. This is particularly seen amongst those orders which grow in damp, marshy, and watery places. Thus *Pilularia*, *Marsilea*, *Isoetes*, and *Salvinia*, amongst acrogens: *Naias*, *Caulinia*, *Zannichella*, *Zostera*, and *Potamogeton* amongst endogens; and *Hippuris*, *Myriophyllum*, *Callitriche*, *Trapa*, and *Ceratophyllum* amongst exogens, have a structure closely resembling each other, from which alone the class to which they belong could not be assigned.

Although the most common direction taken by the stems of exogenous and endogenous plants is vertical, yet a great number of them depart from this course, and on this account, or for some peculiarity of form or function, they have received a variety of distinctions. In some plants the stem or primary ascending axis is never pushed above the surface of the earth, and hence stems thus formed are called *subterraneous*. These stems were mistaken by older botanists for roots, and this error is still frequently committed, but the mode of their growth and their structure will always at once distinguish the subterranean stem from the root. [ROOT.]

A common form of the subterranean stem is the *tuber*, of which a good example is afforded in the potato. The tuber is in reality only the thickened part of a subterranean stem, as may be easily seen on examining a bunch of these in the common potato. The tuber mostly produces at irregular intervals buds which are called eyes, any one of which, being removed by a knife, is capable of existing, and forming, when planted, an independent plant. Tubers frequently contain amylaceous matter, and on this account are nutritive, and used as articles of food.

The *cormus* is another form of subterranean stem. It is only seen in endogenous plants, forming a dilated basis from whence the leaves and flowers spring. It is often mistaken for a bulb, but differs from that organ in being entirely solid. The crocus, the colchicum, and the arum afford examples of this form of the stem.

The *soboles*, or creeping stem, is a form of the subterranean. It runs along horizontally under the surface of the earth, giving off at intervals roots and buds. It is frequently called a creeping root. The best example is the couch or spear grass. It is on account of the facility this kind of stem affords to growth, that this weed is so difficult of eradication. Only a small portion left in the earth will be found sufficient to reproduce the plant, which soon rapidly spreads by means of its creeping stems.

Those stems which appear above the surface of the earth are called *aerial*. Of these the following forms are commonly distinguished:—The *root stock*, or *rhizoma*, is a prostrate hardened stem, scarcely distinguishable from roots, giving off branches or young plants. It is seen in the *Aspidium Filix mas*, *Pteris aquilina*, *Juncus effusus*, *Iris germanica*, *Nymphæa alba*, *Gratiola officinalis*, &c. The *surculus*, or *Sucker*, 'is a branch which proceeds from the neck of a plant beneath the surface, and becomes erect as soon as it emerges from the earth, immediately producing leaves and branches, and subsequently roots from its base.' (Lindley.) This term has been very variously used by botanists, but the above definition expresses its most frequent and legitimate application. Link uses the word *soboles* synonymously with it. The *stolo* is only a modification of the sucker. The *runner* (*sarmentum*, *flagellum*) is a long slender stem, running upon the ground and forming at its extremity roots and a young plant. This is seen in the strawberry. In Orchidaceæ, the leaves and flowers are developed from the apex of an oblong green body which in its structure resembles a tuber, but it is above ground; this form of stem, peculiar to Orchidaceous plants, is called a *pseudo-bulb*.

The stem, being the primary axis of the plant, necessarily supports all the other organs. The first of these which are developed is the leaves, which grow from a point of the stem called the *node*. These nodes are either opposite each other or alternate on the stem, and the space between them is called an *internode*. The internode is composed of tissues which are arranged parallel in a vertical direction; but when a node is formed, the tissues take a horizontal direction, passing into the leaf at an angle with the stem. At this point the tissues are more or less contracted, from the suspended vertical development, and in some plants this is very evident, as in many Lamiaceous plants, the grasses, and the bamboo. The point of union between the leaf and stem is called the *axil*, and at this point is constantly developed a bud. [LEAF-BUD.] Although in all cases this bud does not come to perfection, it is always a consequence of the existence of a leaf. The consequence of the growth of a bud is the formation of a branch (*ramus*). When the branches are numerous, the smaller ones are called *ramuli*,

and a collection of branches forming the head of a forest tree is called a *coma*.

The functions of the stem are to support the various organs of the plant, to serve as a medium for conveying the sap from the roots to every other part, and to become the depository in many plants of their various secretions.

(For farther information see SAP; SECRETIONS, VEGETABLE; ROOT; TISSUES, VEGETABLE.)

STE'MMATOPUS. [SEALS, vol. xxi., p. 164.]

STENCILLING. [PAPER-HANGING.]

STENEOSAURUS. [CROCODILE, vol. viii., p. 168.] Professor Owen, in his *Report on British Fossil Reptiles* to the British Association for the advancement of Science, retains the generic name *Steneosaurus* (proposed by Geoffroy St. Hilaire, for the gavial-like crocodilians with subterminal nostrils, but applied by the latter to species with vertebræ of two distinct systems, and altogether rejected by M. Hermann Von Meyer) for that section of the Geoffroyan genus which includes the species with vertebræ concave at both extremities, as in the genus *Teleosaurus*.

Remains of the genus thus circumscribed occur in the Kimmeridge clay at Shotover, and in the great or middle oolite. [STREPTOSPONDYLUS.]

STENO, NICHOLAS, was born in 1638, at Copenhagen, and there also first studied the medical and other sciences. Bartholin was his preceptor in anatomy, and induced him to pursue it with an ardour which was crowned with eminent success. Having left Copenhagen, Steno studied for three years at Leyden, and for two at Paris, and then travelled through the greater part of Germany and Italy. At Florence, Ferdinand II., grand-duke of Tuscany, appointed him his physician in 1667; and Cosmo III., the next duke, retained him in the same post, and made him tutor to his son. In 1669 Steno renounced the Lutheran faith, in which he had been born and educated, but in which his confidence had been shaken during his residence at Paris by Bossuet, and embraced the Roman Catholic religion. Soon after, Frederic III. of Denmark recalled him, but it was not till Christian V., who was more tolerant of Steno's new faith, succeeded, that he was induced to accept the professorship of anatomy at Copenhagen. He held the appointment for only a short time, and then returned to Florence, where, in 1677, giving up the study of anatomy, he took holy orders, and was consecrated bishop of Heliopolis. Soon after, having been invited to the court of Hanover, the pope made him vicar apostolical of the churches in the north, and in this office he remained, devoting himself zealously to his religious duties till 1679, when a Lutheran prince succeeding to the government of Hanover, he was obliged to quit the country. He retired to Münster, and there and in other parts of Germany he continued sedulously preaching till 1686, when he died at Schwerin in Mecklenburg.

Steno is now known chiefly through the results of his anatomical labours, which, considering the short period occupied in them, were neither few nor unimportant. In his inaugural dissertation, published in 1661, he described accurately the salivary glands and their ducts, and especially that of the parotid gland, which Casserius had regarded as a ligament, and which has since been commonly called Steno's duct, though it had been before his time observed by Gerard Blasius. In another small treatise Steno first described the ducts of the lachrymal gland. His principal work, 'On the Muscles and Glands,' &c., was published in 1664, and contains, among many excellent anatomical descriptions, the first good account of the course of the muscular fibres of the heart, the tongue, and the pharynx, and of the anatomy of the respiratory muscles. It includes also most of his observations on the lymph and lymphatics. In his 'Discourse on the Anatomy of the Brain,' Paris, 1679, Steno speaks of its fibrous structure, and urges the propriety of tracing more carefully than had been hitherto done the course of the nerves into its interior. He wrote also several papers in the 'Acta Hafniensia,' containing some excellent observations on the motion of the heart in living animals, on the nature of the ovaries and the ova of quadrupeds, and on the development of the chick. A brief account of his researches is published in Haller, 'Bibliotheca Anatomica,' tom. i., p. 491.

STENODA'CTYLUS. [GECKO, vol. xi., p. 103.]

STENODERMA, M. Geoffroy's name for a genus of Bats. [CHEIROPTERA, vol. vii., p. 26.]

STENOGRAPHY, or the art of short-writing, is a term compounded of two Greek words, στενός, contracted, and γράφειν, to write. The invention of stenography among the Greeks is generally assigned to Xenophon the historian; but it is said that the art was first practised by Pythagoras, and that the poet Ennius was the first who adopted a system of short writing by which a person was enabled to follow a speaker. It is said, though upon no very certain testimony, that he commenced by employing eleven hundred marks of his own invention, and increased the number as circumstances required.

There are also writers who ascribe the invention of the art to Cicero; and it was certainly practised by him on account both of its brevity and secresy. He reminds (*Ad. Att.*, xiii. 32) his friend Atticus that he wrote (διὰ σημείων) by signs. The art was communicated by Cicero to Tiro, his freedman, who made considerable improvements in it, and is said to have been likewise the first person who applied it to the purpose of taking down public speeches. Eusebius attributes the invention to Tiro. The oration of Cato relative to the Catilinarian conspiracy, was preserved by means of shorthand. We are informed by Plutarch, in his 'Life of Cato' (c. 23), that on the occasion of delivering that speech, 'Cicero dispersed about the senate-house several expert writers whom he had taught to make certain figures, and who did, in little and short strokes, equivalent to words, pen down all he said.' The art was subsequently improved, and stenography became a fashionable accomplishment with the Romans. There is extant a work on the shorthand (*notæ* of the Romans) attributed to Tiro and Seneca, and printed in Gruter's 'Collection of Inscriptions.' Most of the writers of that age allude to the stenographic art in their works. Horace points out its brevity; and Ovid mentions its advantages in point of secresy. It is also commended by Ausonius, Martial, Manilius, and others. [NOTARY.] The Roman shorthand was very different from our own: the abbreviations, in general, appear to have resembled those adopted in ordinary writing, and which frequently occur in antient manuscripts, as well as in early editions of Latin works. A very large collection of MS. abbreviations is printed at the end of Göschen's edition of Gaius, and specimens of antient Roman stenography are given in Lewis's 'Historical Account of Shorthand.' Some passages in the Roman writers, which have been supposed to refer to shorthand, appear to refer to writing in cipher.

The first English treatise on Stenography was published in 1588, by Dr. Timothy Bright, and dedicated to Queen Elizabeth. It was entitled 'Characterie, or the Art of Short, Swift, and Secret Writing;' and consisted exclusively of arbitrary characters, each of which represented a word. Two years afterwards appeared 'The Writing Schoolmaster,' in three parts, by Peter Bale. This author remarks that 'Brachygraphy, or the art of writing as fast as a man speaketh treatably, may in appearance seem difficult, but it is in effect very easy, containing a many commodities under a few principles: the shortness whereof is attained by memory, the swiftness by practice, the sweetness by industry.' The system of Bale, like that of his predecessor Bright, was formed of arbitrary characters, instead of a combination of elementary marks or signs. Both systems were exceedingly crude, and difficult of attainment; requiring, as they did, for their practical application, a remarkable tenacity of memory; but they displayed great ingenuity as first attempts. The earliest effort to form a regular shorthand alphabet appears to have been made by John Willis, who, in 1602, published 'The Art of Stenographie, or Short Writing, by Spelling Characterie.' The work went through numerous editions. The alphabet was formed of the most difficult and complex characters, which were ill adapted for joining, their formation consuming treble the time required for forming the characters in any of the modern systems of moderate celebrity. Willis was followed by a host of imitators, none of whom however effected any material improvement. In 1618 appeared a treatise upon Stenography by Edmond Willis, which was followed in 1630 by that of Witt; in 1630 by that of Dix; and by a great number of others at short intervals; and, obscure as most of them were, they were ushered into the world with the utmost pomposity and eulogy. That of Rich, published in 1654, was praised by Locke. In 1753 was published the system of Mr. Thomas Gurney, which has since been so very extensively practised by various members of his family and others, in the houses of parliament, the courts of law, &c. Mr. Lewis, in his 'History of Shorthand,' observes, that it

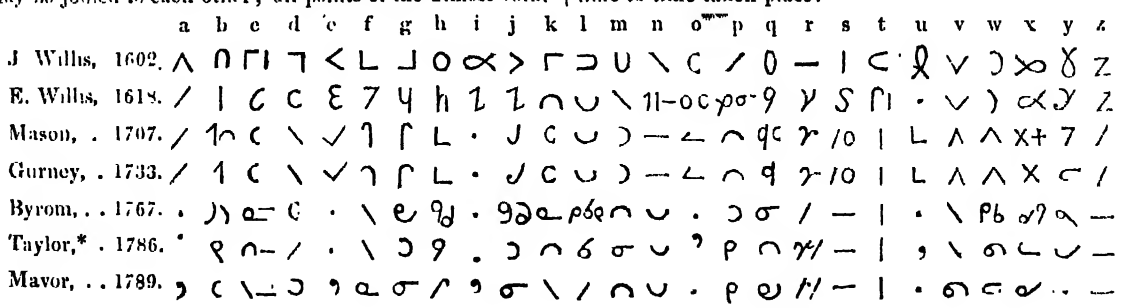
proves how the assiduous student of a bad system may outstrip the negligent pupil of a skilful master; as those by whom Gurney's system has been practised could only have attained eminence as shorthand writers by the exercise of the utmost diligence and perseverance.

Among the more recent systems, that of Dr. Byrom deservedly occupies a very prominent position. He succeeded in forming an alphabet at once simple, precise, and practicable, as well as in rendering the general details of his theory exceedingly clear and intelligible. His system was incomparably superior to any which had preceded it. Indeed Dr. Mavor (himself the author of a deservedly popular treatise on shorthand) observes, in the introduction to his own work, that 'it is above the reach of human ingenuity to exceed his (Dr. Byrom's) general plan, which must for ever be the basis of every future rational system.' Numerous other writers have also borne their testimony to the merit of Dr. Byrom's plan. Although the treatise was completed by the year 1720, it was not published till 1767, after the author's death, who, as he depended for support principally upon private tuition, obtained an act of parliament for the security of his invention. The doctor, in 1749, printed fifty copies of his work for the use of his particular friends. Since its publication it has been edited by several persons. Mr. Thomas Molineux, of Macclesfield, published an edition which he entitled 'An Introduction to Mr. Byrom's Universal English Shorthand.' It was popular for many years; but its circulation has latterly been much diminished owing to the numerous improved systems which have appeared. Many years after the appearance of Mr. Molineux's book, Mr. William Gawtress of Leeds, then one of the proprietors of the 'Leeds Intelligencer,' published a 'Practical Introduction to Shorthand' upon the general principles of Byrom. This unpretending volume is one of the cheapest and most useful manuals of shorthand which ever appeared. It contains many improvements on the original work.

The system next deserving of notice is that of Taylor, which made its appearance in 1786, and is entitled 'An Essay intended to establish a standard for a universal System of Stenography or Shorthand Writing.' This author's system is superior to that of Byrom in several particulars; but principally in a greater brevity and simplicity of the alphabet, and the facility with which the various characters may be joined to each other; all points of the utmost value and importance. Some useful practical improvements upon Taylor's system have been made in Mr. Harding's treatise on the art.

Dr. Mavor's system, though it obtained considerable popularity, is inferior to that of Taylor, on account of its alphabet requiring a greater number of strokes of the pen, and the characters being more difficult of junction. Since the publication of Dr. Mavor's treatise, many others of various degrees of excellence have been published, most of which are utterly destitute of merit. Those of Richardson and Clive are undoubtedly very ingenious, but they are too difficult of attainment to be generally useful. This is more especially the case with reference to the former. The author claimed for it the merit of enabling a person to write more in one hour than in an hour and a half by any other system before published. His principle is totally different from that of any other writer. He accomplishes his object by means of three horizontal and two perpendicular lines, which are placed at about the same distance from each other as the lines of the musical scale. These five lines furnish him (as he observes) with twenty distinct places or situations, which are called by the names of the different letters of his alphabet; and in writing by this system, the initial letter of every word is invariably omitted; the writer placing his pen on the place which represents that initial letter, from thence proceeds to write the second and subsequent letters of the word. The great exactness necessary in the formation and position of the characters must present an insurmountable obstacle to the general adoption of the system. Where however any person can practise it with the requisite facility, it is undoubtedly the best which ever was invented for the purpose of following a speaker. Mr. Clive's system is founded on a much more moderate application of the line principle than that of Richardson.

The foregoing remarks contain a brief history of stenography in this country; but there is scarcely a country in Europe which has not paid more or less attention to its cultivation. Those who desire further information as to the history of the art will find much valuable matter in Mr. Lewis's 'Historical Account of Shorthand.' The following alphabets will in some measure illustrate a portion of the foregoing remarks as to the improvements which have from time to time taken place:—



One experienced shorthand writer at least is now an indispensable auxiliary in the office of every well-conducted journal, and to shorthand writers we owe full reports of the proceedings of parliament, of public meetings, and of the courts of law. The newspaper press has given a powerful stimulus to the cultivation of the art, by affording a respectable livelihood to a numerous body of individuals. In addition to what it has done for the daily and weekly press in particular, shorthand is used for taking down sermons, scientific lectures, and public speeches both in parliament and at the bar. The publication, from the shorthand notes of Sir Henry Cavendish, a member of the 'Unreported Parliament,' as it is termed, which sat from 1768 to 1774, and from which strangers were excluded, is a valuable addition to the political history of the country, which we owe to the art of stenography. The shorthand notes written according to Gurney's system were found amongst the Egerton MSS.

By students of divinity, medicine, law, or others who may wish to preserve the whole or parts of discourses or lectures on scientific or other subjects, shorthand may be studied with great advantage. The art however is not to be acquired without the diligent application of many months, and it also requires considerable manual dexterity, though worthless treatises and travelling teachers of stenography occasionally assert the contrary. The pupil who is deluded in this manner, finding, after he has received the stipulated number of lessons, that he is unable to practise the art, distrusts either his own capabilities for learning, or the assertions of his teacher, and thus abandons the study of the art in despair or disgust.

We shall now give a brief summary of the principles of stenography, according to the system of Taylor, as improved by Harding.

Of the Alphabet.—The vowels are represented by points, a period standing for *a*, *e*, and *i*, and a comma for *o* and *u*. The single consonants of the shorthand alphabet amount only to sixteen, *c* and *z* being rejected as unnecessary, the former having both a hard and a soft sound, similar to *k* and *s*, as in the words 'command' and 'sentence;' *s* is therefore always substituted for *c*, where the letter has a soft sound, and *k* where it has a hard sound: *f* and *v*, being similar in sound, are both represented by the same character. For the same reason, *g* and *j* are represented by one character, as are also *k* and *q*. Characters are also assigned to double consonants, such as *ch*, *sh*, and *th*. These double consonants conduce to both perspicuity and expedition. The vowels are distinguished from each other by their position. For instance, should the period be placed over the top of a consonant, it signifies *a*; if placed against the side, or oppo

* As improved by Harding in the positions of the vowels.

site the centre of the consonant, it becomes *e*; if placed at the bottom, *i*. The personal pronoun *I* is represented by a mark similar to the top part of a note of admiration. The comma is *o* when placed in the same situation as the dot or period for *a*, and *u* when in the same situation as the dot for *e*. Where vowels have been generally omitted, either through the haste of transcribing remarks on any subject, or for expedition in following a speaker, they ought, where such a course is rendered necessary, to be supplied immediately afterwards, while the subject written is fresh in the recollection of the writer. In all words which have neither incipient, terminative, nor long vowels, no middle vowel should be expressed unless some peculiarity may render it expedient or necessary to deviate from this general rule. A word of more than one syllable, having a long vowel in it, must generally have that vowel expressed, because the long vowel being found in that syllable which is most distinctly heard in pronounciation, affords the greatest help in reading; at the same time, however, when a word of more than one syllable consists of several consonants, even the long vowel may be frequently omitted. The various characters of the alphabet represent, when placed by themselves, a number of small words. For example, the *a* or *an* is written by a dot; *the* and also *and* by a comma, the former being written above the line, and the latter below. The consonant b represents the word *be*, *by*, *been*: d, *do*, *did*, *done*: f, *off*, *of*, *if*; g, *God*, *give*, *go*, *good*; h, *have*, *he*; k, *know*, *known*; l, *Lord*, *all*, *will*, and so on throughout the alphabet. For the attainment of practical proficiency in the art, it is necessary that the alphabet should be acquired so perfectly as to be written correctly four times in a minute. It is necessary also in this place to explain that *d* and *r*, which in the alphabet appear to be precisely the same in form, are distinguished by the former, when joined to another consonant, being written downwards, and the latter upwards.

Of Prepositions and Terminations.—Prepositions and terminations are the letters or signs by which the first and last syllables of words are represented. The whole of the single and double consonants of the alphabet are employed in denoting the beginnings or endings of words; in which situations the letters are not joined to the other part of the word, but placed so close as to show their connection and prevent their being mistaken for separate and independent words. The letter *b* represents the prepositions *abs*, *obs*, &c.; and the terminations *ble*, *ible*, *bly*: the letter *d*, the prepositions *de* and *des*, and the terminations *dom*, *end*, *ened*, &c.: the letter *f*, the preposition *for* and the termination *ful*; and the other alphabetical characters are appropriated in a similar manner. Besides the consonants, several arbitrary marks are also used to denote the endings of words. In many cases a preposition and a termination together are all that are necessary to represent a word.

Of Arbitraries.—In the system of Taylor very few arbitraries are employed. They do not exceed twenty in number, and may generally be employed with advantage, which is more than can be said of the arbitraries of several other systems. The experienced shorthand writer may readily, and with much benefit to himself, increase the number of these marks as occasion may require. For instance, the individual who acquires the art of writing shorthand for the purpose of its practical application in a court of law, may readily assign arbitrary marks for such technical terms or lengthy words as are of most frequent recurrence. In the same manner the student of medicine or divinity may also form such characters to suit their own peculiar pursuits; and those persons who practise shorthand for a variety of purposes may in like manner adapt them to the several subjects on which they may have occasion to take notes. The great capabilities of arbitrary characters in these respects have not, we believe, been pointed out as they might have been, either by Mr. Harding or any other author into whose system we have looked.

Of the mode of Spelling.—The great aim of shorthand being to represent words by the fewest simple characters possible, all letters which are not distinctly sounded in any word must be omitted, except in cases where their retention may seem necessary. If words are written as they are pronounced, every silent letter will of course be omitted. In following a speaker however it is necessary that all vowels should be omitted, or otherwise it will be impossible to take more than the substance of his remarks. Where however proper names occur, they should either have the vowels inserted or be written in longhand: the latter method is most advantageous, as the names, when so written, serve as rallying-points to the eye in deciphering shorthand notes. Where the vowels are omitted in general writing, the rule is to write such of the consonants as are sounded in the pronounciation of any word.

Of Miscellaneous Modes of Abbreviation.—As in following a speaker all the vowels require to be omitted, and the consonants only written, so all the small words in a sentence are likewise left out. In some cases however, where the speaker is deliberate and the writer is expert, nearly all the words may be expressed. In the abridgement of sentences of course the writer is guided by his own judgment and the necessities of the case. The different tenses and moods of the verbs are generally expressed in the English language by the help of other verbs, as *shall*, *have*, *had*, *can*, *could*, *may*, *must*, *be*, &c. These being written by their first consonant, may be joined together; but a point should be inserted over the characters, to signify that they are the first letters of words in the sentence. The radical part of a word too may often be sufficient to denote the whole word, as *exp.* for expenses, *pos.* for possible, and so forth. A mode of contraction much used in common writing is to express the first and last consonants of a word, inserting a dash in the middle to show that it is deficient. This plan may be adopted in short-hand writing, or the common letters may be occasionally used. If the characters cannot be distinguished by the plan first pointed out, the termination may be written under the first consonant. The usual abbreviations in longhand can be adopted in shorthand. If a part of a sentence is to be repeated, a line may be drawn under it, and a caret placed where the repetition should be read.

As our object is not to supply a manual by which the art of shorthand may be acquired, but rather to afford some information concerning its leading principles, we have omitted explanations of minor importance.

STENOPS, Illiger's name for a genus of *Prosimii*, his third family of his second order, *Pollicata*, of *Mammalia* including the genera *Loris* and *Nycticebus* of Geoffroy.

Mr. Bennett, in his *Gardens and Menagerie of the Zoological Society*, observes that in an early memoir on the family to which the *Slow-paced Lemur* belongs, M. Geoffroy St. Hilaire divided it for the first time into those minor groups of which it was most obviously composed. But Mr. Bennett remarks that M. Geoffroy has since carried the principle of subdivision to a still greater extent by separating the slow-paced Lemur from the slender Loris, with which he had previously associated it, in order to form from it and some other doubtful species the genus *Nycticebus*. Mr. Bennett cannot perceive any sufficient grounds for thus disuniting two animals so intimately allied to each other, and differing in no more essential characters than the somewhat greater length of the nose and of the limbs in the one than in the other. For this reason Mr. Bennett prefers M. Geoffroy's older arrangement, and proceeds in accordance therewith to describe the Slow-paced Lemur as a species of *Loris*, which he considers to be a well-marked and circumscribed natural genus, differing from the Lemurs of the same author in many highly important characters. Mr. Bennett adds, that it is to be regretted that M. Geoffroy should not have applied the latter name to the species to which it was originally given by Linnæus, and to which alone it is, in Mr. Bennett's opinion, in any degree applicable, the Madagascar animals at present comprehended under it not presenting, he observes, even one of those characters on which Linnæus himself states that his generic name is founded.

'In common with the latter group,' says Mr. Bennett in continuation, 'the genus *Loris* forms part of that division of the Quadrumanous order which is essentially distinguished by an unequal number or irregular disposition of the incisor teeth in the two jaws; terminal nostrils with sinuous openings; and a long subulate or sickle-shaped claw upon the fore-finger of the hinder hands, all the rest of the nails being flat and rounded like those of the greater part of the monkeys and of man. The Loris differs from the other genera of this family in having four incisors in the upper jaw, placed in pairs with a vacant space between, and six in the lower, directed obliquely forwards; canines of moderate size; twelve molars above and ten below; a short rounded head and little or no tail. Sometimes, it would appear, the lateral incisors of the upper jaw, which

are always smaller than the others, are either entirely wanting or so minute as not to be easily seen. But M. Geoffroy was enabled to detect them in the identical specimen which Vosmaer had declared not to possess them: and it is by no means improbable that future investigators may ascertain their existence in the stuffed individuals sent from Java by M. Leschenhault, of which M. Geoffroy has made a new species, principally on account of the supposed absence of these teeth. In addition to these primary characters, the Loris are distinguished by large prominent eyes, placed in front of the head and at no great distance from each other; short ears, scarcely rising through the hair with which they are invested; a rough tongue; nostrils projecting beyond the mouth and surrounded by a naked muzzle; and thumbs widely separated from the fingers, both on the fore and hinder hands.'

The species included in the genus *Lemur* of Linnæus are *Lemur tardigradus, L. Mongoz, L. Macaco, L. Catta*, and *L. volans*. The locality assigned to *L. Mongoz, L. Macaco*, and *L. Catta*, is Madagascar.

Cuvier arranges under the *Makis* (*Lemur*, Linn.), '*Les Loris*, vulg. *Singes paresseux* (*Stenops*, Ill.) between the *Indris* [LICHANOTUS, Ill.] and *Galago* [OTOLICNUS, Ill.]. He states that the Loris have the teeth of the Makis, only that the points of the molars are sharper; a short muzzle (museau court d'un doguin); a slender body; no tail; great approximated eyes; and a rough tongue. Their nourishment, he says, consists of insects, small birds or quadrupeds, sometimes their progression is excessively slow, and their habits nocturnal. Sir Anthony Carlisle, he adds, found at the base of the arteries of the limbs, the same division into small branches as exists in the true sloths. To this part of their organization we shall presently allude more at large. Cuvier remarks, that two species are known, both from the East Indies—'*Le Loris paresseux, ou Le Paresseux de Bengale* (*Lemur tardigradus*, Linn.)' and '*Le Loris grèle* (*Lemur gracilis*);' the latter, he remarks, has the nose more raised by a projection of the intermaxillary bones, and upon this difference of the nose M. Geoffroy has made of the first-named species his genus *Nycticebus* and of the second his genus *Loris*.

M. F. Cuvier assigns the following dentition (that of the Great Galago)—Incisors $\frac{4}{6}$; canines, $\frac{2}{2}$; molars, $\frac{6-6}{5-5}$ = 36—to the small Galago, the Slender Loris, the Cingalese Loris, the Slow-paced Loris or Lemur, and the Dwarf Lemur, with hardly more than very slight exceptions, which are only manifested in the incisors and false molars.

The following are the generic characters of *Loris* and *Nycticebus*, Geoff.:—

Loris: four upper incisors; six lower incisors inclining forwards; head round, eyes very large, limbs very slender, no tail; four mammæ coming from two mammary glands only.* The tibia longer than the femur; ears short and hairy.

Dental Formula:—incisors $\frac{4}{6}$; canines $\frac{1-1}{1-1}$; molars $\frac{6-6}{5-5}$ = 36.

Species.—1, *Loris grèle, Loris gracilis*, Geoff.; *Le Loris*, Buff.; *Le Tardigradus*, Seba. 2, *Loris de Ceylan; Loris Ceylonicus*, Fisch.

The locality assigned to both these species is Ceylon; but, according to M. Lesson, neither Geoffroy, Desmarest, nor F. Cuvier admit the second species, regarding it as a simple variety differing hardly at all from *Loris gracilis*.

Nycticebus. Head round, muzzle short, eyes very large, ears short and hairy, a tail more or less long, extremities strong and robust.

Dental Formula:—Incisors $\frac{2 \text{ or } 4}{6}$; canines $\frac{1-1}{1-1}$; molars $\frac{6-6}{5-5}$; = 34 or 36.

Species, *Nycticebus Bengalensis; N. Javanicus;* and *N. Ceylonicus:* all from the East Indies.

We here adopt Mr. Bennett's view of the subject, and take the *Slender Loris* and the *Slow-paced Loris*, or *Slow-paced Lemur*, both of which are confounded by Linnæus under the name of *Lemur tardigradus*, as examples of the genus *Loris*.

* The glands, though apparently confluent, are actually distinct on each side, and agree in number with the mammæ.

We first notice *Loris gracilis*

Description.—Visage produced and dog-like, forehead high above the nose; ears large, thin, and rounded; body slender and weak; limbs very long and slender: thumb on each foot more distinct, and separate from the toes; on that and the three outmost toes are flat nails; on the interior toe of every foot a crooked claw; no tail: the hair on the body universally short and delicately soft; the colour on the upper part tawny, beneath whitish, space round the eyes dusky; on the head is a dark-shaped spot with the end pointing to the interval between the eyes. Length from the tip of the nose to the anus only eight inches.

Habits, &c.—Pennant, whose description we have given, states that notwithstanding the epithet (tardigradum) given in Seba, who has figured the animal (male and female) in the 35th plate of his first volume, the Slender Lemur is very active, ascending trees most nimbly, and having the actions of an ape. 'If,' says Pennant, 'we credit Seba, the male climbs the trees, and tastes the fruits before it presents them to its mate.' Seba himself observes that the epithet *tardigradum* is misapplied. Others say that it is a melancholy animal, silent and very slow, sleeping in the day and only awaking in the evening, and living on insects, fruits, and eggs.

Loris gracilis.

Loris tardigradus.—The most accurate description known to us is that given by Mr. Bennett, in the work above quoted, and which we here present to our readers in his own words.

'The Slow-paced Lemur is an animal of small size, scarcely equal to that of a cat. The largest individual yet noticed appears to be that seen by Pennant, who states its length at no less than sixteen inches from the nose to the extremity of its back. Its proportions are short and thickset; and the apparent clumsiness of its form is much increased by the manner in which it usually contracts itself into a kind of ball. Its head is broad, flat, and rounded, with a slightly projecting and pointed muzzle, in which the nostrils are perforated laterally. Its eyes are large and perfectly orbicular, and furnished with transverse pupils capable of being entirely closed during the day, and of being very largely dilated at night; their inner canthus is situated so low towards the nose that the motion of the eyelids appears to take place in a diagonal instead of a horizontal direction. The ears are short, round, widely open, but buried in the fur; and the tail is merely a rudiment of a few lines in length. The hinder limbs are considerably longer than the fore. The whole of the body, with the exception of the muzzle and hands, is thickly invested with long close woolly hair of a deep ashy grey with something of a brownish tinge. A deep brown or chestnut band passes along the middle line of the back, and is accompanied on either side by a faint greyish stripe, expanding on the back of the head into a still lighter patch. The dark middle stripe divides on the head into two branches, each of which is again subdivided, the posterior division passing transversely across the forehead and enclosing the ear, the anterior crossing the eye obliquely and extending to the angle of

the mouth. Between the two, above the outer angle of the eye, is a large white spot. Each of the eyes is surrounded by a ring of dusky black, between which a narrow white line passes from the back part of the head to the tip of the nose, which, with the exception of the naked muzzle, is also white. The latter, together with the naked parts of the hands, is of a livid flesh-colour with a tinge of black. On the under surface the fur is of a lighter grey than above.'

There are some parts of the *organization* of this animal that require more particular notice.

Sir Anthony Carlisle injected the arterial system of a *Lemur tardigradus*, and upon tracing the course of the vessels, so as to make a dried preparation, which is now in the Museum of the Royal College of Surgeons in London, he found that an unusual appearance of distribution was exhibited by the large trunks of the subclavian and external iliac arteries. He shows that immediately after the subclavian has penetrated the axilla, it is divided into twenty-three equal-sized cylinders, which surround the principal trunk of the artery, here diminished in size to an inconsiderable vessel. These cylindrical arteries, he observes, accompany each other, and divide with the ulnar and radial branches, being distributed in their route upon the muscles, each of which has one of these cylinders. The other branches, for example the radial and ulnar, proceed like the arteries in general, dispersing themselves upon the skin, the membranes, joints, bones, &c., in an arborescent form. The iliac artery, he tells us, divides upon the margin of the pelvis into upwards of twenty equal-sized cylinders, surrounding the main trunk, as described in the axillary artery: these vessels are also finally distributed as in the upper extremity; the cylinders wholly upon the muscles, and the arborescent branches on all the other parts. The cylindrical arteries, he adds, do not divide into equal-sized cylinders, but are distributed as in the generality of animals.

Sir Anthony concludes by observing that it would be of some importance in physiology to ascertain whether the other slow-moving quadrupeds have any peculiar arrangement of the arteries of those limbs. This solitary fact, he remarks is hardly sufficient for the foundation of any theoretical explanation of the slow movement of these muscles: if however it should be corroborated by similar circumstances in other animals, he thinks that a new light may be thrown upon muscular motion, by tracing a connection between the kind of action produced in a muscle, and the condition of its vascularity or supply of blood.

Mr Baird, in his interesting paper in the *Magazine of Nat. Hist.*, vol. i., 1829, remarks that all the known *Mammalia* close their eyelids in a direction upwards and downwards, and, in general, the upper eyelid is the one possessing the greatest degree of motion. He found however that in his slow-paced Lemur, the eyelids were brought together in a diagonal direction, or outwards and inwards, which gave the animal at the moment of shutting its eyes a most peculiar look. It was the under or outer eyelid that had the greatest degree of motion, the upper or inner one being almost fixed: and he concludes that the *orbicularis oculi* must be very powerful. After the death of the animal, and when Mr. Baird had left this country on a second voyage to India, the eye was dissected by Dr. Knox, who found that the peculiar movement of the eyelids above described did not depend on any peculiar structure, but merely on the greater degree of strength of the orbicularis muscle.

Mr. Baird also observed another peculiarity in the species. 'Beneath the tongue proper,' says he, 'if I may so call it, which is somewhat like that of the cat, though not rough, is another tongue, white-coloured, narrow, and very sharp-pointed, which he projects along with the other one when he eats or drinks, though he has the power of retaining it within his mouth at pleasure.' Mr. Baird however had not been able to see any particular purpose to which he applied it; but he saw him use this double tongue when eating flies, of which he was exceedingly fond, snapping them up most eagerly when presented to him, and catching them himself when they were reposing in the evening upon the walls of the room.

Habits, &c.—Little or nothing certain appears to be known of the habits of the Slow Lemur of Bengal in a state of nature, except as they may be inferred from those which it exhibits in captivity. In this latter state many good observers have narrowly watched it, and have recorded their observations.

Vosmaer received one in June, 1768, and kept it in his chamber. It slept all day to the evening, not waking (it being summer) till half-past eight. It was shut up in an oblong cage, secured with iron bars, and constantly slept sitting on its hinder parts close to the bars, with its head brought forwards between its fore-feet, which were bent against its belly. In this attitude it held on strongly to the wires with its hind feet, and often by one of the anterior feet as well, which induced Vosmaer to think that the animal ordinarily slept in trees attached to the branches. When awakened, it moved very slowly, and always the same from the commencement to the end, dragging itself from bar to bar, grasping one above with its fore-foot or rather hand, and not quitting its hold till it had slowly but very powerfully seized another with one of its anterior feet or hands. The same slowness marked its creeping on the ground, along which it dragged one foot after the other, as if it had been paralytic. In this mode of progression it raised its body but very little, so little, that as it dragged itself forward, the belly was frequently not more than the breadth of a finger from the ground. It was vain to attempt to drive it by putting a stick through the bars; for it would not quit its hold, and if pushed too roughly, its only defence was biting the stick. As the evening approached it awaked by degrees, like one whose sleep is broken after long watching. Its first care was to eat, for the day had been dedicated to repose. After its repast, which it despatched with comparative celerity, the remains of its former meal were evacuated. The fæces were in small pellets like sheep's dung, and the urine had a strong disagreeable odour. The sea-captain who brought it over, stated that it fed on rice boiled very thick, and that it had never been seen to drink.

Vosmaer, impressed with the belief that his animal would not refuse a different sort of food, gave it a leafy lime tree sprig: this it rejected. Fruits, such as pears and cherries, were more to its taste. It willingly ate dry bread and biscuit; but, if dipped in water, would touch neither. When offered water, it smelt it, but drank not. Eggs were favourite diet. 'Il aimoit à la fureur les œufs,' are the words of Vosmaer, who, concluding from its appetite for eggs that it would eat birds, gave it a live sparrow, which it instantly killed with a bite, and ate the whole very greedily. He gave it a live cockchafer, to try whether it would eat insects: it took the offering in its paw, and devoured it completely. Vosmaer afterwards gave it a chaffinch (pinçon), which it ate with much relish, and afterwards slept for the remainder of the day. He often saw it still awake at two hours past midnight; but from half-past six in the morning its sleep was so sound, that its cage might be cleaned without disturbance to its repose. If forcibly awaked during the day in order to teize it, it was vexed, and bit the stick; but with a very slow motion, repeating the cry *ai, ai, ai*, drawing out the *ai* each time into a plaintive, languid, and trembling note, in the same manner as is reported of the American sloths. When it was thus harassed for a long time, and thoroughly roused, it crawled two or three times round its cage, and then slept again.

The specimen observed by Sir William Jones was a male, as Vosmaer's appears to have been; and Sir William thus gracefully describes its habits:—'In his manners he was for the most part gentle, except in the cold season, when his temper seemed wholly changed; and his creator, who made him so sensible of cold, to which he must often have been exposed even in his native forests, gave him, probably for that reason, his thick fur, which we rarely see on animals in these tropical climates: to me, who not only constantly fed him, but bathed him twice a week in water accommodated to the seasons, and whom he clearly distinguished from others, he was at all times grateful: but when I disturbed him in winter, he was usually indignant, and seemed to reproach me with the uneasiness which he felt, though no possible precautions had been omitted to keep him in a proper degree of warmth. At all times he was pleased with being stroked on the head and throat, and frequently suffered me to touch his extremely sharp teeth; but at all times his temper was quick; and when he was unseasonably disturbed, he expressed a little resentment by an obscure murmur, like that of a squirrel, or a greater degree of displeasure by a peevish cry, especially in winter, when he was often as fierce, on being much importuned,

as any beast of the woods.' From half an hour after sunrise to half an hour before sunset he slept without intermission, rolled up like a hedgehog: and, as soon as he awoke, he began to prepare himself for the labours of *his* approaching day, licking and dressing himself like a cat, an operation which the flexibility of his neck and limbs enabled him to perform very completely: he was then ready for a slight breakfast, after which he commonly took a short nap; but when the sun was quite set, he recovered all his vivacity. His ordinary food was the sweet fruit of this country; plantains always, and mangoes during the season; but he refused peaches, and was not fond of mulberries, or even of guaiavas: milk he lapped eagerly, but was contented with plain water. In general he was not voracious, but never appeared satiated with grasshoppers, and passed the whole night, while the hot season lasted, in prowling for them: when a grasshopper, or any insect, alighted within his reach, his eyes, which he fixed on his prey, glowed with uncommon fire; and having drawn himself back, to spring on it with greater force, he seized his victim with both his fore-paws, but held it in one of them while he devoured it. For other purposes, and sometimes even for that of holding his food, he used all his paws, indifferently, as hands, and frequently grasped with one of them the higher part of his ample cage, while his three others were severally engaged at the bottom of it; but the posture of which he seemed fondest was to cling with all four of them to the upper wires, his body being inverted; and in the evening he usually stood erect for many minutes, playing on the wires with his fingers, and rapidly moving his body from side to side, as if he had found the utility of exercise in his unnatural state of confinement. A little before day-break, when my early hours gave me frequent opportunities of observing him, he seemed to solicit my attention; and if I presented my finger to him, he licked or nibbled it with great gentleness, but eagerly took fruit when I offered it, though he seldom ate much at his morning repast: when the *day brought back the night*, his eyes lost their lustre and strength, and he composed himself for a slumber of ten or eleven hours. . . . . My little friend was, upon the whole, very engaging; and when he was found lifeless in the same posture in which he would naturally have slept, I consoled myself with believing that he had died without pain, and lived with as much pleasure as he could have enjoyed in a state of captivity.'

Mr. Baird, in the paper above quoted, gives an account of one of these Loris (*loeris*, a clown, Dutch; name in Ceylon, according to that gentleman). Mr. Baird's specimen was a male, and was obtained at Pulo-Penang (Prince of Wales's Island). When Mr. Baird wrote, he had been in possession of the animal upwards of nine months. Its food consisted of fruit and small animals, such as birds and mice. The plantain was the fruit of which he was the most fond, and was the only food Mr. Baird saw him eat when he first got him into his possession. The necks of fresh-killed fowls formed the major part of its sustenance during the voyage. It was particularly fond of small birds: these, when put into his cage, he killed speedily, and, stripping off the feathers, soon devoured them, eating the bones as well as the flesh. Veal was preferred to all other butcher's meat, and it was fond of eggs; meat boiled, or otherwise cooked, it would not touch. Sugar appeared to be grateful to its palate, and it ate gum-arabic. 'As flesh is not always to be had quite fresh (the only state in which it is acceptable to him), he has for some time past been fed upon bread sopped in water, and sprinkled with sugar; this he eats readily, and seems to relish it much. M. Vosmaer mentions that his animal eat dry biscuit, but refused it if moistened with water; neither would it ever taste water. This is completely at variance with the habits of my animal, for he not only eats moistened bread, but laps water like a cat. When food is presented to him, if hungry, he seizes it with both hands, and, letting go with his right, holds it with his left all the time he is eating. Frequently, when feeding, he grasps the bars in the upper part of his cage with his hind paws and hangs inverted, appearing exceedingly intent upon the food he holds fast in the left hand. He is exceedingly fond of oranges;'—in this the animal resembled a domesticated *Lemur albifrons* once in our possession;—'but when they are at all hard, he seems very much puzzled how to extract the juice. I have, upon such an occasion, seen him lie all length upon his back, in the bottom of his cage, and, grasping the piece of orange with both hands, squeeze the juice into his mouth.' Mr. Baird, after noticing the cry mentioned by Vosmaer and Sir W. Jones, says, 'When the cat annoys him, which she does very frequently by leaping over him, he repeats the cry nearly a dozen times: it is always however expressive of anger. He has also another sort of cry expressive of eagerness to obtain anything: this is much gruffer in sound, not shrill nor loud, but apparently made by forcing the air out of his nostrils. He likes much to be stroked under the chin and throat, and also under the arms, turning his head round to the hand like a cat, and lifting his arm, stretching it out beyond his head. Though not a very sensible animal, he is still evidently capable of feeling kindness and showing resentment. He allows his throat and fore-arms to be stroked, but refuses to let the same liberty be taken with his lower limbs. For some time while in China, a little Chinese dog was his companion, sleeping in the same cage with him; and, with the exception of a few occasional jars, they lived very comfortably together. As the dog grew up however they were separated. A cat, the only animal in the house besides himself, has made many overtures to him, and when he is allowed to get out of his cage, he is followed up and down the room by his feline companion, who evidently wishes to make him her playfellow. Any undue familiarities however on her part are met with an immediate repulse from him; and, one time, when patting him rather incautiously with her foot, he bit her so severely, that she now, though evidently wishing to be on good terms with him, keeps at a safe distance. This same cat has, since this, become more familiar. Though not daring to approach him, she follows him wherever he goes, to his great annoyance, and renders herself an object of his abhorrence. He cries out on her approach, and is sadly tantalised by her playful trick of leaping over him. He seems to be rather a social animal notwithstanding. A large japanned tray attracts a good deal of his attention. Seeing his image reflected in it, he walks before it, and tries to grasp his own image. Finding his efforts ineffectual, he imitates the action of the child, by peeping behind it, with expectation to see the object there. Before a looking-glass he shows the same regard and curiosity.' In most respects, the rest of Mr. Baird's description agrees with those of Vosmaer and Sir W. Jones.

M. d'Obsonville's memoir is very interesting, but offers no differences sufficient to justify the insertion of his account of his specimen at length. The little animal, which enjoyed comparative liberty, being suffered to go at large, appeared to him to be very much attached. He used to caress it after giving it food; and the marks of sensibility upon the part of his favourite were, taking the end of his hand and pressing it to its bosom, fixing, at the same time, its half opened eyes upon his.

One that Pennant saw in London, slept holding fast to the wires of its cage with its claws, as above described, and he states that the inhabitants of Bengal call the animal *Chirmundi Billi*, or *Bashful Billy*. Sir W. Jones says of it, 'The Pandits know little or nothing of the animal: the lower Hindus of this province generally call it Lajjábánar, or the Bashful Ape; and the Mussulmans, retaining the sense of the epithet, give it the absurd appellation of a cat; but it is neither a cat nor bashful; for though a Pandit, who saw my Lemur by day-light, remarked that he was *Lajjálu*, or modest (a word which the Hindus apply to all sensitive plants), yet he only seemed bashful, while in fact he was dimsighted and drowsy; for at night, as you perceive by his figure, he had open eyes, and as much boldness as any of the *Lemures* poetical or Linnean.'

In a state of nature there can be no doubt that its habits are, for the most part, arboreal; and that it takes its prey by night, seizing that which is living, such as small birds, mice, and insects, by surprise, probably whilst they are sleeping; and varying its diet by having recourse to fruits.

Localities.—'As to his country,' says the author last quoted, 'the first of the species that I saw in India was in the district of Tipra, properly Tripura, whither it had been brought, like mine, from the Garrow Mountains; and Dr. Anderson informs me that it is found in the woods on the coast of Coromandel: another has been sent to a member of our society from one of the eastern isles; and though the Loris may be a native of Silán, yet I cannot agree with M. de Buffon that it is the minute, sociable, and docile animal mentioned by Thevenot, which it resembles neither in size nor disposition.'

It has been found in other parts of the peninsula of Hindustan; and in Java, Penang, and Ceylon.

Loris tardigradus.

STE'NOPUS. [SHRIMPS, vol. xxi., p. 425.]

STENORHYNCHUS. [SEALS, vol. xxi., p. 163.]

STEPHANO'MIA. [PHYSOGRADA, vol. xviii., p. 138.]

STE'PHANUS ATHENIENSIS (Στέφανος Ἀθηναῖος), an antient Greek physician, the author of several treatises still extant. Nothing is known of the events of his life, except that (if we may believe the titles of some manuscripts at Vienna) he was a pupil of Theophilus Protospatharius. (Lambec., *Biblioth. Vindob.*, lib. vi., p. 198, 223, 492; lib. vii., p. 352, ed. Kollar.) Neither is it known for certain when he lived, for his having Theophilus for his tutor does not at all help to decide this question, as it is equally difficult to determine the date of the master as of the pupil. G. J. Vossius (*Lib. de Philosoph.*, cap. 13, p. 109, in *Opera*, tom. iii., ed Amst.) and Fabricius (*Biblioth. Gr.*, tom. xii., p. 693) think he is the same as the author who is known by the name of *Stephanus Alexandrinus*, and who dedicated his work *De Chrysopoeia* to the emperor Heraclius (A.D. 610-641); and that he might have been called *Atheniensis* from having been born at Athens, and *Alexandrinus* from having settled at Alexandria. Probably however neither of these great scholars ever saw his works in the original; as Dietz, his editor, notices several words that occur in them, which seem to belong to the eleventh century rather than the seventh (*e.g.* Ψυχία ἄφρατα, *Comment in Hippocr.* '*Prognost.*,' p. 87; τζίμβλοι, *ibid.*, p. 89; λαγωδάτον κοιμᾶσθαι, p. 94; μάγκιπες, p. 146; ἀκατίδες, p. 154; κλοκίον, p. 159). The first of his works that we possess is a Commentary on the '*Prognostics*' of Hippocrates, which was first published by Dietz (who calls him 'inter Hippocratis interpretes sequioris aetatis facile princeps'), in the first volume of his *Scholia in Hippocratem et Galenum*, Regim. Pruss., 1834. There is also a commentary on the 'Aphorisms' which bears his name, and which in fact agrees word for word with that which is commonly attributed to Theophilus. Some extracts from this are inserted in the second volume of Dietz's collection. His commentary on Galen's *Ad Glauconem de Medendi Methodo*, is said by Fabricius and Choulant (*Handb. der Bücherkunde für die Aeltere Medicin*, Leipzig, 1841) to have been first published at Venice in Greek by Aldus, 1536, 8vo.; but Dietz doubts the existence of this edition. He has himself inserted the commentary in the first volume of his collection mentioned above. It had before appeared several times in a Latin translation by Augustinus Gadaldinus, Venet., 1554, 8vo., Lugd., 1555 and 1558, 8vo. Another of his works was published in a Latin translation by Casp. Wolf, with the title *Alphabetum Empiricum, sive Dioscoridis et Stephani Atheniensis de Remediis Expertis Liber, &c.*, Tiguri, 1581, 8vo. The treatise on fevers, sometimes attributed to Stephanus Atheniensis, is in fact by Palladius. [PALLADIUS, vol. xvii., p. 170.]

The work on Alchemy by Stephanus Alexandrinus consists of nine πράξεις, or *Lectures* (see Fabricius, *Biblioth. Gr.*, tom. xii., p. 695), with the title Στεφάνου Ἀλεξανδρέως, Οἰκουμενικοῦ Φιλοσόφου καὶ Διδασκάλου, Μεγάλης καὶ Ἱερᾶς ταύτης Τέχνης περὶ Χρυσοποιίας Πρᾶξις ἐν Θεῷ πρώτη. It was published in Latin, Patav., 1573, 8vo., by Dominic Pizimentus, together with Democritus, Synesius, and other writers on the same subject. The writer was a Christian, and lived (as was before noticed) in the seventh century. Reinesius (ap. Fabric., *Bibl. Gr.*, tom. xii., p. 757) speaks highly of his work, but notices that he falls into the common error of the Eastern and Greek churches of that age respecting the procession of the Holy Ghost. This was one of the works which Dietz was preparing to edit at the time of his death. (See *Schol. in Hippocr. et Gal.*, Praefat., p. xix.)

It may be mentioned that the father of Alexander Trallianus (Alex. Trall., *De Re Med.*, lib. iv., cap. 1, p. 230, ed. Guint.), and a physician of Edessa, sent by Justinian as ambassador to the Persian king (Procop., *De Bello Pers.*, lib. ii., cap. 26) must not be confounded with the two writers noticed in this article, both of whom probably lived much later.

STE'PHANUS BYZANTI'NUS, a Greek grammarian, the author of a geographical dictionary, the earliest probably ever written. Nothing is known of his life, and his age is uncertain; he is placed by Saxius (*Onomasticon*, i., 520) in the latter part of the fifth century. Of his original work nothing but an abridgement made by Hermolaus, another grammarian, who lived in the time of the emperor Justinian, has come down to us, with the exception of a fragment of the letter Δ beginning with Dyme and ending with Dodona, which was first published from the 'Bibliotheca' of Peter Seguier, by Samuel Tennulius, Amstel., 1669, 4to. A comparison of this portion of the original work with its abridgement will show how much valuable matter has been omitted by Hermolaus. Constantine Porphyrogennetus, in his book 'De Administrando Imperio,' c. 23, 24, and in that on the Themata (lib. 2, *Thema* 6, 9, 10, 12), quotes from Stephanus and gives much fuller extracts than are found in the 'Epitome,' and in one instance cites him by name (*Thema* 9, 'De Sicilia;' see 'Excerpta Constantini Peiresciana,' edit. Henr. Valesius, p. 493; and also *Etymolog. Magnum*, voc. Σφήκεια). In the work, as it has come down to us, much of the letter K, from KE to KO, is wanting, which is known to have existed, according to Scaliger, quoted by Fabricius (*Biblioth Graec.*, iii. 51, Hamburg, 1717). The latter part is less full than the earlier; from Patræ to Σ little more than the names of places and their adjectives are given; from this letter onwards the extracts become less meagre. In X and Ω we have what, from the difference in style, may be considered an uncurtailed transcript of the original; the first nine articles of X are abridged in the 'Codex Vratisl.,' like those of the preceding letters, as if the epitomist had desisted suddenly in his undertaking. The difficulty of distinguishing the original material from the possible additions of Hermolaus prevents us from relying with any certainty on several passages in the work which have been thought to refer to Stephanus himself. Under the word Ἀνακτόριον, he or his abridger speaks of Eugenius, a grammarian (according to Suidas) of the time of the emperor Anastasius; in the article Γότθοι occur the words, 'as has been said by me in the Byzantica;' and under Βήτλεμα (Bethlehem) are expressions, which prove the writer of them to have been a Christian. Westermann, in the preface to his edition of Stephanus (Lips., 1839, 8vo.), is inclined to apply these passages to him rather than to Hermolaus, and his reasons are apparently just. In the Burney MS. 50, 11, 254, British Museum, in a volume entitled 'Vitæ, Mores, et Dicta Patrum Sanctorum, Ordine Alphabetico disposita, ex Johannis Moschæ Prato Spirituali aliisque Auctoribus collecta,' is mention of a Stephanus of Byzantium, who is described as one of the scribes or chartularii of Maurianus the General; his great fame is spoken of, and a miraculous scene at his death is described, at which the narrator and Theodosius, bishop of Babylon, are said to have been present. A Count Maurianus lived in the time of the emperor Zeno, A.D. 490 (*Chron. Paschal.*, 261; *Corpus Byzant. Script.*, Venet., 1729); and another was Comes Domesticorum in the time of Honorius (Banduri, *Comment. in Antiq. C. P.*, lib. ii., 477, ibid.), and it is possible that some future discovery may connect the Stephanus mentioned in this passage with the subject of this biography.

Westermann has adopted the title Ethnica (Ἐθνικά), on the authority of Eustathius, instead of that of Περὶ Πόλεων, prefixed to the work by Aldus and others. The editions of Stephanus are, Aldi Manutii, Venet., 1502, fol.; Flo-

rent. ex Juntar. officin., 1521, fol.; Gesner, Basil., 1553 fol; Xylander, Basil., 1568, fol., cum castigat.; Thomas de Pinedo, Amstel., 1678, with a Latin translation and useful commentary, and the fragment published by Tennulius. Luc. Holsten., Lugd. Batav., 1684, with many annotations; Abraham Berkel, Lugd. Batav., 1688, fol. This edition was finished by Gronovius, 1694, who republished the fragment with a triple Latin translation in the 7th vol. of the 'Thesaurus Antiq. Græc.' (See Saxii *Onomas.*, and Fabricius, as cited above; also the edition of the latter, Helmstadt, 1774, for some additional remarks.)

The work of Stephanus contains many interesting particulars relative to history and mythology; it treats of towns, nations, and tribes, giving to each proper name its gentilitial adjective. It does not however appear, as some have supposed, that the chief object of the author was to convey grammatical information, and a title to the work, written at the end of the fragment already mentioned, and quoted as proving this, is not considered genuine. The number of authors cited in the fragment makes us the more regret the loss of so valuable a compilation as the whole work must have been. The notices of cities in the 'Epitome,' particularly of those which struck coins, are very useful in the illustration of the local history and topography of the antient world.

STEPHEN, the first Christian martyr, has been supposed, on no very sufficient grounds, to have been one of the 'seventy-two disciples.' It is more likely that he was an Hellenistic Jew, and one of the large body converted on the day of Pentecost by the preaching of St. Peter. He appears to have been a person of some reputation, and was one of the seven deacons chosen to attend to the temporal affairs of the growing church. The Jews, from the different synagogues out of Palestine, exasperated by the defection from their body of so eminent a person as Stephen, lost no opportunity of contending vehemently with him, and ultimately brought him before the Sanhedrim, to give an account of his belief and conduct. In answer, he commenced a fine oration, the object of which appears to have been to open, historically, the true design of the Jewish dispensation, and the consummation of that design in Christ. The object of this discourse has however been disputed; and it was, in fact, not fully developed by the speaker, as he was interrupted by the clamours of the mob, who 'were cut to the heart, and gnashed on him with their teeth.' He was however encouraged by a vision of 'heaven opened,' and of Christ glorified; on declaring which to the people, they rushed upon him, dragged him outside the city, and there stoned him to death, A.D. 33. With his last breath he invoked the pardon of God for his murderers. This was entirely an extrajudicial act, the effect of popular excitement; for the Sanhedrim did not convict him, and had indeed no power to inflict death.

STEPHEN I. was elected bishop of Rome after the death of Lucius, A.D. 253. He was applied to by the Christians of Gaul concerning some differences which they had with Martianus of Arles, who appears to have been unusually austere in matters of discipline. Next came the commotions among the Christians of Spain concerning the two bishops Basilides and Martialis, who were both deposed. Basilides went to Rome, and, it appears, prevailed upon Stephen to take his part; but the Spanish bishops applied to Cyprian of Carthage, who approved of the deposition of Basilides, and caused it to be confirmed by a council held in Africa. A controversy arose between Stephen and Cyprian concerning the baptism of heretics, but the authenticity of the letters of Cyprian and Firmilian concerning this dispute has been disputed by some church historians and critics. Stephen died A.D. 257, but the manner of his death is not clearly ascertained: the 'Acta S. Stephani' are not considered as genuine. Of Stephen's writings we have only fragments of epistles. (Dupin; Walch; Mosheim; Ceillier.)

STEPHEN II. was elected after Zacharias (A.D. 752), but died three days after his election, without being consecrated, for which reason he is generally omitted in the series of the popes.

STEPHEN III., a native of Rome, was elected the successor of Stephen II., and he is styled by many Stephen II. Astolphus, king of the Longobards, having shortly before driven the Byzantines out of Ravenna, and the Exarchate, and Pentapolis, marched towards Rome, in violation of the peace concluded between his predecessors and that see, and having advanced as far as Narni, sent messengers to the pope, requiring the inhabitants of Rome and its duchy to pay him a capitation tax, and acknowledge him for their liege lord, threatening to pillage Rome in case of refusal. Stephen, having applied in vain for assistance to the Eastern emperor Constantine Copronymus, who was at that time busy in breaking images and persecuting image worshippers, had recourse to Pepin, king of the Franks, whose accession to that throne in lieu of the deposed Childeric, the last nominal king of the Merovingian dynasty, had been countenanced and sanctioned by Zacharias, Stephen's predecessor. Pepin sent two legates, to endeavour to prevail upon Astolphus to desist from annoying the pope. Their remonstrations proving useless, pope Stephen determined to repair to France in company with Pepin's legates. Pepin received the pope with the greatest respect, and was crowned and anointed by him in the church of St. Denis, together with his two sons Charles and Carlomann. It was then agreed between Stephen and Pepin that Pepin should oblige Astolphus to evacuate not only the duchy of Rome, but also the Exarchate and Pentapolis, which he had taken from the Byzantines, and that those territories should be made over to St. Peter and the Roman see. Pepin, accompanied by Stephen, marched with an army into Italy, defeated Astolphus, besieged him in Pavia, and obliged him to promise to give up Ravenna with the Exarchate, which embraced the actual provinces called the Papal Legations, and the Pentapolis or present March of Ancona, including Urbino and Pesaro. Astolphus made the promise, and gave hostages to Pepin, who quickly returned to France (A.D. 754). In the following year however, Astolphus, having recruited his forces, marched straight to Rome, to which he laid siege, devastating the country around. Pope Stephen now wrote to Pepin in the most urgent manner, in the name of St. Peter: 'Petrus vocatus Apostolus à Jesu Christo Dei vivi filio: Viris excellentissimis Pipino, Carlo et Carolomanno tribus regibus,' &c., promising them and all the French people eternal life, if they would support the rights of St. Peter's see, but threatening them with eternal perdition if they neglected so to do. These remarkable letters of pope Stephen are in Baronius, Duchesne, and the Codex Carolinus. Pepin quickly repaired to Italy, again defeated Astolphus, who had been obliged to raise the siege of Rome in order to oppose him, and besieged him in Pavia. While Pepin was encamped before that city, an envoy appeared before him, sent by Constantine Copronymus, emperor of the East, who, after praising Pepin for having driven the Longobards out of the Exarchate, demanded its restitution to its former sovereign the emperor. Pepin replied that the Exarchate had belonged to the Longobards by right of conquest, and also by the will of the people, who had given themselves up to king Luitprand, in consequence of the persecution of the images ordered by the Greek emperors; and that now by the same right those provinces belonged to Pepin, who had taken them from the Longobards, and that he had thought it expedient to give them to the pope for the honour and advancement of the Catholic church, and to keep it free both from the heresies of the Greeks and from the ambition and rapacity of the Longobards. (Anastasius *in Vita Stephani III.*) Pepin, having dismissed the envoy with this answer, continued to press the siege of Pavia, and Astolphus was obliged to sue for peace. Pepin required him immediately to deliver to his commissioner Fulrad, abbot of St. Denis, the towns of the Exarchate and Pentapolis, and to cause them to be evacuated by the Longobards. This being done, Fulrad carried the keys of those towns to Rome, and deposited them on the sepulchre of the holy Apostle, together with the solemn deed of donation signed by Pepin, his two sons, and the principal barons and prelates of France. This act of donation is lost, but from some of the expressions, gathered from pope Stephen's letters, it appears that it was made to the blessed Peter, and the holy church of God, and 'to the Roman republic.' The city and duchy of Rome were therefore not included in the donation, as they had not been conquered either by the Longobards or by Pepin. The pope then entrusted the administration of the Exarchate to the archbishop of Ravenna. Some critics, especially French, and Sigonius himself, assume that Pepin gave to the pope only the 'utile dominium' of the Exarchate and Pentapolis, and retained for himself and his successors the 'jus imperii,' or sovereign rights.

Soon after this memorable transaction Astolphus died of an accident while hunting, and Desiderius, king of Tuscany,

was chosen by the Longobards for their king. Ratchis, brother of Astolphus who had formerly abdicated the crown and turned monk, left his convent and aspired again to the throne. Desiderius applied to pope Stephen, who ordered Ratchis to return to his convent. Ratchis obeyed, and Desiderius was acknowledged king. In the following year (April, 757) pope Stephen died, and was succeeded by Paul I. We have of pope Stephen's writings, besides his letters in the Codex Carolinus, his 'Responsa ad Gallos,' in Harduin's 'Concilia.'

STEPHEN IV., styled III. by some, a Sicilian by birth, was elected pope A.D. 768, more than a year after the death of Paul I., during which time one Constantine, a layman, and brother of Toto, duke of Nepi, intruded himself by force on the papal see, having obliged Gregory, bishop of Praeneste, to ordain and consecrate him. At last part of the Roman clergy, supported by the Longobard duke of Spoleto, who sent an armed force to Rome, overcame the faction of Constantine, who was deposed, deprived of his eyes, and shut up in a convent, and Stephen was elected. The new pope convoked a council in the Lateran, in which all the abettors of Constantine were degraded. Shortly after, new disturbances broke out in Rome, which induced Desiderius, king of the Longobards, to go thither with some troops. He had several interviews with pope Stephen in the Vatican Basilica outside of the walls, and assisted him in quelling the insurrection, the leaders of which had their eyes put out.

King Pepin being dead, the kingdom of the Franks was divided between his two sons, Charles and Carlomann. Bertha, Pepin's widow, having made a journey into Italy, saw king Desiderius, and arranged with him a matrimonial alliance between two of his daughters and her two sons. Pope Stephen, upon hearing this, wrote to the two kings of the Franks a very violent letter, which is contained in the Codex Carolinus, dissuading them from the proposed alliance, and asserting that it would be 'arrant folly to contaminate their noble legal race with the perfidious and infected race of the Longobards, who had brought leprosy into Italy, and who did not deserve to be reckoned among nations; that having promised to St. Peter to be friends of his friends, and enemies to his enemies, they ought to shun the alliance of the Longobards, who were enemies to Rome,' adding several scriptural passages which he made to bear upon the subject: he concluded by stating that he wrote this letter upon the sepulchre of the holy Apostle, and he threatened them with excommunication if they spurned his advice. The alliance however took place, at least in part; for Charles (afterwards Charlemagne) married Hermengarda, daughter of Desiderius, whom he repudiated a year after, to marry Hildegard, a German princess.

Sergius, archbishop of Ravenna, being dead, the archdeacon Leo was elected his successor; but Mauritius, duke of Rimini, went to Ravenna with an armed force, and violently placed in the archiepiscopal see the archivist Michael, a layman. Pope Stephen refused to consecrate Michael, who, after having stripped the church and treasury of many valuables, at last retired, and made room for Leo. It is said that king Desiderius favoured Michael. Pope Stephen, in the latter part of his pontificate, was at open variance with the king of the Longobards, who kept or recovered possession of Ferrara, Comacchio, and Faenza, which formed part of the long-disputed Exarchate. Pope Stephen died at the beginning of A. D. 772, and was succeeded by Adrian I.

STEPHEN V., a native of Rome, succeeded Leo III., A.D. 816. Shortly after his consecration he went to France to confer with the emperor Louis the Pious, whom he met at Orleans, and who received him with great honour. On his return to Rome, he died in the seventh month of his pontificate. He founded at Rome the monastery of Santa Prassede, which he gave to a congregation of Greek monks, who retained their own liturgy.

STEPHEN VI., a Roman, succeeded Adrian III. in the year 885. He found, on his accession, the Lateran palace stripped of its treasures and other valuables by the relatives and attendants of the late pope, according to the practice of those times. The public granaries were also empty, and the people of Rome were suffering from famine resulting from a bad harvest and from swarms of locusts which had desolated the country. Stephen ordered the fields to be sprinkled with holy water; but at the same time he promised a bounty in money for every measure of dead locusts which the peasants should bring him, and this had the effect of clearing the country of that scourge. He also sold his own property to relieve the poor. Pope Stephen had been consecrated by John, bishop of Pavia, who was one of the Imperial 'missi;' but the emperor Charles the Fat was angry because the new pope had not waited for his approbation, and he sent some of his officers to Rome to arrest him, but Stephen having forwarded the report of his election, made according to the canonical forms, and numerous attestations of both clergy and laity, the emperor was pacified. In the year 887 Charles the Fat was deposed, and his vast monarchy parcelled out. Berengarius, duke of Friuli, was elected by a part of the Italian barons king of Italy; but he found a rival in Guy, duke of Spoleto, who overthrew Berengarius in battle, and was crowned at Rome by the pope, in February, 891, with the title of emperor, 'Wido Imperator Augustus.' Soon after this solemnity pope Stephen died, and was succeeded by Formosus. Pope Stephen is said by Gulielmus Bibliothecarius to have been a man of learning: he collected manuscripts, which he gave to the Basilica of St. Paul.

STEPHEN VII., bishop of Anagni, and a native of Rome, succeeded (A.D. 896) Benedict VI., who had not lived a month after his election, which took place on the death of Formosus. Stephen, from what motive is not clearly ascertained, persecuted with the greatest bitterness the memory of pope Formosus, caused his body to be disinterred and stripped of its pontifical garments, and thrown into a common grave among laymen. He justified himself by the fact that Formosus, before his elevation to the papacy, had been excommunicated by pope John VIII., in consequence of the frequent factious strifes which often broke out at Rome. Stephen also annulled all the acts and decrees of Formosus. This affair of Formosus gave rise to much controversy, which lasted during several successive pontificates; and a contemporary writer called Auxilius wrote in defence of the memory of Formosus, 'De Ordinatione Formosi Libri Duo.' In the year 897 an insurrection of the friends of Formosus broke out at Rome, and pope Stephen was seized, cast into prison, and strangled. He was succeeded by Romanus, who annulled all Stephen's acts as to Formosus.

STEPHEN VIII. succeeded Leo VI., A.D. 928. This was the period when Marozia, and her husband Guido, duke of Tuscany, ruled in Rome. They had put to death pope John X., and are said to have done the same to his successor Leo VI., whose pontificate lasted only seven months. The election of Stephen is supposed therefore to have been effected with their approbation; but we have no historical record concerning the particulars of his pontificate. The tenth century is the truly dark age of Italian history. Stephen VIII., styled by some VII., died in December, 930, and was succeeded by John XI., son of Marozia.

STEPHEN IX. succeeded Leo VII., A.D. 939. Rome was then governed by Alberic, son of Marozia, who assumed the title of 'prince and senator of all the Romans.' Little or nothing is known of Stephen IX.'s pontificate. Martinus Polonus alone, a chronicler of dubious authority, says he was roughly handled by the Romans in a popular tumult, and was crippled for the rest of his life. He died A.D. 942, and was succeeded by Martinus III.

STEPHEN X., styled IX. by some, Cardinal Frederic, abbot of Monte Casino, and brother of Godfrey, duke of Tuscany, succeeded Victor II., A.D. 1057. He had been legate of Leo. IX. to the court of Constantinople, and was learned in controversial divinity. His election is said to have been unanimous. By the advice of the monk Hildebrand (afterwards Gregory VII.), he sent two legates to Milan to enforce the decrees concerning the celibacy of the clergy, which the church of Milan had not yet adopted. This dispute had begun in 1021, at the council of Pavia, and it lasted for nearly half a century. Stephen issued also several bulls against simony, which was prevalent in his time. He sent for the learned Petrus Damianus, who had retired to a secluded cloister, and obliged him to come to Rome under pain of excommunication, and made him cardinal and bishop of Ostia. The pope also visited his former monastery of Monte Casino, in which he enforced a strict discipline. He also issued a bull exempting the clergy from the jurisdiction of the lay courts, and from paying tribute to laymen. From some passages of Leo Ostiensis and other chroniclers it has been surmised that he intended to make his brother Godfrey king of Italy. But the pope fell ill,

and died at the beginning of 1058. On his deathbed he recommended the clergy and people to wait for the return of Hildebrand from Germany before they elected his successor, but the advice was not followed, and a schism ensued. [BENEDICT X.; NICHOLAS II.]

STEPHEN, ST., first king of Hungary, son of the Magyar chief Geysa, and Sarolta, the daughter of Gyula, a Hungarian nobleman who had been baptized in Greece, was born about 979, at Gran (*Estragan*, the antient Strigonium).

His father Geysa (Gyözö, *i.e.* Victor), whose fierce and indomitable character the Christian Sarolta had succeeded in softening, allowed Piligrin, bishop of Lorch, to preach the gospel to the Magyars; but these first attempts proved unsuccessful, and it was only at a subsequent period, when Geysa himself was converted, that a few of his countrymen followed his example. The number was however greatly increased upon the arrival in Hungary of St. Adalbert, who advised Geysa to allow Christians to settle there; and in consequence of this permission being granted, a number of Germans and Italians established themselves in the neighbourhood of the capital, Gran. The majority of the Hungarians being however still attached to their gods, persecution as well as other means of conversion were used against them. In the midst of preparations for a powerful attack against his heathen countrymen Geysa died, and Stephen succeeded him in 997.

The legend says that an angel had announced to Geysa the birth of a son, and that St. Stephen, the protomartyr, appeared to Sarolta, and bade her call her offspring after him. The name which he bore before his baptism was Vâik, according to Mailath. Great care was taken by his mother that he should receive a good education; Count Deodatus à San Severino, in Apulia, was appointed his instructor, and St. Adalbert, of Prague, baptized him in 995. Shortly after this he married Gisela, the sister of the emperor Otho III.

The dissatisfied Magyars, though they had hitherto refrained from any acts of violence against the Christians, who enjoyed the powerful protection of Geysa, now began to make open resistance. The youthful inexperience of Stephen, who had scarcely assumed the reins of government, seemed to give them hopes of succeeding in their attempts to check the progress of Christianity and restore their antient religion. Indeed it appears that when Kupan, the count of Simegh, had consented to lead the heathen Magyars, a number of those who had received Christian baptism joined his standard. In addition to this, so wavering was the faith of those who remained with Stephen, that the youthful chief could only rely upon the support of the foreigners. Kupan had assembled all his forces, and marched towards Weszprim, in the neighbourhood of which town Stephen met him. After a desperate battle, in which Kupan lost his life, the victory so decidedly leaned towards the side of the Christians, that the few remaining adherents of the party of Kupan quitted it. For the purpose of securing the possession of his throne, Stephen sent an embassy to Pope Sylvester II., at the head of which was Astricus or Anasbasius, bishop of the newly erected see of Kolotz, who was instructed to obtain the title of king for Stephen. Astricus soon returned with a crown and a deed of the pope, which gave Stephen unlimited power in the ecclesiastical affairs of his country. The coronation took place on the 15th of August, 1000. From the time of his assuming the title of king, the peaceful occupations of Stephen were only interrupted by a few warlike incursions, all of which he successfully repelled.

In 1002 Gyula, his cousin, rebelled against him, and publicly abjured Christianity. After a short campaign he was taken prisoner with his two sons, and Zóltan was appointed governor of Transylvania in his stead. The Bulgarians having assisted Gyula in his rebellion, and threatening to make an incursion into the kingdom, Stephen led an expedition against their chief Kean, and gained a decisive victory over him. The third invasion against Stephen was one conducted by Henry, the son of the emperor Conrad, who had already advanced as far as the Raab with a powerful army. The occasion of this seems to have been a misunderstanding; for after some negociations the army returned without having fought a single battle. These were the only instances in Stephen's long reign which obliged him to have recourse to arms. Indeed his court was so well known for the security which it afforded, that the two English princes Edwin and Edward, who had been exiled by Canute, came over to Hungary and lived under king Stephen's protection. The whole of his attention was given to the firm establishment of Christianity, and no means were neglected by him which could induce the few who still persevered in heathenish practices to adopt it.

He divided Hungary into ten bishoprics, which were plentifully supplied with monasteries built by Greek architects. Schools were also established, the first and best of which was that of St. Gerard, who had been tutor to prince Emeric, the king's son. It was afterwards entrusted to the direction of Walter, a monk of Bákony Bél, the fifth monastery founded by Stephen. The country itself being now provided with ecclesiastical and school establishments, a monastery was built at Ravenna for the use of Magyar pilgrims on their way to Rome, where the munificent king had erected a college with a foundation for ten canons, and an inn for his subjects whom the desire of learning might lead to Rome. A large convent in the neighbourhood of Constantinople was the resting-place for Hungarian monks who wished to join their brethren at Jerusalem, and who were entirely supported by the king.

These and many other pious and charitable institutions of St. Stephen, joined to his own exemplary life and precepts, soon rooted out the last remnants of paganism. His constitution, which is undoubtedly the foundation of the present Hungarian government, but of which we have no well authenticated remains, finished the work of civilization which he had begun thirty years before.

At this period of his life, being fifty-one years of age, he lost his son Emeric, who, under the able tuition of Gerard, had all the accomplishments of his time, and was in every respect worthy of his father. Emeric was married to the daughter of Kresimir, king of Croatia, but he died without issue.

Stephen's grief for the loss of his son was increased by the treachery Gisela, who put out the eyes of Vazul, whom Stephen had designed for his successor, in order that her own son Peter might succeed to the throne. These causes of sorrow so affected Stephen's health that they brought on an illness which afflicted him till his death. About this time an attempt was made against his life by a murderer, who was incited by four of the principal men of the court. On the failure of his attempt, the miscreant fell upon his knees and confessed all. Stephen gave a general pardon to all who were concerned in the crime. He died on the 15th of August, 1038 (the day of his coronation), forty-one years after the death of his father. In 1083 his relics were enshrined by St. Ladislaus, in a rich chapel which bears his name, in the church of our Lady of Buda. The 20th of August, the day of the translation of his relics, is kept in Hungary as a festival.

St. Stephen was canonized by Benedict IX.; and pope Innocent XI., in 1686, appointed his festival to be kept on the 2nd of September, the emperor Leopold having on that day recovered Buda from the Turks. (Chartuitius, *Vita S. Stephani.*)

STEPHEN II., king of Hungary, son of Koloman, whom he succeeded in 1114, at the age of fourteen. He was of a weak intellect, and unwilling to submit to the judgment of his advisers, but was accustomed to act from the impulse of the moment. This quality gave him the name of 'the Lightning, or 'the Thunderer,' and rendered him odious to his subjects. Soon after his accession to the throne he made war on the Venetians, who could not be reconciled to the loss of Dalmatia, which had been taken from them during the reign of Stephen's father. They sent a fleet, with a considerable army, under the Doge Ordelaf Faledro, who however did not recover this province, the possession of which was of the greatest importance to the republic. The hostilities, which lasted two years, ended with a treaty which secured the mainland of Dalmatia to Stephen, whilst Venice obtained the adjoining islands. This transaction was scarcely concluded, when Stephen went (1116) to meet Wladislaw, the chief of the Bohemians, for the purpose of renewing the treaties of friendship which had long existed between the two countries. Unfortunately, through the treachery of an individual whose name was Solth, the meeting terminated in a quarrel attended with bloodshed; but after a few months the traitor was executed, and the old treaty renewed. The taste for war which Stephen showed throughout his reign, and the eagerness with which he sought every opportunity of satisfying his warlike disposition, countenance the assertions of some writers, that he himself

was a participator in this dishonourable transaction. In the two following years Stephen invaded Poland and Austria, from which expeditions he derived no material benefit. In 1119 he resolved upon an incursion into Austria, thinking that the great forces which he had assembled, and the apparent carelessness of the empire, would secure his success. But the emperor Leopold, after a decisive battle, in which the Hungarian army was completely beaten and obliged to retreat, pursued them as far as Eisenberg, and compelled Stephen to desist from his incursions.

The bad feeling which such acts had produced in the people was only checked by the great respect for kingly authority; but Stephen at last excited general indignation by filling the country with foreigners, to whom he showed a decided preference. This foolish policy was followed, in 1127, by a war with the grand-duke of Muscovy, Wladimir Monomakh. Yaroslaw, the exiled prince of Wladimir, applied to Stephen for aid. The Hungarian army marched into Russia, and advanced without opposition as far as Wladimir. At this crisis Yaroslaw died, and with his death the cause of the war ceased. But instead of returning, Stephen insisted upon storming the town; and in consequence of his obstinacy, the chief nobles of his army, with Kozma Peznan at their head, declared that if he would not immediately follow them into their own country, they would elect another king, and leave him to the mercy of the Russians. Intimidated by these threats, Stephen returned to Hungary; but his conduct compelled many of those who were concerned in the revolt to fly to Constantinople. Here they were well received by the emperor John II., who, upon Stephen's threatening to invade the empire, sent a powerful army against him, which completely defeated the Hungarians at Uj Palanka. When peace was restored, Stephen adopted Bela, the son of his relative Amos, who had been obliged to seek protection at the court of Constantinople, and resigned in his favour in 1131. He then entered a monastery, and died at Waradin, in the thirty-first year of his age.

STEPHEN III. was crowned king of Hungary in 1161, under unfavourable circumstances, arising from the influence which the emperor of Constantinople had exercised over Hungary during the reign of his father. Although Stephen had legitimate claims to the throne, and was generally beloved by the Hungarian nobles, the emperor Manuel did not approve of his spirit of independence, and signified to the Hungarians that unless they elected Ladislaus, the brother of the late king, he would invade the country. Ladislaus had been brought up at the Byzantine court, and had the Greek interest much more at heart than the Hungarian. Terrified by the approach of a formidable army, the Hungarian nobles elected Ladislas, who however died in 1161.

STEPHEN IV. On the death of Ladislaus, Stephen IV. was forced upon the Hungarians by the emperor Manuel; but no man could be less acceptable to the Hungarians than the debauched uncle of the unfortunate Stephen III. A revolt soon compelled him to seek refuge at the court of his patron, and the lawful king, Stephen III., was unanimously re-elected. During the usurpation of his uncle, Stephen lived under the protection of the archbishop of Gran, Luke Banfi. Manuel seemed to approve of the newly elected king, and gave his daughter in marriage to Bela, the brother of Stephen, on condition that the prince should live at Constantinople. Stephen agreed to this; but upon the arrival of Bela at Constantinople, the emperor claimed his heritage, which consisted of Dalmatia. Stephen refused to admit his claim; whereupon his uncle, Stephen IV., re-appeared at the instigation of Manuel, and commenced hostilities. He was however defeated in a battle by his nephew, and obliged to fly to Semlin, where he died in 1163. Soon after his death Semlin was taken, the kingdom cleared of the partisans of the Greek cause, and in an expedition into Dalmatia, which was conducted by Stephen himself, in 1165, this province was recovered from the hands of Manuel. But whilst engaged in the western parts of his kingdom, a Greek army appeared in Hungary. Stephen went to meet it; and a decisive battle, in which the Hungarians were defeated, secured the influence of Greece in Hungary. Stephen died in 1173, and was succeeded by his brother Bela III.

STEPHEN V., king of Hungary, succeeded his father Bela in 1270, and began his reign by a war against Ottocar, king of the Bohemians, whom he defeated. A subsequent campaign against the Bulgarians was crowned with success; but the course of his victories was interrupted by his death, which occurred in 1272.

This king is sometimes called Stephen IV. by those who do not recognise the usurper of that name.

(Thwrocz, *Chronica Hungarorum*; Ranzanus, *Epitome rerum Hungaricarum*; Bonfinius, *Rerum Hungaricarum Decades Quatuor*; Mailáth, *Geschichte der Magyaren*.)

STEPHEN, king of England, born A.D. 1105, was the third of the four sons of Stephen, earl of Blois, by Adela, daughter of William the Conqueror; and was consequently nephew of Henry I., cousin to that king's daughter the empress Matilda, and second cousin to Matilda's son, who became king of England as Henry II. Having been early brought over to England by his uncle Henry I., that king, with whom he became a great favourite, besides bestowing upon him several valuable estates here, made him earl of Mortagne in Normandy. Dr. Lingard says that Stephen 'had earned by his valour in the field of Tenchebrai the Norman earldom of Mortoil' (*Hist. of Eng.*, i. 158). But when the battle of Tenchebrai was fought, in 1106 [HENRY I.], Stephen was only about a twelvemonth old. Henry also procured for him a marriage with Matilda, the daughter and heiress of Eustace, earl of Boulogne (younger brother of the famous Godfrey and Baldwin, kings of Jerusalem), by which he acquired that earldom, and also a new alliance with the royal families both of England and Scotland, for the mother of Matilda of Boulogne was Maria, daughter of Malcolm Canmore, and a younger sister of Henry's queen Matilda (the good queen Maud). As Stephen therefore was the nephew of Henry I., so his wife was the niece of Henry's queen; and by this match the issue of Stephen, as well as the issue of Henry, might boast of inheriting the blood of the old Saxon royal family, as being equally sprung from Malcolm's queen Margaret, the sister of Edgar Atheling, a circumstance by no means without its influence in the contentions of the two lines.

When Henry, after the loss of his son and the failure of issue by his second wife, determined upon securing the succession to the crown for his daughter the empress Matilda, the two individuals upon whom he appears to have principally relied for the support of that arrangement were his natural son Robert, earl of Gloucester, and his nephew Stephen. It is not improbable that both may have meditated the attempt which Stephen actually made, and that, if the crown upon Henry's death had not been seized by him, it might have been clutched at by Gloucester. The notions of that age were by no means so settled in favour of legitimate birth as to have prevented the son of the late king, although illegitimate, from having a fair chance in such a competition against his nephew.

Perhaps Henry himself was not without his fears of one or both. He must have felt at least that the existence of two males so nearly connected with the royal house, and distinguished both for military talent and popular manners, tended to make still more precarious the success of his novel project of a woman-king, a thing opposed to all the notions and habits of the Gothic nations, and (if we except the single instance of a wife of one of the kings of the West Saxons, who is said to have retained the government in her hands for a year after the death of her husband, and then to have been expelled with disdain by the nobles, who would not fight under a woman) unexampled either in England, or in France, or in Normandy, or in the kingdoms of Denmark and Norway, whence the Normans came. At the same time, it was obviously much better for Matilda that she should have two such near male relations than if she had had only one; seeing that, if she had to fear a rival in one of them, she might count with equal certainty upon having a defender in the other. But that which after all gave her her best chance was the circumstance of her having had the good fortune to give birth to a son a few years before her father's death. Indeed she had borne two sons to her second husband before her father died. Had it not been for these lucky accidents, it may be doubted if all her father's provident arrangements would have secured the recognition of Matilda's pretensions for a moment after the throne became vacant. But for the existence of the infant Henry of Anjou, or of his younger brother, at the time of his grandfather's death, the crown might probably have been Stephen's without striking a blow—unless there had ensued a fight for it between him and his cousin Gloucester.

In 1125, immediately after the death of her first husband the emperor Henry V. (whom she was suspected of having made away with), Henry had sent for his daughter to Nor-

mandy; and, having the next year brought her over to England, he collected all the chief persons of the realm about him at Windsor while he kept his Christmas, and, having there by presents and promises engaged those among them of greatest influence to support his views, he came to London, and, having proposed the matter in a council consisting of the archbishops, bishops, abbots, earls, and all the thanes, obtained, in the beginning of January, 1127, though not, says Malmesbury, without great and long deliberation, the unanimous promise of the assembly, that, if he should die without male issue, they would receive Matilda as his successor. Every individual present who seemed to be of any note—quicunque in eodem concilio alicujus videbatur esse momenti (to adhere to Malmesbury's remarkable expression)—took a solemn oath to that effect; first the archbishop of Canterbury and the other bishops and abbots, then the king of Scotland on account of the fiefs he held of the English crown, then Stephen, earl of Boulogne and Mortagne, then the earl of Gloucester, then the other barons. 'But betwixt the earl of Boulogne and the earl of Gloucester,' says Lord Lyttelton, 'there was a dispute about precedence; not (as I apprehend) which should be foremost to show his zeal for Matilda's succession (though that might be the pretence for it), but to determine a question of the greatest consequence if she should die before the king, namely, which of the two was nearest to the throne. And its being now decided in favour of Stephen, on account of the illegitimacy of his competitor, was of no little service to him afterwards, even against Matilda herself, as he was thereby acknowledged first prince of the blood. It also removed out of the way of Stephen a very considerable obstacle to his ambition, by the discouragement it gave in the eye of the public to the earl of Gloucester's pretensions, who wanted not precedents, either in England or Normandy, to authorise his aspiring to the throne of his father in default of lawful issue male. But a solemn determination, which assigned the precedence to the nephew of the king above his natural son, was a prejudication of the right of succession in favour of the former.' A few months after this Matilda was married to Geoffrey Plantagenet, the son of the earl of Anjou; and in the year 1131, when she was in England, having already quarrelled with her husband, the oath of fealty to her was again taken by the bishops and nobility at a grand council held at Northampton. And two years after, on the birth of Matilda's first son Henry, it was once more renewed, in a council held at Oxford, both to her and to her son.

Nevertheless, as soon as Henry had expired in Normandy, 2nd December, 1135 Stephen, who, as well as Gloucester, had been for some time in attendance on the dying king, instantly set out for England, and taking ship at Whitsand, near Calais, the usual port of embarkation, landed on the coast of Kent. It appears that, foreseeing his uncle's decease, he had already secured the support of a powerful faction of the clergy and nobility, by means of his younger brother Henry, who, having also stood high in the favour of the late king, had been placed by him in the bishopric of Winchester, and had succeeded in winning over to his brother's interest the most influential subject in the kingdom, Roger, bishop of Salisbury, who, as grand justiciary, was the supreme governor of the realm during the vacancy of the throne. Of Stephen's two eldest brothers, it may be here mentioned that William, the eldest, was almost an idiot, and that the other, Theobald, had succeeded to his father's earldom of Blois; so that Stephen, in aspiring to the English crown, did not find either of them in his way. The politic and zealous management of his brother Henry had also gained for him the support of William de Pont de l'Arche, who held the castle of Winchester and the key of the royal treasures deposited there. The consequence was, that although Stephen was refused admission by the inhabitants both at Dover and at Canterbury, he was received with warm welcome by those of London and Winchester; and after Hugh Bigot, earl of Norfolk, the steward of the royal household, had, to remove the scruples, real or affected, of some of his adherents, boldly sworn that Henry on his deathbed had disinherited his daughter and her issue, and left the crown to his nephew, it was resolved by the clergy and nobility who had gathered about him that he should be crowned forthwith, and the ceremony was accordingly performed at Westminster on the 26th of December, St. Stephen's-day, by the archbishop of Canterbury, assisted by the bishops of Salisbury and Winchester. The commencement of the reign of Stephen is reckoned from that day.

At his coronation Stephen swore, 1, That on all occasions of episcopal vacancies he would appoint a new prelate within a certain time, and meanwhile would leave the temporalities of the see in the charge of some ecclesiastic; 2, That he would make no addition to the royal forests, but would, on the contrary, restore to their owners such lands as had been made forest by his predecessor; 3, That he would abolish the tax called Danegelt, which, after having been given up by the Confessor, had been restored by the Norman kings. On the other hand, the bishops tendered their allegiance only for so long as the king should maintain the privileges of the church; and the lay barons appear to have also qualified their oath by a similar condition as to his preservation of their estates and honours. Nothing like this had taken place at the commencement of any previous reign since the Conquest.

In January of the following year, 1136, after seeing the body of the late king interred at Reading, Stephen convened a great council of the bishops and the nobility at Oxford, and there signed a charter of the liberties of the church and state, in which he styled himself 'Stephen, by the grace of God, elected king of the English by assent of the clergy and the people, consecrated by William, archbishop of Canterbury and legate of the holy Roman church, and confirmed by Innocent the Pontifex of the holy Roman see.' He had shortly before this obtained a bull from pope Innocent, confirming his election. In this charter he repeated more distinctly the engagements under which he had come at his coronation, declaring besides that he would cause to be observed all the antient and just laws of the kingdom. There is also a shorter charter of Stephen's, dated at London, which seems to have preceded this, and which was probably granted at or immediately after his coronation. In that he expressly grants to his French and English subjects all the good laws and good customs which they had in the time of the Confessor, a clause which is not found in the larger charter. The confirming clause of the latter also has the qualification, '*salva regia et justa dignitate mea*'—saving *my royal* and just dignity,—which the other is without.

Meanwhile a feeble attempt had been made by Matilda and her husband to take possession of Normandy; but the Normans themselves, without any assistance from Stephen, soon drove out the army of Angevins which had entered their country. In England at this moment not a hand or voice was lifted up for the daughter of the late king. Even the earl of Gloucester came forward with the other barons, and did homage, and took the oath of fealty, to Stephen.

After a short while, however, opposition arose in various quarters. In the spring of the year 1136, king David of Scotland, Matilda's uncle, advancing at the head of an army, overran the northern counties, and compelled the barons of those parts to swear fealty to Matilda, and to give hostages for the performance of their oath; and although he agreed to a peace when Stephen marched against him, and restored the lands and castles he had taken, he refused to do homage to the king of England for his possessions in that country. He suffered his eldest son Prince Henry however to do homage for the honour of Huntingdon, which, with the towns of Carlisle and Doncaster, was conferred upon him by Stephen. Meanwhile, during Stephen's detention on the northern borders, an insurrection in favour of Matilda broke out in Wales, which he never could effectually suppress, but was obliged to satisfy himself with merely endeavouring to prevent from extending itself beyond that quarter of the kingdom. Then, although he had obtained the investiture of the duchy of Normandy from the French king Louis, it soon appeared that his possession of the country was only to be retained by force of arms, and that while he had to keep back with the one hand the persevering attacks of the Angevins, he had an almost equally troublesome enemy to keep down with the other in the native chiefs, a large proportion of whom, sometimes arraying themselves on his side, sometimes on that of Matilda, evidently aimed at taking advantage of the contest between the two rivals, to throw off the yoke of the one as well as of the other, and to secure, if not the national independence, at least their individual emancipation from all superiority. And the same spirit quickly began to show and spread itself in England. In some districts the standard of Matilda was raised by the earl of Gloucester, and

various places of strength were seized upon and garrisoned in her name; elsewhere the barons fortified their castles on their own account, and set up each as an independent chieftain. Stephen had his hands full of work with all this disorder and rebellion in the south, when the king of Scotland again appeared on the northern borders. After having ravaged Northumberland with unusual ferocity in the winter of 1137, David and his half-barbarian host retired to Roxburgh, on the approach of the English king in the beginning of the following year; but as soon as Stephen was recalled to the south, the Scots again crossed the border in the end of March, 1138. They had taken the castle of Norham, and laid siege to other fortresses, when they were met by Thurstin, archbishop of York, at the head of an army composed of the retainers of the northern English barons, and defeated by him in the famous battle of the Standard, fought on the 22nd of August, 1138, on Cutton Moor, in the neighbourhood of Northallerton. Peace however was not concluded with the Scots till the 9th of April in the following year, when Stephen found himself under the necessity of yielding up to Prince Henry the earldom of Northumberland, with the exception of the forts of Newcastle and Bamborough, for which he engaged to make over to him estates of equivalent value in the south of England.

But by this time the unfortunate English king had found another, and, as it turned out, by far his most formidable enemy. He had quarrelled with the church. Resolved to reduce the inordinate power of Roger, bishop of Salisbury, and his two nephews, Alexander and Nigel, bishops of Lincoln and Ely, he had at a council held at Oxford, in June, 1138, arrested Roger and Alexander; and although Nigel made his escape, he was eventually compelled to surrender his castle of Devizes, as his brother and his uncle had been to give up theirs of Newark, Salisbury, Sherburn, and Malmesbury. The inflammation excited in the whole ecclesiastical body by this attack was terrific. Even the king's brother, the bishop of Winchester, who had been lately made papal legate, was either carried away by the general feeling of his order, or, if he did not share in that feeling, found it would be in vain for him to resist it. He summoned his brother to answer for what he had done before a synod of bishops, which met at Winchester. Stephen complied so far as to send one of his ministers to plead for him, who, when the decision upon a preliminary question had been given against the king, appealed to Rome; on which the legate dissolved the synod, on the 1st of September, 1139. On the last day of the same month Matilda landed on the coast of Suffolk, and immediately after the earl of Gloucester unfurled his standard in the west. The war spread rapidly over the whole kingdom. At length, on the 23rd of February, 1141, Stephen, while besieging the castle of Lincoln, which was held by Ranulph, earl of Chester, was attacked by the earl of Gloucester, and being taken prisoner, was immediately, by Matilda's order, consigned in chains to the castle of Bristol.

On that day month Matilda and her brother, attended by a numerous body of barons of their party, met the legate on the open downs in the neighbourhood of Winchester, when it was solemnly agreed that Henry and the church should acknowledge her as their sovereign, on condition that he should be made her first minister, and especially that all vacant bishoprics and abbacies should be filled up on his nomination. Soon after this the archbishop of Canterbury and all the other bishops gave in their adherence. In the beginning of April the heads of the church met on the summons of the legate at his episcopal city of Winchester; and there he addressed them in a long speech, which Malmesbury, who heard it, has preserved; and in the end the meeting unanimously agreed to confirm his treaty with Matilda. A remarkable circumstance mentioned in the account of this meeting is the appearance of certain deputies from the citizens of London, who, it is stated, on account of the greatness of their city were considered as nobles in England, and who had been summoned to give their attendance by the legate, although the assembly was otherwise composed only of ecclesiastics. They at first stood up for Stephen, but were ultimately persuaded to concur with the rest of the meeting.

But the folly, rapacity, and insolence which Matilda now displayed in her triumph, were soon found to be insupportable by all parties. Taking advantage of the strong popular feeling of disgust, Stephen's queen Matilda, who had remained in arms for her husband in the county of Kent, made her appearance before London while the empress lay there awaiting her coronation; and she barely contrived, by springing from table and mounting her horse, to effect her escape to Oxford. The legate now joined his sister-in-law and the Londoners; the empress, with the king of Scots, the earl of Gloucester, and others of her principal adherents, besieged in the castle of Winchester, fled from that stronghold on the morning of Sunday, the 14th of September, when, being immediately pursued, many of the party were killed; most of the rest, including the earl of Gloucester, were taken prisoners, and Matilda herself with difficulty escaped to the castle of Devizes. Negociations were now opened, the result of which was that in the beginning of November Gloucester was exchanged for Stephen. When his brother was thus again at liberty, the legate once more summoned a clerical synod at Westminster, on the 7th of December, at which he defended his abandonment of the cause of Matilda, and as usual carried his brethren along with him in his new course of politics. Stephen himself, having appeared among them, addressed them with pathetic eloquence on the wrongs and indignities he had sustained; and they ended by resolving unanimously to excommunicate all who should adhere to 'the countess of Anjou.'

The war now recommenced after Stephen had recovered from an illness which confined him for some months, and Gloucester had returned from the Continent, whither he had gone to endeavour to persuade Matilda's husband to come over to her assistance, an attempt in which he met with no success, although Geoffrey consented to entrust his eldest son Henry to the earl's care. In the end of September, 1142, Stephen laid siege to the castle of Oxford, in which Matilda resided; but when the garrison, from want of provisions, could hold out no longer, the empress, on the 20th of December, in a severe frost, and while the ground was covered with snow, slipped out at an early hour in the morning attended by three knights, made her way through the posts, crossed the Thames on the ice, walked to Abingdon, and thence rode to Wallingford. Other sieges, battles, and skirmishes followed, and the kingdom remained subject generally in the eastern counties to Stephen, in the western to Matilda, till the death of the earl of Gloucester, the main support of the latter, in 1146, upon which she retired to Normandy. But her absence brought little more quiet to Stephen. The next two or three years of his reign were disturbed by a formidable rebellion of a confederacy of the barons headed by Ranulf, earl of Chester, and also by another quarrel with the clergy, whose hostility Stephen brought upon himself this time by his support of their old leader his brother Henry, when that intriguing and ambitious prelate, whom the pope, at the instigation of Theobald, archbishop of Canterbury, had deprived of his office of legate, sought to avenge himself on the primate by the aid of the royal authority. Matters proceeded so far that Theobald at last published a sentence of interdict, the first of which this country had ever been the object, against all the dominions of the English king; and Stephen, assailed by the cries of the alarmed people, found himself forced to yield. But his last and worst antagonist now appeared in the person of Matilda's son Henry, who, having by the death of his father, in September, 1151, become earl of Anjou, and having soon after added to his paternal dominions the territories of Poitou and Aquitaine by his marriage with Eleanor, the divorced wife of Louis VII. of France, landed at Wareham, on the 6th of January, 1153, at the head of a force of only 3000 foot and 140 knights, which however was soon augmented by the junction of considerable numbers of his mother's friends. Yet no swords were crossed by these rival claimants of the same crown. Henry having forced his way into the town of Malmesbury, lay there, while the Avon, rendered impassable by the rains, prevented Stephen from attacking him. Stephen then retired to London, on which Henry advanced to Wallingford; but when Stephen had also marched to this point, and both parties were preparing for battle, the principal persons in the two armies, at the suggestion of the earl of Arundel, interfered, and an agreement was made, by which the effusion of blood was prevented, and which was confirmed in a great council held at Winchester in November following. By this compact, Stephen, whose eldest son Eustace, fortunately for the peace of his country, died suddenly at Canterbury during the negociation, having been seized, it is said, with fever and

phrenzy, while he sat at table, constituted Henry, whom he styled duke of Normandy, 'his successor in the kingdom of England, and his heir by hereditary right.' Henry in the meantime did homage and swore fealty to Stephen; Stephen's surviving son William did homage to Henry, and received from him a grant of all the lands and honours held by his father before his accession to the throne; and, lastly, the bishops and abbots, the earls and barons, and the inhabitants of all the boroughs in the kingdom, swore fealty to both the king and the duke. One of the most strenuous supporters of this arrangement was the bishop of Winchester. Stephen survived its ratification not quite a year; he died suddenly in a convent at Dover, on the 25th of October, 1154, being in the 50th year of his age, and having reigned nineteen years all but two months. [HENRY II.]

England during the whole reign of Stephen was probably in a state of greater anarchy and misery than it had ever known since the first settlement of the Saxons, or has ever experienced in the worst of the intestine wars and confusions of which it has since been the theatre. Indeed the country appears to have got far back towards barbarism. 'In this king's time,' says the Saxon Chronicle, 'all was dissension, and evil, and rapine. . . . Thou mightest go a whole day's journey, and not find a man sitting in a town, nor an acre of land tilled. The poor died of hunger; and those who had been men well to do begged for bread. Never was more mischief done by heathen invaders. . . . To till the ground was to plough the sands of the sea. This lasted the nineteen years that Stephen was king, and it grew continually worse and worse.'

Yet Stephen personally appears to have had many qualities which would have adorned a throne more fortunately circumstanced. The party zeal of the old historians has given very opposite representations of his character; but his general conduct, and the best or most impartial authorities, bear out what has been said of him by Stow:—'This was a noble man and hardy, of passing comely favour and personage: he excelled in martial policy, gentleness, and liberality towards all men, especially in the beginning; and, although he had continual war, yet did he never burthen his commons with exactions.' His valour and clemency indeed, as well as the beauty of his person, are admitted on all hands, and are attested by the whole of his career, and by many remarkable incidents. He is especially spoken of in terms of the warmest eulogy by one contemporary writer, the author of the Life of St. Cuthbert, lately printed by the Surtees Society, 'Reginaldi Monachi Dunelmensis Libellus de Admirandis Beati Cuthberti Virtutibus,' 8vo., Lon., 1835. See his 64th chapter.

By his queen Matilda, who died 3rd May, 1151, Stephen had the following sons and daughters:—1, Baldwin, who died in infancy; 2, Eustace, after his father's acquisition of the crown styled earl of Boulogne, who was born in 1135, married, in 1138, Constance, daughter of Louis VI. and sister of Louis VII. of France (afterwards the wife of Raymond III., earl of Toulouse), and, as already mentioned, died 10th of August, 1153, without issue; 3, William, who married Isabel, daughter and heiress of William, earl of Warren and Surrey (afterwards the wife of Hamlyn Plantagenet, natural son of Geoffrey, earl of Anjou), became earl of Mortagne and Boulogne after the death of his elder brother, and died without issue in October, 1160; 4, Maud, who died in childhood; 5, Mary, who, after becoming a nun, and abbess of the nunnery of Ramsey in Hampshire, succeeded, on the death of her brother William, to his honours of Boulogne and Mortagne, and some years afterwards married Matthew, son of Theodoric of Alsace, earl of Flanders, with whom she lived ten years, and was then, in 1189, divorced by the pope and sent back to her convent, after having borne Theodoric two daughters, the youngest of whom, Maud, through her granddaughter Elizabeth, the wife of Albert I., duke of Brunswick, is among the ancestors of the present English royal family. Two natural sons are also attributed to Stephen: William, of whom nothing is known except the name; and Gervais, by a lady named Danota, made by his father abbot of Westminster, which dignity he held till his death, 26th August, 1160. Stephen's younger brother Henry, the bishop of Winchester, who figures so conspicuously throughout the reign, died 6th August, 1171.

The chief contemporary chroniclers of the time of Stephen are, the writers of the 'Saxon Chronicle,' the anonymous author of the 'Gesta Stephani' (published in Duchesne), Richard, prior of Hexham (Hagulstadensis), Serlo, and Ailred, abbot of Rivault (all in Twysden's 'Decem Scriptores'), William of Malmesbury, and Henry of Huntingdon. Many additional facts are also mentioned by Ralph de Diceto, Brompton, Gervas of Canterbury, and other later writers.

STEPHEN, BATHORI, one of the most remarkable individuals of the sixteenth century, and the greatest king that Poland ever had. He was born in 1533, at Shomlo in Hungary, of an old and noble family of that country. The agitated state in which his native land continued during the sixteenth century, being torn by domestic factions, and troubled by the Turks and the Austrians, presented a vast field for the display of great talents, united to a daring and adventurous character, and Stephen Bathori rose after many vicissitudes to the sovereignty of Transylvania in 1571. In 1575 he was elected to the throne of Poland, vacant by the flight of Henry of Valois (Henri III. of France); and he owed this elevation to the renown of his valour and wisdom. He took possession of the crown; married, according to the conditions of his election, the princess Anna Jaguellon, sister to the deceased king Sigismund Augustus; repressed by his vigour the party which supported his competitor Maximilian of Austria; and pacified the country by conciliatory measures.

The true test of really great men is the ability of filling the shortest possible space of time with the largest amount of great deeds, and few characters in history may lay a better claim to having fulfilled these conditions than Stephen Bathori.

After having regulated the internal affairs of the country, he settled its foreign relations in a satisfactory manner, particularly by ensuring the friendship of the sultan of Turkey. He then turned his attention towards Muscovy. This power had recently obtained an extraordinary development under the celebrated Ivan Basilovich, who invaded a part of Livonia belonging to Poland shortly after the accession of Stephen. His first care was to organise a military force adequate to encounter such a formidable enemy, and to secure at the same time the tranquillity of the borders. He formed the Cossacks of the Ukraine into a regular force, allowing them the choice of their own hetman or supreme commander, and conferring on them many advantages as a reward for the services which they were obliged to perform. The castles were repaired and provided with permanent garrisons; a formidable ordnance was created; and a body of life-guards and a regular infantry were organised.

Having completed his military preparations, he took the field in the summer of 1579 with a numerous army composed of national troops, German mercenaries, and five thousand Hungarians, commanded by Bekesh. Bekesh, a countryman of Bathori, had been his enemy and competitor for the throne of Transylvania, but finally, struck with admiration of the superior qualities of Bathori, he disclaimed his enmity, and requested the honour of serving under his command. These sentiments were fully responded to by Bathori, who placed in his former enemy an unlimited confidence, which Bekesh justified by his services.

On commencing the campaign, Bathori issued a proclamation to the people of Muscovy, declaring that he was making war against their tyrannical sovereign, and not against them, and promising protection to their lives and property. The Russian historians bear evidence that this promise was strictly fulfilled, and that this campaign was free from all those atrocities by which war was usually accompanied in those times. The Muscovites were defeated in several battles. Polotzk was taken after a desperate resistance; but the garrison and inhabitants were spared by the conqueror, who immediately granted to the town the liberties enjoyed by the cities of Poland, and the same privileges and security to the Greek church which it had enjoyed under the dominion of Moscow. Having restored that important place to Poland, from which it had been taken several years before, he obtained some other advantages during the same campaign, and returned in the winter to Warsaw to attend the diet, which received him with great enthusiasm, and willingly granted the necessary means for the continuation of the war. Bathori resumed it with great vigour in the summer of 1580; the town of Veliki Luki and several others were taken: and in the next year, 1581, the city of Plescow was besieged by Zamoyski, one of the greatest statesmen and warriors that Poland had

produced [ZAMOYSKI], and to whom Bathori had entrusted the command of the army. The progress of the Polish arms was arrested, and the fruits of so many triumphs were destroyed, by the intrigue of the Jesuit Possevinus, who, deceived by the promises of the czar Ivan Basilovich to acknowledge the supremacy of the pope, induced Stephen Bathori to conclude peace with Muscovy on the 6th January, 1582, by which the Polish conquests were restored to the czar, with the exception of Polotzk and a few other towns and castles. Bathori employed the interval of peace in introducing different improvements, and was making preparations for another war with Muscovy, the dangers of which his policy could easily foresee. The pope, Sixtus V., deceived by the czar, who as soon as the danger was over thought no more about submitting to Rome, granted the Polish king a considerable subsidy. The projects of Bathori against Muscovy, which are supposed to have had for their object a change in the form of the government of that country, were cut short by his death, after a short illness at Grodno, on the 12th December, 1586, at the age of fifty-four.

The wars in which he was engaged did not prevent him from paying due attention to the civil affairs of the country, in which the following improvements were introduced during his reign. The province of Mazovia, which had hitherto been governed by a separate code, was induced by Stephen to adopt the general laws of Poland, with some few exceptions. The statute-book of Lithuania was enlarged by the addition of many new articles. The statute of Culm, by which the towns of Prussia were governed, was revised. Many salutary laws respecting the property of the crown and the privileges of the nobles were enacted. But the most important civil act of this king was the establishment of tribunals or supreme courts of justice for Poland and Lithuania. They were composed of members elected for the session by the same voters who returned the nuncios, or members of the diet. This institution, which supplanted the administration of justice by the king, and rendered it independent of the crown, continued till the dissolution of Poland. [POLAND, *Constitution of*.]

Stephen Bathori was very fond of learning and a great patron of learned men. In his early life he was imprisoned for two years in a fortress, by the emperor of Austria, which time he spent in the study of the classics, and particularly in that of the 'Commentaries' of Cæsar, which he is said to have known by heart. He is supposed to have been originally a Protestant, but to have been induced by the representations of a Roman Catholic bishop to abjure secretly his creed and to become a Roman Catholic on his accession to the crown of Poland, so that many believe that he had always conformed to the Roman Catholic church. Some learned Jesuits having gained his confidence, he became a great patron of their order, and founded for them the university of Wilna and the college of Polotzk, which he richly endowed. He was however strongly opposed to religious intolerance, and maintained evenhanded justice amongst the various denominations which prevailed in Poland. He was of a generous and forgiving disposition, as an instance of which we may quote the following anecdote:—A noble called Penkoslawski, who was a very gallant officer, violently opposed the king as a nuncio at a diet. It happened that just at that time the grant of an estate was to be made, and Stephen gave it immediately to Penkoslawski, saying, 'He is as good a soldier as he is a bad nuncio.'

He left no issue, and resigned, on his election to the throne of Poland, the principality of Transylvania to his brother Sigismund.

As a proof of his tolerant spirit and enlightened mind, we may adduce his favourite saying—'that God has reserved three things to himself; the creation of something out of nothing, the knowledge of futurity, and the government of the conscience.'

STEPHENS (French, **ETIENNE** or **ESTIENNE**; Lat., **STEPHANUS**) is the name of a family of the most illustrious scholars and printers that has ever appeared. Several of the members of this family bore the same Christian name, which has produced much confusion in the accounts that have been given of them. We shall give the lives of them in a chronological succession, and distinguish those of the same name by the epithets the first, the second, &c. The earliest among them who distinguished himself is—

HENRY STEPHENS I., who was born at Paris; the year of his birth is uncertain, though it is generally supposed that it was about 1470. He had his printing establishment at Paris, in a place which he calls 'e regione scholæ decretorum,' which is now called 'Rue de l'Ecole de Droit.' The earliest work which is said to have been printed by him is of the year 1502, the year before that in which his son Robert was born. The works which he printed were mostly on theological, philosophical, mathematical, and medical subjects, and he published very few editions of the classical writers. On the title-page of his publications are represented two men looking at a shield which stands between them, and contains three lilies, and above them a hand holding a closed book. Above the heads of the two men is the device—'Plus olei quam vini.' At the bottom of the title-page he sometimes gives only his initials, H. S., and sometimes his full name. All the works that came from his press were very correctly printed, as he always revised the proofs. A list of his publications is given by Maittaire (*Historia Stephanorum*, ii. 1, p. 1-9, and by Renouard, vol. i.). from which we extract the following:—In 1512 he published the 'Itinerarium Antonini;' in 1519 the works of Dionysius Areopagita; in 1521 an extract of the 'Arithmetica' of Boethius. In 1522 his son Robert was engaged in the printing establishment of his father-in-law Simon de Colines, who calls himself the successor of Henry Stephens, and married his widow. From this fact we must infer that Henry Stephens died in 1521 or 1522. He left three sons, Francis, Robert, and Charles.

FRANCIS STEPHENS I., was the eldest of the three sons of Henry Stephens. He was a partner of Simon de Colines: there are very few books known to be printed by him. The earliest is a work called 'Vinetum,' printed in 1537. In 1543 he published a 'Psalterium Græcum,' in 16mo., in which the titles and the initials of the verses are printed in red. The last of his publications is the 'Andria' of Terence, in 8vo. His mark on the title-page is a tripod, which stands upon a book, and from which a vine-branch rises. The device upon the base is—πλέον ἐλαίου ἢ οἴνου, with the Latin translation, 'Plus olei quam vini.' The year of his birth as well as of his death are unknown. A list of his publications is given by Maittaire, p. 31, and by Renouard, vol. i.

ROBERT STEPHENS I., the second son of Henry Stephens I., was born at Paris in 1503. In his youth he studied the Latin, Greek, and Hebrew languages, and he made such progress, that at an early period of his life he gave most extraordinary proofs of his learning, and was subsequently placed by his contemporaries above the greatest scholars that had ever lived. After the death of his father, he was for some time engaged in the printing-office of Simon de Colines, his father-in-law, and he appears, as early as his nineteenth year, to have had the entire management of the printing, correcting, and editing of several works, for in 1522 there appeared from the establishment of De Colines an edition of the New Testament (*Novum Testamentum, Latinè*, in 16mo.), which, although a copy of the Vulgate, was more correctly printed than any previous edition, and also contained some corrections by Robert Stephens. The professors of the Sorbonne, alarmed at the appearance of a new edition of a book which they wished to keep from the public, especially at a time when Protestantism was making rapid progress, inveighed in their lectures against the audacious youth, and declared that the book should be burnt. But their anger produced little effect. A short time after this he married Petronella, a daughter of the celebrated scholar and printer Jodocus Badius, a woman of great talents, who understood and spoke Latin as well as her mother-tongue. As the house of Stephens was visited by scholars and eminent men of all countries, Latin became the ordinary language of conversation; and it is said that the children and even the servants acquired some facility in speaking it. After his marriage he established a separate printing-office for himself, though he remained in the same street in which his father's office was situated. The earliest publication from his own establishment was 'Apuleii Liber de Deo Socratis,' 1525, 8vo. Others believe that he had no separate establishment till two years later, and that Cicero's 'Partitiones Oratoriæ' and 'Persii Satyræ' (1527) were the first works that issued from it. These works were followed by a great number of Roman authors, and Latin translations from the Greek and other languages, some of which were made by himself. For many years scarcely a month passed without some new publication, and if we recollect that in most of the works he acted as editor, and

corrected the proofs with the most anxious care, it appears marvellous that so many works could be produced in so short a time; the mere list of his publications in Maittaire, from 1527 till 1560, which is not by any means complete, fills twenty large octavo pages (p. 10-30). His device on the title-page of his publications was an olive-tree with one or more branches broken off, while new branches are engrafted on the tree, and the motto was 'Noli altum sapere,' to which he sometimes added 'sed time.' Until the year 1532 he used the same types as his father, but in this year he used a larger and more elegant type for his 'Biblia Latina,' of which he had published the first edition in 1528, under the title 'Biblia utriusque Testamenti Latina, ex veteribus MSS. exemplaribus emendata,' fol. This edition was not only in appearance the finest that had ever been printed, but that he might be able to give the text with the utmost correctness, he had examined all the libraries of Paris, St. Germain, St. Denis, and had got over from Spain at his own expense a very valuable Spanish Bible.

In the year 1531 Stephens published his first great original work: 'Dictionarium, seu Latinae Linguae Thesaurus,' fol. The second (1536) and the third or last edition (1545) of this dictionary are in two volumes, folio, and contain numerous corrections and improvements by Robert Stephens. The work has often been reprinted in other countries.

In the year 1539 Stephens was appointed printer to the king of France for Latin and Hebrew works, and henceforth he always added on the title-page of his publications, to his name, Regius Typographus, or Regius Librarius, or some other similar title. Soon after this honour was conferred upon him he received the same distinction for Greek works, whence he calls himself sometimes 'Regius Typographus in Graecis.' Stephens appears to have thought that he ought to produce his publications in a form worthy of his new rank, and it was on his suggestion that Francis I. had new Hebrew, Greek, and Roman types made by Claude Garamond. These types, which were of exquisite beauty, were afterwards known under the name of Characteres Regii. In 1540 Stephens published a new edition of the Latin Bible with various readings. On its appearance the divines of the Sorbonne renewed their attacks, but owing to the king's liberal protection he was enabled to continue his labours unmolested. The king had such a high esteem for his learned printer, that he frequently visited him in his office, and on one occasion, when he found him correcting a proof sheet, he stopped behind him and waited silently till Stephens had finished his task, before he began to conver with him. The first Greek book that Stephens printed in the capacity of Regius Typographus in Graecis, belongs to the same year, 1540, and bears the title Γνῶμαι Μονόστιχοι, sive Sententiae singulis versibus contentae juxta ordinem Literarum ex diversis Poetis, cum Interpret. Latina.' In 1543 he published a little work called 'Alphabetum Graecum,' which only contained sixteen leaves, and was afterwards frequently reprinted. This is supposed to be the first book that was printed with the Characteres Regii. In the following year Stephens edited, in one folio volume, a collection of the most eminent Greek ecclesiastical historians, under the title 'Ecclesiastica Historia Eusebii, Socratis, Theodoriti, Theodori, Sozomeni, Evagrii, Graece.' This work was soon followed by 'Eusebii Praeparatio Evangelica' in Greek. These two volumes contain the earliest specimens of the device subsequently adopted by all royal printers: a thyrsus with an olive branch and a serpent wound round it, and the motto, βασιλεῖ τ' ἀγαθῷ κρατερῷ τ' αἰχμητῇ. In 1545 he published a new edition of the Latin Bible, which he had been preparing for several years. It contains notes which are ascribed to Vatablus, and which are said to have been communicated to Stephens by the pupils of this theologian. But the authorship of the notes is a point which, even at the time, appears to have been the subject of much dispute. In the year following he published his first Hebrew Bible, and also a new edition of the Latin Bible in folio, with a preface which shows the immense pains that he took to give the text as correctly as possible.

These repeated editions of the Bible and the notes ascribed to Vatablus, which were in some parts supposed to savour of the reformed doctrines, to which Stephens himself was attached, involved him again in disputes with the professors of the Sorbonne. He offered publicly to acknowledge any errors which he might have committed, and to print them in an appendix to his Bible, to guard the readers against them. The king several times required the professors to draw up a list of the errors or heresies, but they never did it. Their object was not to prevent the propagation of any particular errors, but to get the Bible and the commentary put into the Catalogus Librorum Prohibitorum, and thus to stop its sale altogether. The matter was constantly deferred, and all attempts to bring it to a close were fruitless. Stephens, in the meantime, regardless of the clouds which were gathering over his head, continued as active as ever. In 1547 he published the Editio princeps of the 'Antiquitates Romanae' of Dionysius of Halicarnassus, which is still highly valued as a very beautiful and correct edition. It was soon followed by the Editio princeps of Dionysius of Alexandria 'De Situ Orbis,' with the Greek scholia of Eustathius.

In this year (1547) king Francis I. died, and Stephens lost his greatest patron and protector. His successor, Henry II., was at first favourable to Stephens, and required the divines of the Sorbonne speedily to produce their 'censurae,' threatening to punish them if they made any further delay. The professors, who knew the vacillating and weak character of the king, promised obedience, but nothing was done, and new charges were brought against Stephens, and new attempts were made to suspend the sale of his Bible. At last it was agreed that Stephens and the learned divines should meet at the king's palace at Fontainebleau, where several bishops and cardinals likewise appeared. Stephens was acquitted of the charge of having printed anything that impugned the Roman Catholic faith. The divines, thus disappointed, suddenly contrived to give another turn to the matter, and to get an order from the king for a temporary suspension of the sale of Stephens's Bible, and for the matter to be investigated afresh by a commission, whose duty it was to take cognizance of cases of heresy. After eight tedious months, Stephens at last obtained from the king another order, that his case should be tried by the king's privy council only. When Stephens had thus, for a time at least, secured his tranquillity, he produced, in 1548, the Editio princeps of Dion Cassius, libri xxiii., and several other works. In this year he had occasion to travel to Lyon, and in this journey he is said to have made the subdivision of the chapters of the Bible into verses, which was subsequently adopted in nearly all editions of the Scriptures. King Henry II. happened to be at Lyon, and when Stephens, availing himself of the opportunity, presented himself before the king, and at the same time thanked Cardinal de Guise for the services he had done him, Stephens was informed, to his utter astonishment, that a change had taken place in the king's mind, in which he could not mistake the secret and intriguing workings of his adversaries: the sale of his Bibles was prohibited. Stephens, indignant at such proceedings, declared that he would leave his country; but the king requested him to retain his office of royal printer, and promised that the matter complained of (the censuræ) should be speedily produced.

Stephens was persuaded to remain; but, owing to the king's vacillation, he was still subjected to various disappointments and vexations. Some of his biographers state that in this year he visited Zürich and Geneva; and if this be true, he perhaps undertook this journey with a feeling that it would soon be necessary for him to seek a refuge in a foreign country. In 1550 he published his beautiful edition of the Greek Testament, with a 'nova translatio Latina.' Stephens presented this work to bishop Du Chastel, who had hitherto pretended to be his friend, but who now courted the favour of the Sorbonne, and declared that every sort of protection which he had formerly given to Stephens had arisen from his not knowing the real character of his offences. Hereupon the Sorbonne again began to annoy Stephens; and after a tedious and ludicrous trial, held by men who found fault with the various readings in the margin of Stephens's Bible, which they took to be an heretical commentary, he was forbidden to sell his impressions of the Bible, and commanded to promise that he would print no more copies of the Scriptures without the sanction of those learned divines.

Stephens was now convinced that no reliance could be placed either on the king, his counsellors, or the great prelates, and that he must be prepared for the worst. He however made preparations for a step which his enemies did not expect. He finished the numerous works which were at the time going through the press, and at the end of the year 1551, or at the beginning of 1552, he escaped with

his family to Geneva, where he hoped to find that liberty of conscience which he had so long wished for. Stephens is charged by some writers with having taken with him some of the materials belonging to the royal printing establishment, but his biographers have shown that there is not a shadow of ground for this charge. There is also a tradition, which does not seem at all improbable, that the professors of the Sorbonne vented their impotent rage by burning Stephens in effigy.

Stephens began his new career at Geneva with the publication of some books of the Old Testament, and of the whole of the New-Testament in Latin and French. In 1552 he also published 'Ad Censuras Theologorum Parisiensium, quibus Biblia à Roberto Stephano, typographo regio, excusa calumniose notarunt, eiusdem Roberti Stephani responsio.' This book, which was also published in French, gives us a clear insight into the nature of his disputes with the Sorbonne, as well as into his own character. The other works which he published during a period of seven years at Geneva are almost exclusively of a theological and controversial nature, consisting of works written by Calvin, Beza, and other distinguished reformers. He retained his former device, but under it he printed, 'Oliva Roberti Stephani.' The name of Geneva seldom appears on the title-page of his books. He died on the 13th of September, 1559, leaving behind him, it is said, a numerous offspring and considerable property. But only three of his sons are known, Robert II., Henry II., Francis II., and a daughter of the name of Catherine.

There is perhaps no man in modern times to whom literature and learning are more indebted than to Robert Stephens. His unbiassed contemporaries not only place him on a level with the greatest scholars, but declare that he excelled them all.

Charles Stephens appears to have been about a year younger than his brother Robert. His education was sound and classical; but he also applied himself to the physical sciences, and took his degree of doctor of medicine, which he practised for some time. He wrote several treatises on subjects connected with medicine, natural history, and agriculture, which however are less scientific than historical, for he treated his subjects chiefly in relation to antiquity. His earliest productions are abridgements of works by Lazarus Baifius, such as 'De Re Vestiaria;' 'De Vasculis;' and 'De Re Navali,' which were published by Robert Stephens (1535 and 1537). Lazarus Baifius (Lazare Baif) engaged Charles Stephens as tutor to his son, and in 1540 took him with his son to Germany, and afterwards to Italy, to which countries he was sent as ambassador of the king of France. In Italy Stephens became acquainted with Paulus Manutius, who in one of his letters (v. 17) speaks of him in high terms. On his return to Paris he appears to have continued the practice of medicine, but in 1551, when Robert removed to Geneva, the whole of his printing establishment, with the exception perhaps of the department for printing Hebrew, which appears to have been undertaken by Martinus Juvenis, passed into the hands of Charles Stephens, for the Editio princeps of 'Appiani Alexandrini Historiarum Romanarum Celtica, Libyca vel Carthaginiensis, Illyrica, Syriaca, Parthica, Mithridatica, Civilis quinque libris distincta,' which appeared at Paris in 1551, 'Cura ac Diligentia Caroli Stephani,' is probably the first book which he printed, though it had been prepared or commenced by Robert Stephens. It is a beautiful specimen of typography. There is a French translation of a treatise of Plutarch, called 'Traicté sur la Honte vicieuse,' by F. Legrand, which is by some referred to the year 1544, and is supposed to be the first book printed by Charles Stephens; but it probably belongs to the year 1554. Soon after Robert left Paris, Charles appears to have been appointed Royal Printer, for this title is mentioned on his last two publications of the year 1551. Henceforth he continued to be very active in his new sphere till the year 1561, for in these ten years there issued from his press 97 works, on a great variety of subjects, some of which he had written himself. Charles Stephens seems to have been a man who knew something of everything, but nothing very well. His character as a man has been attacked in a letter of Maumontius addressed to J. Scaliger, in which he is called a 'malus' and a 'male volens homo,' and is charged with unkind conduct towards his nephews, the sons of Robert. But as we hear of no accusations of this kind from any other quarter, the impartiality of the writer may be doubted. Charles Stephens died in the year 1564. Some say that he was persecuted for his religious opinions, and died in prison; others state that he was imprisoned for debt in the Châtelet, and that he remained there for the last three years of his life. It may be that both causes combined to bring this misery upon him; for we know that he lost a great deal of his capital in 1557, by the publication of his 'Thesaurus Ciceronianus,' which was a very expensive undertaking, and did not sell. It is also certain that during the last three years of his life no work appeared from his press. He left one daughter of the name of Nicole, who was no less celebrated for her beauty than for her talents and accomplishments.

Lists of the works which were written or printed by Charles Stephens are given by Maittaire and Renouard. We shall only mention the principal: 'De diversis Regulis Juris antiqui, Pandectarum libri quinquagesimi titulus xvii. et ultimus,' &c., Lutetiæ, 1552, reprinted in 1557; 'Dictionarium Latino-Gallicum, postrema hac editione valde locupletatum,' 1552, reprinted in 1570, fol.; 'Dictionarium Historicum ac Poeticum, omnia gentium, hominum, locorum, fluminum, ac montium, antiqua recentioraque, ad sacras ac profanas historias poetarumque fabulas intelligendas necessaria vocabula bono ordine complectens, cura ac diligentia C. Stephani,' Lutetiæ, 1553, 4to.; 'Philonis Judæi, de divinis decem Oraculis liber, Johanne Vacuræo interprete,' 1554, 8vo.; 'Prædium Rusticum, in quo cujusuis soli vel culti vel inculti plantarum vocabula ac descriptiones, earumque conserendarum atque excolendarum instrumenta suo ordine describuntur, &c.,' auctore C. Stephano, 1554, 8vo. This work has been translated into French, Italian, German, English, and Dutch. 'De Latinis et Græcis Nominibus Arborum, Fruticum, Herbarum, Piscium, et Avium, Liber; ex Aristotele, Theophrasto, &c., cum Gallica eorum nominum appellatione,' quarta edit., 1554; 'Latinæ Linguæ cum Græcâ Collatio ex Prisciano et probatissimis quibusque Authoribus per locos communes literarum, partium orationis, constructionis ac totius Grammatices,' auctore C. Stephano, 1554, 8vo.; 'Dictionarium Latino-Græcum, in quo singulæ Dictiones ac Locutiones Latinæ Græcis vocibus ac sententiis Præmissæ magnum utriusque linguæ commercium indicant,' &c., Parisiis, 1554, 4to.; 'M. Tullii Ciceronis Opera,' Paris, 1555, 4 vols. fol.; Caroli Stephani 'Thesaurus Ciceronianus,' Par., 1557. Stephens also compiled a 'Dictionarium Historico-Geographico-Poeticum,' which was printed after his death at Geneva in 1566, 4to., and was afterwards often reprinted in folio. N. Lloyd edited in 1670 an edition of it at Oxford, and in 1686 another was published in London. All the works of C. Stephens are very beautifully printed.

Henry Stephens II., the greatest of the whole family, was the son of Robert and grandson of Henry. He was born at Paris in 1528. Even as a child he showed most extraordinary talents. The numerous engagements of his father did not allow him to spend much time upon the education of the boy; but he carefully watched and regulated it. Latin he learnt naturally, as it was constantly spoken in the family, but before he seriously studied it the father made him learn Greek. He received his first instruction in Greek from a schoolmaster, who while reading the 'Medea' of Euripides with his boys, made it the practice to assign a part to each of them; and as soon as Henry had made sufficient progress to join them, he read this play with the greatest avidity, and soon knew it all by heart. After he had spent some time at this school, he was instructed in Greek by Petrus Danesius, who was then, next to Budæus, perhaps the ablest Greek scholar of the time; and who, on account of his intimate friendship with Robert Stephens, took great interest in the progress of his pupil. At the age of about fifteen Henry also enjoyed the instruction of Jacobus Tusanus (Jacques Toussain); and subsequently, when this scholar died (1547), that of Adrianus Turnebus, who succeeded Tusanus in the professorship of Greek in the Royal College. Although he had been chiefly instructed in Greek by these men, he did not neglect Latin; for even when a boy he is said to have known by heart the first book of Horace's 'Epistles.' He also studied mathematics; and as soon as he heard something of astrology, he conceived a strong desire to become acquainted with it, and having met with a young friend who entertained the same wish, the two boys began to take lessons. Henry did this without the knowledge of his father; but as the fees were very high, and the father, who thought that his son was taking lessons in mathematics, did not pay more than was necessary for mathematical

lessons, the boy persuaded his mother to make up the deficiency. In this way he wasted much money and time, but he soon became aware of the futility of these pursuits, and gave them up altogether.

In the year 1546 Robert Stephens thought his son qualified to assist him in his printing establishment, and in this year Henry collated a MS. of Dionysius of Halicarnassus, whose works Robert was preparing for publication. In the year following, when the death of Francis I. deprived Robert of his chief patron, Henry undertook a journey to Italy, the main object of which was to search the libraries and examine the manuscripts in that country. Three years were spent in visiting the various places of Italy. In several towns his exertions were rewarded with discoveries; at Florence he found in a MS. of the Medicean library a number of Greek poems not known before, which were the 'Epitaphia Homericorum Heroum.' He afterwards printed them in his 'Florilegium Epigram. Græc.,' 1566, and also in his 'Homeri et Hesiodi Certamen,' 1573. At Naples and Venice he examined several MSS. At Rome he was very kindly received by Cardinal Sirlet, who communicated to him a MS. of Athenagoras, and corrections of several passages in Xenophon, of which he subsequently made use in his edition of Xenophon, 1561. It appears that during this journey he also made a collation of a MS. of Athenaeus in the Farnesian library, the various readings of which he communicated to I. Casaubon, who used them in his edition of Athenaeus (1597). At the same time he made the acquaintance of the most distinguished scholars of the age, such as Muretus, P. Manutius, C. Sigonius, P. Vettori, Cardinal Maffeo, and many others. On his return, in the year 1549, he brought with him the treasures which he had discovered and collected. This was just at the time when his father was finishing his folio edition of the Greek Testament, for which Henry wrote sixty Greek verses which were prefixed to it. About the same time he wrote notæ and argumenta for the edition of Horace, which Robert published in 1549. In 1550 Henry Stephens set out on a journey to England, where he was kindly received by Edward VI. His stay was not long, but he appears to have paid great attention to everything that came in his way, and turned it to good account. He himself mentions some interesting circumstances connected with his visit to England in his 'Apologia pro Herodoto,' and in the preface to his edition of the 'Poetæ Heroici Græci.' On his return from England he visited Flanders, Brabant, and the university of Louvain (Loewen). It was at Louvain, as it appears, that he met with a Greek Anthology in MS. which was in the possession of an Englishman of the name of John Clements. From this he copied some verses which were afterwards inserted in his 'Florilegium.' From the same Clements he obtained one of the two MSS. which he used in his Editio princeps of Anacreon. During his short stay in the Netherlands, he made himself master of the Spanish language. On his return to Paris towards the end of the year 1551 his father was preparing to quit France, and it is not improbable that Henry accompanied him to Geneva. This is however not quite certain, for in 1554 we find him at Paris, where he published the Editio princeps of Anacreon, in 4to., with a Latin translation and notes by himself. Whether at this time he had a printing establishment of his own, or whether he printed his book in that of his uncle Charles, is uncertain, although the latter is more probable, for in the same year he edited 'Dionysii Halicarnassei Responsio ad Cn. Pompeii Epistolam,' &c., the title-page of which expressly states that it was printed by Charles Stephens. The first indication of a printing establishment belonging to Henry Stephens occurs towards the end of the year 1556, when 'Davidis Psalmi aliquot Latino Carmine expressi à Quatuor Illustribus Poetis, quos Quatuor Regiones, Gallia, Italia, Germania, Scotia, genuerunt,' &c. appeared, with the addition, 'Ex officina Henrici Stephani.' Towards the end of the year 1554 he made a second journey to Italy, and discovered at Rome a considerable part of the historical work of Diodorus Siculus, which had not then been printed, and which he afterwards inserted in his edition of 1559. In 1555 he went from Rome to Naples in search of something which appears to have been of importance to the king of France, and to his ambassador at Venice, Odet de Selve, but it is not stated what the object of his search was. The circumstance that the king of France was then at war with the emperor Charles V. brought H. Stephens into great danger at Naples, for he was here discovered by some Italian who had met him at Venice in the house of the French ambassador, and when Stephens was on the point of being arrested, he only saved himself by insisting upon his being an Italian, and he spoke the language so well that the Italian was at last persuaded, and let him go. On his return to Venice he rendered an account of his mission to the ambassador, who was well pleased with the manner in which he had executed his instructions. At Venice Stephens made a collation of a MS. of Diogenes Laertius in the library of St. Mark, which had originally belonged to Cardinal Bessarion, and which he used for his edition of Diogenes of 1570. He also examined two MSS. of Xenophon, one of which he made use of in his edition of 1561.

During the year 1557, when Stephens was in the full possession of a printing establishment, he published seven new works, some of which had never been printed before: among them are the Editio princeps of 'Maximi Tyrii, Philosophi Platonici, Sermones, sive Disputationes XLI., Graece, nunc primum editæ,' with a Latin translation; Æschylus, with notes by P. Victorius and H. Stephens; 'Ex Ctesia, Agatharchide, Memnone excerptæ Historiæ; Appiani Iberica. Item, de Gestis Annibalis: Græce. Omnia nunc primum edita, cum H. Stephani Castigationibus;' and 'Ciceronianum Lexicon Græco-Latinum,' &c. Henry adopted the emblem (an olive-tree) and the device of his father, 'noli altum sapere,' to which is sometimes added, 'sed time.' Another device of his which sometimes occurs is, 'ut ego insererer, defracti sunt rami,' which contains an allusion to the branches which are represented as engrafted upon the olive-tree. The travels of Stephens and the printing of expensive books had embarrassed his affairs, and after the year 1557 he found himself in great difficulties, but he was assisted by Ulrich Fugger, a wealthy merchant of Augsburg, who, besides a large sum which he gave or advanced to him, gave him an annuity of 150 thalers. Stephens from gratitude for this munificent liberality, henceforth called himself Typographus Huldrici Fuggeri, or Fuggerorum Typographus, which appears on most of his publications down to the year 1568. The Fuggers assisted Stephens also in other respects; they had an excellent library and some valuable MSS., which they allowed him to use for his editions of antient works, as in that of 'Imperatorum Justiniani, Justini, Leonis, Novellæ Constitutiones,' &c., Graece, the only work that he edited in the year 1558. After a series of years the Augsburg merchants appear to have become tired of supporting the great printer. In a collection of letters of Stephens, published by Passow in 1830, there are some which show that Stephens wanted them to advance him a small sum of money which they had promised, and that at length after much correspondence they did not keep their promise. In consequence of this his connection with the Fuggers ceased in 1576.

In the year 1559 H. Stephens published his edition of Diodorus Siculus in fol., in which ten books of this historian were printed for the first time. The MS. which he used for this edition is now in the public library of Geneva. Other publications of this year are, Appian's 'Hispanica et Annibalica,' with a Latin translation by Beraldus, in 8vo., and 'Gentium et Familiarum Romanarum Stemmata,' &c., in fol. In this year his father Robert died at Geneva, and Henry was appointed executor of his will, in which he was also enjoined to take care of his brothers. Robert, one of his brothers, had been, as it appears, disinherited by the father because he would not abandon the Roman Catholic faith and follow his father to Geneva. Accordingly the printing establishment of Robert, the father, came into the hands of Henry, who continued to publish theological works and several editions of the Bible. H. Stephens appears now to have given up his establishment at Paris, and to have devoted himself to the management of that at Geneva.

In the year 1555 H. Stephens married for the first time, but in 1564 or 1565 he himself states that his wife died. He afterwards married again, for the letters published by Passow show that about the year 1581 he became a widower a second time. On his death in 1598, he left a wife surviving, from which it appears that he was married thrice. By his three wives he had altogether 14 children, ten of whom died at an early age.

In 1560 he published a collection of the lyric poets of Greece with a Latin translation in 16mo., which has been often reprinted. In the year following appeared his edition of Xenophon in fol., for which he had collated a great number of MSS., and to which he added a commentary and

a Latin translation. An improved edition was published in 1581. During the last two years H. Stephens was in bad health and subject to melancholy, arising from over-exertion and the heavy cares that devolved upon him after his father's death. In this state he scarcely worked at all; he almost conceived a disgust for literary occupations, and could not bear the sight of a book. But the renewed activity into which he was drawn unconsciously in 1562, restored him to health. The work which roused him to fresh exertion was a Latin translation of 'Sexti Philosophi Pyrrhoniarum Hypotyposeon Libri Tres.' The Greek original of this work was not printed until 1621. It must have been soon after his recovery that Stephens began his greatest work, the 'Thesaurus Linguæ Græcæ,' upon which he spent ten years. In 1564 he wrote and published a 'Dictionarium Medicum, vel Expositiones Vocum Græcarum Medicinalium, ad Verbum, excerptæ ex Hippocrate. Aretæo,' &c., cum Latina Interpretatione, in 8vo. In this work he received some assistance from J. M. Gesner; it was highly spoken of by contemporary scholars, with the exception of Jos. Scaliger, who censured it severely, but he appears to have had a personal pique against Stephens. In this year Stephens edited a still-useful collection of 'Fragmenta Poetarum Latinorum, quorum Opera non extant,' &c., in 8vo., and an edition of Thucydides with the Scholia, and a Latin translation by L. Valla. In 1566 he published, among other books, his 'Florilegium' of Greek Epigrams; 'Poetæ Græci Principes Heroici Carminis et alii nonnulli,' &c., in fol., which is most beautifully printed, and his edition of Herodotus with Valla's translation and his own 'Apologia pro Herodoto,' which he himself afterwards translated into French. Passing over a great number of valuable publications which appeared from 1566 till 1572, we proceed to the year 1572, in which the Greek Thesaurus was published under the title 'Thesaurus Græcæ Linguæ ab Henrico Stephano constructus. In quo præter alia plurima quæ primus præstitit (paternæ in Thesauro Latino Diligentiæ æmulus) Vocabula in certas Classes distribuit, multiplici Derivationum Serie ad Primigenia tanquam ad Radices unde pullulant revocata,' with the appendix and index, 5 vols. fol. This work made an epoch in the history of Greek philology, as well as in the life of the author, who had embarked in it nearly all his property. The price of this prodigious work was necessarily high, and accordingly it could not have many purchasers. When Scapula some years afterwards published his cheap abridgement [SCAPULA], the sale was nearly stopped, and Stephens became involved in great difficulties. It has been supposed by some that Stephens soon after published a second edition of his Thesaurus, but this opinion has merely arisen from the fact that he cancelled a number of pages of the original edition, and inserted new ones in their place. In 1745 Daniel Scott published, in 2 vols. fol., 'Appendix ad Thesaurum ab H. Stephano constructum.' A new edition of the Thesaurus was published in London (1815-1828) in 7 vols. fol., with numerous additions by Barker, which however have not increased the value of the book. A new edition is now in course of publication at Paris, which is edited by Hase, and L. and W. Dindorf.

It appears to have been owing to the pecuniary difficulties in which Stephens was involved after the publication of his Thesaurus, that, in order to divert his mind, he made various excursions in France and Germany, but he always took the opportunity of exploring libraries and comparing MSS., and thus collected vast quantities of materials for works which he was publishing or projecting. In 1573 he published an edition of all the extant works of M. Terentius Varro in 8vo., and a collection of the fragments of the philosophical poets of Greece. The year following he produced an excellent edition of Apollonius Rhodius with the antient scholia and a commentary by himself. In 1575 there appeared his collection of the Greek orators, some of which are accompanied by a Latin translation; and Arrian's 'Expeditio Alexandri Magni,' &c. with a Latin translation. In 1577 he published, among other books, an edition of Cicero's 'Epistolæ ad Familiares,' in 2 vols. 8vo.; the second volume contains the commentaries of P. Manutius, Lambinus, Sigonius, Camer, and of Stephens himself. In the year 1578 he brought out his magnificent edition of Plato's works, in 3 vols. fol.; and in the same year he wrote a little French work, 'Deux Dialogues du Nouveau Langage François, Italianizé et autrement desguizé, principalement entre les Courtisans de ce Temps,' &c. (printed without name and date). This was an attack upon the fashion, very common at the time, of introducing Italian words into French. Stephens, after the MS. had received the 'imprimatur' from the state council of Geneva, had taken the liberty of making some additions, for which he was severely reprimanded by the council. Not thinking himself quite safe, or wishing to escape the annoyance to which this affair subjected him, he went, towards the end of 1578, to Paris, where he remained during the whole of 1579. Henry III. received him very kindly, and interested himself so much on Stephens's behalf, that he demanded of the council of Geneva permission for Stephens to return, and to clear himself from the charges which were brought against him. Stephens returned to Geneva, and was placed at the bar of the consistory, where he was treated with rigour and harshness, and for some days was put into prison. When Stephens at last owned that he had acted wrong, he was set at liberty.

During the stay which H. Stephens had made at Paris in 1579, he had a conversation with the king, in which he expatiated very ingeniously on the superiority of the French language over other modern tongues; and the king, delighted with this eulogy on the French language persuaded him to write a book on the subject. This book was published in the course of the same year, 'De la Precellence du Langage François,' Paris, 1579, 8vo. The king, pleased with the performance, ordered 3000 francs to be paid to Stephens from the public treasury, and also granted him an annual pension of 300 francs; but from the manner in which Stephens (in his 'Musa Principum Monitrix') speaks of this affair, it appears that he never received anything at all, for the treasurer at that time was a person of much more consequence in such matters than the king.

In 1581 Stephens published 'Juris Civilis Fontes et Rivi,' &c., in 8vo.; and, as is commonly supposed, also 'Sigonii Fasti Consulares.' The latter he printed without the sanction of the Council of Geneva, and was in consequence fined 25 thalers. This edition of the 'Fasti' of Sigonius, if it was really published by Stephens, must have been suppressed, for there is no trace of it now. H. Stephens spent the year 1585 again at Paris, where he published an excellent edition of A. Gellius and of Macrobius, both in 8vo. The former is preceded by a very interesting letter to his son Paul, from which, besides many other things, we learn that about this time his country-house had been destroyed by an earthquake, a loss which he bore with stoical indifference. In 1588 he published an edition of the Iliad and Odyssey, with a Latin translation.

During the time that Stephens enjoyed the friendship of the king of France, he spent a great part of his time at Paris. His publications during this period greatly decreased in number, and some of them were executed by Paris printers. His own establishment at Geneva was neglected. He was constantly travelling about, and he published his works wherever he happened to be, as at Paris, Frankfort, Basel, &c. From this fact it has been erroneously supposed that he had separate printing establishments in these places. He often resolved to give up this wandering life, and was seriously exhorted by his friends to attend to his business; but the charms of a court life and the habit of travelling had now become strong, and he was dazzled by splendour and deceived by the hopes which he placed in the great. The years 1588 and 1589 he appears however to have spent at Geneva, and several works again issued from his press; but in 1590 no work came out at Geneva, and only one ('Principum Monitrix Musa') at Frankfort, where he appears to have spent some time. In this year Henry III. of France was murdered. The affairs of Stephens now grew worse and worse: his warehouses were full of books which he could not sell. In the year 1597 he left Geneva for France. He first stayed for some time at Montpellier, where Florence, one of his daughters, resided, who was married to Isaac Casaubon. Casaubon was just preparing his edition of Athenæus, and Stephens offered his assistance, which was refused. He then proceeded through various other places to Lyon, where he was taken ill; and feeling solitary and forlorn, and having no friends there, he was carried to a public hospital, where he died, in the beginning of March, 1598, at the age of nearly seventy years. Some writers say that he died out of his mind, a statement which, if true, can only apply to the last few days of his life. It is a mistake to suppose that Stephens died in poverty because he died in an hospital; for the proceeds of his books alone,

which were publicly sold and fetched low prices, were sufficient to pay his creditors, and to leave something for his wife and children. Stephens died without a will; and Casaubon, who went to Geneva to receive his wife's dowry, which was still owing, together with her share of the inheritance, was generous enough to leave Henry's library, MSS., and printing establishment, in the hands of his son Paul.

There is no scholar to whom the Greek language and literature is under greater obligations than it is to Henry Stephens. He knew his superiority, and sometimes showed that he felt it. The number of books which he printed, edited, or wrote, is immense; and it is truly astonishing that, even during the rambling life of his latter years, he was continually producing new works. During the earlier part of his life he was a man of inflexible resolution, and never rested till he had effected his purpose; and he was always planning something, even to the last days of his life. He has often been censured for his alteration of passages in antient writers without being supported by the authority of MSS., and without even assigning a reason for his alterations. This has been said more especially in regard to his edition of Plutarch, which came out in the same year that he published his Thesaurus; but Wyttenbach, on examining several MSS. for his own edition, found that H. Stephens was in most cases supported by MS. authority.

Robert Stephens II., the youngest son of Robert Stephens I., and brother of Henry Stephens II., was born at Paris in 1530. The first time that we find him taking part in the publication of a work was in 1556, when he and Morel, who was then royal printer, published the edition of Anacreon prepared by H. Stephens. The title of royal printer was conferred upon Robert in 1561, as appears from some books printed by him in this year, at the same time that he came into possession of the printing-office of Charles Stephens. In this office he continued till his death. In activity and accurate and beautiful printing he was worthy of his father, but this is all that we know of him. As royal printer he was much employed in printing edicts and ordonnances, as may be seen from the list of his publications by Renouard. He died in 1571. Among his publications we only mention the following: a reprint of the Historical Dictionary ('Dictionarium Propriorum Nominum Virorum, Mulierum, Populorum, &c.') of Charles Stephens, 1560, 4to.; 'Josephi Scaligeri Conjectanea in M. Terent. Varronem,' 1565; and several editions of Donatus 'De Partibus Orationis.'

After his death his wife married again, and kept up the printing establishment. There are publications down to the year 1588, 'Ex officina Roberti Stephani.'

Robert Stephens III., son of Robert Stephens II, was educated by the poet and abbé Desportes, who inspired him with a love for poetry, and with whom he appears to have stayed at least till 1584. He did not commence printing till 1606, so that eighteen years elapsed without a publication appearing from the press of Robert Stephens. His first publication was, 'D. Gregorii Nysseni ad Eustathiam, Ambrosiam, Basilissam, Epistola, Græce. I. Casaubonus nunc primum publicavit, Latine vertit et notis illustravit,' Lutetiæ, 1606, 8vo. He probably worked in the printing establishment which had belonged to his father, and continued to print until 1631. He distinguished himself also by his Latin, Greek, and French verses, and by a French translation of the first two books of Aristotle's 'Rhetoric,' which was printed in 1630, 8vo. In his publications he generally added to his name the letters R. F. R. N., that is, Roberti Filius, Roberti Nepos, to distinguish himself from his father and grandfather. He printed a great number of books: the principal are, 'Menandri et Philistionis Sententiæ Comparatæ, Græce, ex Bibliotheca Regia; cum notis, cura N. Rigaltii,' Lutetiæ, 1613, 8vo.; 'D. Junii Juvenalis Satyrarum Libri v., Sulpiciæ Satyra, Cura Rigaltii, &c.,' Lutet., 1616; 'Dictys Cretensis, De Bello Trojano, et Dares Phrygius De Excidio Trojæ,' &c., 1618, 16mo.

There are several other members of the Stephens family of the name of Robert, but none of them were distinguished. During the last century there was a French writer of the name of Robert Stephens (Robert Etienne), who claimed a descent from the illustrious family of printers.

Paul Stephens, a son of Henry Stephens II., by his second wife, was born at Geneva in 1566. He received his early education at home, and was then sent out by his father to visit the principal towns of Europe, and the distinguished scholars with whom his father was acquainted. Lipsius, whom he visited at Leyden, was much pleased with him, and in one of his letters calls him 'mitis adolescens.' On his return to Geneva he assisted his father in printing and editing. He afterwards made several other journeys, partly perhaps in connection with the business of his father. In 1594 he spent some time in London, where, among other distinguished men, he made the acquaintance of John Castolius. In 1595 he was at Heidelberg, and in 1596 at Frankfort, where he stayed in the house of the jurist Dionysius Gothofredus. He had married in 1589. His first literary production was, 'Pauli Stephani Versiones Epigrammatum Graecorum Anthologiae, Latinis versibus,' Genevæ, 1593, 8vo. He was always fond of making Latin verses, but his poetry is stiff and unanimated. His best is perhaps the poem on the death of his father.

After the death of his father, when the affairs of the family were settled, and Casaubon had left Geneva, Paul was placed at the head of his father's printing establishment (1599), which he conducted with great energy. He first reprinted a number of classical authors which had been edited by his father, and were then out of print, such as Virgil, Horace, the letters of Pliny, and the Latin panegyrists and others. The two works which do him most credit are, 'Euripidis Tragœdiæ quae extant, cum Lat. Guil. Canteri Interpretatione,' &c., containing the Greek scholia and commentaries of several scholars, 1602, 2 vols. 4to.; and 'Sophoclis Tragœdiæ Septem, unà cum omnibus Græcis Scholiis et Latina Viti Windemii ad verbum Interpretatione,' &c., likewise containing the Scholia, and also notes by H. Stephens. In 1619 he printed a folio edition of Herodotus, founded upon that of his father, with a Latin translation and notes by Sylburg. No other publication issued from his press till 1626, when he published a fifth edition of the lyric Greek poets: 'Pindari et cæterorum Octo Lyricorum Carmina.' This was his last publication. The inactivity in his establishment during the last years appears to have been the consequence of his want of capital, to which we may perhaps also attribute the fact that most of his works are printed on very bad paper. In 1626 or 1627 he sold his whole establishment to the brothers Clouet. It is not known what became of him after this, and the time of his death is also unknown. He had eight children, two of whom only, Anthony and Joseph, survived their father.

Francis Stephens II., son of Robert Stephens I., and an elder brother of Henry Stephens II., followed his father to Geneva, and is said to have been a good Greek and Latin scholar. After the death of his father he established at Geneva a printing-office of his own, which he conducted from 1562 to 1582, with an interruption however of nearly ten years. Even during the remaining ten years he printed very few books, and most of them for publishers: this appears to have been owing to his want of capital. The first work, and almost the only one that he printed on his own account, was Calvin's 'Commentaries on the Psalms,' 1563, fol. His last publication was Amyot's French translation of the 'Moralia' of Plutarch, 1581-2, 2 vols. fol. After this time he gave up printing and settled in Normandy, and we hear no more about him.

Anthony Stephens, son of Paul Stephens, was born at Geneva in 1592. He studied at Lyon, and afterwards finished his education at Paris, where he abjured Protestantism before Cardinal du Perron. In 1612 he obtained letters patent of naturalization in France, and at the same time the office of huissier de l'assemblée du clergé, with a salary of 500 franks, which he held until the year 1635. Long before this time however he had been in the possession of a printing establishment. Some writers mention a work by Perron, which Anthony Stephens is said to have printed in 1605. But this cannot possibly be correct, as Anthony was then only thirteen years old. The earliest work which he printed belongs to the year 1613, and henceforth he conducted his establishment with an activity worthy of his great ancestors until the year 1664. He was also honoured with the title of royal printer, through the influence of Cardinal Perron, and he received a pension of 600 francs, but the time when he first received it is uncertain. The pension was stopped when Perron died, and Anthony after this was several times in great pecuniary difficulties. Among his numerous publications, which comprise all the works of Perron, there are several valuable editions of antient authors, such as Casaubon's edition of Strabo, 1620; of Plutarch's Works, with Xylander's translation, 1624, 2 vols. fol.; Leun-

clavius's edition of Xenophon, 1625; Aristotle's Works, 1629, 2 vols. fol.

For many years after the death of his patron Anthony was in very straitened circumstances, and was supported by his son Henry, who, from the year 1646, had a printing-office of his own, where, among other works, Montaigne's 'Essays' were printed. When this son died in 1661, and Anthony was deprived of his last and only support, he sank rapidly: he became infirm, and at last lost his sight. In this state he dragged on a wretched existence until the year 1674, when he died in the Hôtel-Dieu at Paris, at the age of 82. He had had six children, all of whom died before him.

Besides the members of the Stephens family, whom we have mentioned above, there are two more, who however were never engaged in printing. The one is Henry Stephens, a son of Robert Stephens II., who was treasurer of the royal palaces; the other likewise called Henry, and a son of the former, acquired some reputation as a poet, and also wrote some other works in French.

Respecting the lives of the Stephens, see Th. Jansonii ab Almeloveen, 'Dissertatio Epistolica de Vitis Stephanorum,' Amsterdam, 1685; Maittaire, 'Stephanorum Historia,' London, 1709, 2 vols in 4 parts, which contains a list, though not complete, of their publications; Greswell, 'A View of the early Parisian Greek Press, including the lives of the Stephani,' Oxford, 1833; Ant. Aug. Renouard, 'Annales de l'Imprimerie des Etienne, ou Histoire de la Famille des Etienne et de ses éditions,' Paris, 1837, 2 vols. 8vo. This last work contains in the first volume a very complete list of all the publications of the Stephens, and various interesting and important facts, derived from the public records of Paris and Geneva, which were unknown to former biographers.

STEPNEY. [MIDDLESEX.]

STEPNEY, GEORGE, descended from an antient family in Pembrokeshire, was born in the city of Westminster, in 1663. In 1676 he was sent to Westminster School, where he continued his studies till 1682, when he removed to Trinity College, Cambridge, where he distinguished himself in 1683 by a Latin ode on the marriage of the Princess Anne to Prince George of Denmark. He took the degree of M.A. in 1689. At Westminster he had formed a friendship with Charles Montague, afterwards earl of Halifax, which was continued at Cambridge. They came to London together, and were both introduced into public life by the earl of Dorset.

Stepney's life, which was short, was chiefly spent in diplomatic employments. In 1692 he was sent as envoy to the elector of Brandenburg; in 1693, to the emperor of Germany; in 1694, to the elector of Saxony. In 1695 he published a poem, dedicated to the memory of Queen Mary; in 1696 he went as envoy to the electors of Mentz and Cologne, and to the congress at Frankfort; in 1698 to Brandenburg, in 1699 to the king of Poland, in 1701 to the Emperor, and in 1706 to the States-General. He was made one of the Commissioners of Trade in 1697. He died at Chelsea in 1707, and was buried in Westminster Abbey.

Stepney's poems are few, and of little value. He was one of the 'eminent hands' who were united with Dryden in the translation of Juvenal in 1693. Johnson says "he is a very licentious translator, and does not recompense the neglect of his author by beauties of his own.'

(Johnson's *Lives of the Poets*; &c.)

STEPPES. [PLAINS.]

STERCORA'RIUS. [LARIDÆ, vol. xiii., p. 336.]

STERCU'LIA, a genus of plants which gives its name to the natural family of Sterculiaceæ, which sometimes forms a section of the family of Byttneriaceæ. The name is derived from *sterculus*, as that from *stercus*, some of the species being remarkable for the strong and disagreeable odour of their leaves or flowers. The genus is characterised by having polygamous or monœcious flowers. Calyx 5-lobed, somewhat coriaceous. Petals wanting. Stamens monadelphous, disposed in a short sessile or stipitate urceolus. Anthers adnate, ten, fifteen, twenty, in one or two rows; solitary or ternately aggregate. Ovary stipitate or sessile. Carpels follicular, five, or fewer from abortion, distinct, 1-celled, one or many seeded, opening on the inner side; seeds disposed in two rows along the suture of the carpels; sometimes, when the carpels have opened and become spread out, the seeds appear to be arranged along the sides of a leaf-like membrane. Seeds with fleshy albumen, and flat, leafy, equal cotyledons. The species consist of various-sized trees with soft timber, which are found in the tropical parts of the world, with simple or compound leaves and axillary panicles or racemes of flowers. Many of them are of considerable use in the countries where they are indigenous. Like the family to which they belong, several species are mucilaginous; and others yield fibre, which, from its tenacity, is made into ropes. Some yield a gummy exudation resembling tragacanth, and which is sometimes substituted for it: thus the gum called tragacanth, which is sometimes imported from Sierra Leone, is said by Dr. Lindley to be yielded by a species which he calls S. Tragacantha, the S. pubescens of others. So Dr. Roxburgh states *kuteera* gum, which is often substituted for tragacanth, to be produced by S. urens, a tree of the mountains of the Coromandel Coast. Dr. Royle however states that the kuteera gum of many parts of India is yielded by Cochlospermum Gossypium. S. guttata yields a bark, from which the natives of Malabar prepare flax-like fibres, of which the natives of Wynaad make a sort of clothing. S. acuminata is a native of the tropical parts of the western coast of Africa, where its seeds are everywhere known by the name of cola or kola, and are mentioned by most travellers. They are much esteemed by the natives, who take a portion of one of them before each of their meals, as they believe that these seeds increase the flavour of anything they may subsequently eat or drink. They are about the size of a pigeon's egg, are bitter in taste, and may be supposed to have some stomachic properties. The seeds of S. macrocarpa and of S. heterophylla are also called cola on the African coast. In Asia, in the same way, the seeds of S. Balanghas, are described by Rumphius as being roasted and eaten by the natives of Amboyna, while the capsules are burned for the preparation of the colouring-matter called *cassoumba*. The seeds of S. urens and of S. fœtida are likewise eaten in India after having been roasted, as are those of S. Chicha in Brazil. Those of S. alata are also said to be used as a cheap substitute for opium in the district of Silhet; but this statement, implying the presence of narcotic principles, requires careful examination before it can be received as a fact, as we generally find an accordance rather than so great a difference in the properties of species of the same genus.

STERCULIA'CEÆ, a natural order of plants belonging to the syncarpous group of polypetalous Exogens. The plants belonging to this order are trees or shrubs, with alternate, stipulate, simple, often toothed leaves, with a variable inflorescence, and a stellate pubescence. The calyx is either naked or surrounded with an involucre, consisting of 5 sepals, with a valvular or nearly valvular æstivation; 5 petals hypogynous, often saccate at the base; stamens definite or indefinite, and monadelphous; anthers 2-celled; the pistil consists of 5 carpels, often surrounding a columnar gynophore; fruit a capsule with 3 or 5 cells; seeds often winged, sometimes woolly; albumen oily or fleshy, and embryo straight; cotyledons either flat and plaited, or rolled round the plumule.

The order thus defined includes several groups of plants, which have by many writers been made to form distinct orders. Sterculiaceæ are most nearly allied to Malvaceæ, from which they differ in the possession of 2-celled anthers. From Dipteraceæ and Tiliaceæ, to which they are allied by the valvate æstivation of the calyx, they differ in the possession of monadelphous stamens. The subdivisions of this order are marked by very evident peculiarities of structure:—

Helictereæ have an irregular calyx and corolla.

Sterculieæ, no petals, and definite stamens placed at the end of a long column.

Bombaceæ, a calyx with a ruptile dehiscence, usually woolly seeds, and the cells of the anthers anfractuose.

Dombeyæ, a part of the stamens sterile and flat well-formed petals.

Byttnerieæ, a part of the stamens sterile, and small petals bagged at the base.

Lasiopetaleæ, a petaloid calyx and rudimentary petal.

Hermannieæ, spirally twisted petals with only 5 stamens, and those opposite the petals.

Sterculiaceæ are natives of India, New Holland, the Cape of Good Hope, and South America, with the West Indies. Most of its subdivisions have however a very definite geographical range.

Sterculieæ are found in India and equinoctial Africa. The genus Sterculia contains many species that are used as food or medicine. [STERCULIA.]

Byttneriеæ are principally natives of South America and the West Indies; about one-seventh of the species are found in the East Indies, and the same proportion in New Holland. To this group belongs the plant that produces the cocoa [THEOBROMA] of commerce. These plants, like the whole of the order and its allies, abound with mucilage, and are often used in medicine as demulcents. The fruit of *Guazuma ulmifolia* possesses a mucilaginous pulp, and is eaten in Mexico by man, but principally employed for feeding cattle. The bark of this plant is bitter, and is said to be serviceable in the horrible disease called Elephantiasis.

Hermanniеæ—two-thirds are found at the Cape of Good Hope; the remainder are natives of the East and West Indies, South America, and the islands of the Pacific. The species of *Waltheria* abound in mucilage, and are used in medicine as demulcents.

Dombeyæ are all African, East Indian, or South American. Their properties are similar to the preceding. One of the species, *Wallichia spectabilis*, forms a handsome tree, approaching the linden, and points out a relation between this order and Tiliaceæ.

Lasiopetalæ are found entirely in New Holland, and possess no remarkable properties. For further information on the properties of plants of this order see BOMBACEÆ, ADANSONIA, STERCULIA, THEOBROMA.

Sterculia chicha.

a, Branch with leaves and apetalous flowers; *b*, Monadelphous stamens surrounding pistil; *c*, Ovary, style, and stigma; *d*, Section of fruit, showing its 5 cells.

STEREOGRAPHIC. This word, which is derived from *στερεός*, 'solid,' and *γράφειν*, 'to draw,' and which therefore ought to be applied to every method of representing a solid in a plane, has nevertheless a limited technical sense, being applied to that projection of a sphere in which the eye is at a point in the sphere, and the plane of projection is the great circle of which the eye is at the pole, or a plane parallel to it. This mode of projection was known to Hipparchus, and was first described in the work on the planisphere attributed to Ptolemy.

The stereographic projection has two remarkable properties. The first is, that all circles are projected either into straight lines or circles. Those which pass through the eye are of course projected into straight lines; in every other case the projection is the SUBCONTRARY section of a cone, which has its vertex at the eye, and the circle to be projected for its base; consequently the projection is a circle. As much of the circle as lies below the plane of projection (the eye being considered as above it) is projected inside the great circle on which projection is made; and all the rest outside: when this projection is employed in maps, it is usual to place all the part of the globe to be projected below the plane of projection.

The second property is, that the angle made by two circles which meet on the globe, is equal to the angle made, at the point of meeting, by the two circles which are the projections of those circles, the angle made by two intersecting circles on the globe being always that made by their tangents. This property is easily proved as follows: Draw through the point of intersection of the two circles (A and B) which are to be projected, two other circles (A′ and B′), which have the same tangents, and pass through the eye. Then the tangents of A′ and B′ at the eye make the same angle as those at the other point of intersection; that is, as the tangents of A and B at the point to be projected. But these tangents of A′ and B′ at the eye are parallel to the *projections* of the tangents of A and B at the point to be projected: whence the projections of these tangents of A and B make the some angle as the tangents themselves.

The first property was known to Hipparchus and Ptolemy: the history of the second is rather curious. The first writer who seems to have looked attentively for a discoverer was Delambre (*Mém. Inst.*, vol. v., p. 393), who could not find it in Clavius, Stoffler, or any of the writers of the middle ages, who have treated pretty voluminously on the astrolabe, which word, as used by them, merely meant a stereographic projection. That it was mentioned (without demonstration) in the French Mathematical Dictionary of Savérien (1753), in an article which was copied word for word into the 'Encyclopédie,' was all that Delambre could then say of its origin. He afterwards, in writing his *History* of Astronomy in the Middle Ages, found the proposition demonstrated in the 'Compleat System of Astronomy,' by Charles Leadbetter, London, 1728; but, judging from the rest of the work, he presumes that Leadbetter could not have been the discoverer. No claim however has been put in for any one else, and we think it somewhat of an additional presumption in favour of Leadbetter that Savérien's article, which, appearing in the 'Encyclopédie,' first called general attention to the property, can be traced to Leadbetter's work nearly. For we find that Savérien translated his article, word for word, from the second edition (1743) of Stone's 'Mathematical Dictionary.' Stone was a contemporary of Leadbetter, and several times refers to his writings. In any case, however, until another inventor can be shown, the last-named mathematician must not be deprived of his right because he does not appear to have done other things as remarkable as this one.

The consequence of Leadbetter's theorem is, that any small portion of the sphere is projected into a figure very nearly similar to itself, so that any not very large portion of the earth preserves its figure with tolerable accuracy in the map. Hence some writers have said that there is no distortion in the stereographic projection, which is not absolutely true, though nearly so of countries which bear no greater proportion to the whole earth than most of them.

The mode of laying down the stereographic projection, which we cannot here give at length, may be found in the memoir of Delambre above cited, in the work on Practical Geometry published by the Society for the Diffusion of Useful Knowledge, or in any work on the construction of maps.

After correcting the proof of the preceding, we had occasion to consult the third edition of Dr. Harris's 'Lexicon Technicum' (1716); and feeling sure, with regard to that work, that such a proposition as the one called Leadbetter's would be stated, if it were then known, we turned to the article 'Spherick Geometry,' and there we found it, with a demonstration, enunciated as follows:—'All Angles made by Circles on the Superficies of the Sphere are equal to those made by their Representatives on the Plane of the Projection.' The claim of Leadbetter is therefore overthrown. In the preface, Harris says that under (among others) 'Spherical Geometry' will be found entire treatises, which, if he mistakes not, are as short and plain as any extant. If this proposition had been new, he would probably have

noted it here, particularly if it had been his own. We find however, finally, that the property was lately shown (*Encyc. Brit.*, 'Projection') to have been demonstrated by Halley in No. 219 of the 'Philosophical Transactions,' and is attributed by him to De Moivre or Hook.

STEREOTOMY. [PERSPECTIVE.]

STEREOTYPE. The art of stereotype printing is the printing from cast plates of type-metal in lieu of moveable letters or types, and derives its name from the Greek στερεός, firm or fixed, and τύπος, a figure or type. This art is a remarkable illustration of the tendency of some inventions to return, after a long course of improvement, very near to their original simplicity. In the commencement of the art of printing, solid blocks of wood were used, containing, in one piece, all the words of which a page was composed. A great improvement upon this plan was the use of single letters or types, which might be combined into words and pages, and, after being printed from, might be distributed and re-arranged for another work. Then followed the process of type-founding, or casting the letters individually in moulds, by which they might be multiplied with facility, and, being engraved originally upon steel punches, might be executed with greater neatness. Whether the early printers employed logotypes, that is, types for printing whole syllables or words, to any material extent, is not very certain; but it is well known that many persons have proposed, since the introduction of moveable types, the use of such logotypes for the purpose of facilitating the operation of printing; while others have adopted processes which approach more nearly to the old plan of printing from page-blocks, either by fusing the types composing a page into a solid mass, or, as in the modern art of stereotyping, by taking a mould from the page or *form* of moveable types, and using it as the matrix in which to make a solid cast or plate of metal. The face of such a cast is a fac-simile of the types from which the mould is taken, and may be printed from in the same manner as the original form or page.

Many of the accounts of the various projects which bear an affinity to the art of stereotyping, as practised by modern printers, are very indistinct; and the claims of some of the projectors are exceedingly perplexing. Those readers who desire minute information may consult works which enter at length into the history of printing, and especially a very interesting 'Essay on the Origin and Progress of Stereotype Printing,' published in 1820 by Mr. Hodgson, of Newcastle. The subject is also treated at considerable length in Hansard's 'Typographia;' but much of the history contained in that work is derived from the volume before mentioned.

One of the earliest schemes which claims notice in this brief sketch is that which was tried at the beginning of the last century by a Dutchman named Van der Mey. The booksellers Luchtmans, of Leyden, in a letter dated 1801, which was printed by M. Camus, in his 'Histoire et Procédés du Polytypage et de la Stéréotypie,' described some plates or blocks formed by Van der Mey, which had been used in their establishment ever since 1711. These were the forms for a quarto Bible; but a few other works were executed in the same way. They were not cast solid, but consisted of ordinary types, which, after being set up in the usual way, were converted into a solid mass by soldering them together at the back. The great expense of forms prepared in this way, as well as their inconvenient weight and bulk, is quite sufficient to account for the plan having fallen into disuse. It was indeed only applicable in those very rare cases in which it was desirable, in order to meet a constant demand, to keep the forms of type standing; and was preferable to that practice only inasmuch as it avoided the risk of some of the letters being accidentally loosened and misplaced.

William Ged, a goldsmith of Edinburgh, if not absolutely the first, was one of the first to practise stereotyping, according to the common acceptation of the word. His claim to this honour is recorded in a rare pamphlet published by Nichols in 1781, and reprinted in 1819 by Hodgson of Newcastle, entitled 'Biographical Memoirs of William Ged, including a particular account of his progress in the art of Block-printing.' From this work it appears that Ged invented a process for casting whole pages about the year 1725, and that a few years afterwards he and others who were associated with him attempted to apply his invention to the production of bibles and prayer-books for the university of Cambridge. One of the difficulties to be encountered in the introduction of this innovation was the prejudice and opposition of the compositors, who, by the artful production of errors in the forms of type, rendered the casts so incorrect as to bring them into discredit. The scheme was abandoned by the University, and most of the plates were destroyed. A battered and otherwise imperfect specimen which escaped the melting-pot is printed in Hansard's 'Typographia.' Ged cast plates for a few other works; one of which was an edition of Sallust, in 18mo., which, according to his son and daughter, was executed in 1736, though Hodgson says that he never saw a copy dated earlier than 1739, and that the edition commonly bears the date 1744. In Hodgson's Essay a page of this work is reprinted, which is a far better specimen of stereotyping than that given by Hansard. This plate, which had been previously printed in the tenth volume of the 'Philosophical Magazine,' is about a quarter of an inch thick.

About the year 1780, Mr. Tilloch, editor of the 'Philosophical Magazine,' conceived the possibility of founding whole pages; he being, at that time, unacquainted with the prior experiments of Ged. He communicated his idea to Foulis, printer to the university of Glasgow; and they jointly produced several works; some of which were circulated without any intimation of the process by which they were printed. Hodgson gives very good specimens of their work. Finding some inconvenience in the use of blocks of wood for mounting the plates, in order to raise them to the same height as type, these experimentalists tried blocks of brass, having slits through which small screws might pass to secure the stereotype plates; the screws being fastened by nuts on the under side of the brass mounts. In order to bed the plates as evenly as possible, whether the mount were of brass or wood, they interposed a layer of cement between the plate and the mount. In the latter case the thickness and level were adjusted by planing the back or under side of the wood; and in the former by warming the mount, and then placing it, with the plate, into a press, and squeezing out the superfluous cement. An account of the experiments of Tilloch and Foulis was published in the tenth volume of the 'Philosophical Magazine.' Satisfactory as they were, they did not immediately lead to the adoption of stereotype printing.

Towards the latter end of the eighteenth century, many projects were brought forward in France for multiplying engraved blocks or forms of type by processes more or less resembling that of stereotyping, under the names of polytype, stereotype, &c. In some of these the form was imitated by striking upon a mass of soft metal in a state intermediate between perfect fusion and perfect solidity, on the principle of the process now practised in France under the name of *clichage*. The extensive issues of assignats by the revolutionary government gave an impulse to such schemes, of which many were devised, and some were brought into operation, in order to render the assignats more difficult of imitation. In 1798 a stereotype edition of Virgil was published by the Didots and M. Herman; and it appears from Hodgson that, before the close of the century, the wood-engravers of Paris sold metal casts of their wood-cuts.

Some of the early experiments of Senefelder, the inventor of lithography [SENEFELDER, vol. xxi., p. 229] were directed to the discovery of a means of stereotyping by which he might be enabled to print his own works with a very small stock of type. He formed a composition of clay, fine sand, flour, and pulverised charcoal, mixed with a little water, and kneaded as stiff as possible; and with this paste he made a mould from a page of types, which became, in a quarter of an hour, so hard that he could take a very perfect cast from it in melted sealing-wax, by means of a hand-press. He states that, by mixing a little pulverised plaster of Paris with the sealing-wax, the stereotype plates thus produced were much harder than the common type-metal of lead and antimony. The want of pecuniary means for carrying on this project led him to abandon it, and to contrive a plan for printing from stone. Another ingenious proposal which may be here mentioned, is that of Professor Wilson, of Glasgow, who, in 1797, devised a method of multiplying engraved blocks or plates by stereotype or rather polytype impressions in glass or enamel, which, it was anticipated, would prove very durable, and might be applied with advantage to the prevention of forgery. Hodgson gives specimens of two casts of small wood cuts produced in this manner.

The revival and introduction into common use of the ste-

reotyping process is, in a great measure, due to the exertions of Earl Stanhope, about the commencement of the present century. Mr. Tilloch communicated to him the result of his experiments, and Foulis, who, as before stated, had been associated with Tilloch, assisted in the trials made at his lordship's seat at Chevening, in Kent. Andrew Wilson also was connected with these operations, and exerted himself much to introduce the process. The latter individual, who received a gold medal from the Society of Arts in 1810, for his 'great skill and exertions in stereotype printing,' produced several important stereotyped works, of which Hodgson considers his edition of Walker's 'Pronouncing Dictionary,' executed in 1809, to be the best. A specimen of his work, which was printed in the twenty-eighth volume of the 'Transactions' of the Society of Arts (pp. 323-4), shows that he was then able to produce very good casting from type as small as Nonpareil and Pearl. In 1803 or 1804 the process which had been perfected at Chevening was communicated to the university of Cambridge, and shortly afterwards to that of Oxford; but the first work printed in this way at the former place did not appear until 1807, and 1809 is the date of the earliest stereotyped book issued at Oxford.

In setting-up a form intended for stereotyping from, the *spaces*, or short pieces of metal by which the words are separated from each other, and the *quadrats*, or larger spaces by which blank lines are filled up, are cast higher than usual. The types are set up and formed into pages in the usual manner, with the illustrative wood-cuts, if there be any; but, instead of these pages being arranged into a form of sufficient size to print a whole sheet, each page, if large, or every two or four pages, if small, is separately locked up in a small frame or *chase;* the pages being surrounded by fillets of wood or metal, which serve in the cast to form a border for attaching the plate to its mount. The face of the types is then moistened with oil, to prevent the mould from adhering to them. A brass frame, rather larger than the page, is laid upon the chase, in order to retain the plaster while in a fluid state, and to regulate the thickness of the mould. The plaster is then poured on the types, and it soon sets into a solid mass, which must be removed from the types with great care, trimmed on the edges with a knife. The plaster moulds are, in the next place, baked in an oven heated to about 400° Fahrenheit, until they are thoroughly dry and hard. They are placed upright in a rack, and are usually dried in about two hours. Great care is required in this process, especially when the moulds are large, to prevent them from warping.

After being baked, the mould is placed, with its face downwards, upon a smooth plate of iron, called a *floating-plate*, which lies at the bottom of a cast-iron box rather larger than the mould. The box is then covered in by a lid, the under surface of which is made perfectly flat, and which has the corners cut off, to allow the melted metal to enter the box. The cover is firmly held down by a screw, which is attached to an apparatus by which the box is suspended from a crane. It should be observed that the casting-box and plate are heated to the same temperature as the mould, before it is inserted. The box is then swung by the crane over the metal-pit, which is an open iron vessel containing a large quantity of melted metal, resembling in its composition that used for casting types; and it is lowered into the metal in a nearly horizontal position, being a very little inclined, to facilitate the escape of air from the mould and box. The melted metal runs in at the corners of the box; and, by its greater specific gravity, floats up the plate with the mould, forcing the latter tightly against the lid of the box. By this contrivance the metal is forced, by hydrostatic pressure, into every part of the mould; in the margin of which notches are cut to allow free passage for the metal between it and the floating-plate. After remaining immersed in the metal for about ten minutes, the box is gently raised, and removed by the crane to a trough in which its lower part is rapidly cooled by contact with cold water. While the box is cooling, the caster pours in a little metal at the corners, to fill the space left by the contraction of the metal, and so to keep up the necessary pressure upon the cast. When cold, the contents of the box are removed in a mass, from which the superfluous metal is broken off by blows from a mallet. The plaster mould is then broken away from the cast, the face of which is a fac-simile of the types and engravings from which the mould was taken. As the mould is destroyed by this process, it is necessary, when several stereotype plates of the same page are required, to take a distinct plaster mould for each.

The above is the mode of casting usually practised in England; but a different plan has been successfully adopted by Mr. Allen of Edinburgh. The pages of the seventh edition of the 'Encyclopædia Britannica' are stereotyped by the new process alluded to, which is minutely described in the article 'Printing' in that work. The casting-box is, in this case, of sufficient depth to receive several moulds in a vertical position, so that, of the work just alluded to, five pages are cast simultaneously. Another plan which has been tried for the production of stereotype plates too large for casting in the ordinary way, but which we believe has not proved very successful, is to place the mould in a flat iron box, having a trough-shaped mouth at one end, and to pour in the metal with the mould-box, which must be previously heated, in an inclined position. The method of striking the moulds, and from them the plates themselves, by letting the original or pattern types or blocks fall upon a mass of soft metal in a half-melted state, is practised in France, and has been repeatedly tried in this country: it is especially adapted for the production of copies of wood engravings, but it is very liable to injure a delicately engraved block. In this, as in the ordinary casting process, the original engraved blocks should be smeared with some substance that may prevent the cast from adhering to them. In the 'Treatise on Wood Engraving' by Messrs. Chatto and Jackson, a composition of common yellow soap and red ochre is recommended for this purpose.

The alloys used for various kinds of stereotyping differ slightly in their composition, but generally consist of type metal. [TYPE FOUNDING.]

In the year 1820 Mr. (now Sir M. I.) Brunel patented a method of stereotyping intended chiefly for newspaper work, which, though not brought into operation, may afford a useful hint. He proposed to form a mould of a composition of pipe-clay, chalk or burnt clay, finely powdered, and starch, mixed up with water into a stiff paste, and spread upon a thin and flexible plate of steel. The paste was then to be covered with several thicknesses of fine calico, and a skin of wet parchment, and pressed upon the types, to squeeze it into the general form. After this the calico and parchment were to be removed, and two sheets of paper placed in their stead; the mould then received another pressure, by which it was rendered more like the face of the types. Finally, the papers were to be removed, and the impression perfected by pressing the mould immediately upon the surface of the types, which should then be smeared with oil. From this mould a cast was to be taken in metal for printing from. By the proposed application of this process to newspaper printing it was conceived that time might be saved by printing in duplicate, or by bending the plates on to the surface of a cylinder, by which means they might be printed from more rapidly than when flat. By another plan mentioned in the same patent, a kind of stereotype plate was to be formed of shell-lac, spread upon a plate of iron, and coated with a thin film of type-metal. These plans are more fully described in Hansard's 'Typographia.'

Stereotype-plates need careful examination and *picking*, to remove the imperfections in the casting. Small hollows, such as the loops of an a, an e, or an o, are liable to be filled up with metal, owing to blebs of air in the mould, and the fine white lines in wood-engravings are sometimes filled up. Such matters should be corrected by the picker, who should also cut down, with suitable tools, such blank spaces as might be liable to soil in printing. Before printing, also, defective letters or words which cannot be corrected by the picker should be cut away, and types inserted in their place. These types are soldered into holes drilled through the plate; their stems being sawn off flush with the back.

Although the plates are cast of as equal a thickness as possible, they require, before printing from, to be accurately flattened at the back by means of a peculiar kind of lathe, in which a steel cutter, or *knife*, mounted in a slide-rest, shaves off the metal from the back of the plate in concentric circles, until it is made perfectly even. They are then mounted upon blocks of wood or metal, to raise them to the same height as common types. The tendency of wood to warp when exposed to changes of temperature, or to occasional wetting, has led to many projects for mounting stereotype-plates upon blocks of cement, or upon metallic mounts which might be applicable to plates of various sizes. When wooden blocks are used, the plates

are usually secured to them by clips at the edges, and sometimes by screws.

The process of stereotyping is one of the most important means by which the production of cheap books has been facilitated of late years. For a work of limited and temporary demand it is unnecessary; but where the demand is very great, and likely to last for several years, it is all-important, since it enables the publisher to keep up the supply without the expense of having a very large edition printed at once. In most cases where the demand is uncertain, and in almost all where the demand is sure to be large, it is desirable to resort to stereotyping, because, although it increases the first cost of production, it enables the publisher to avoid, on the one hand, the risk of printing a great number of copies which may prove unsaleable, and, on the other, the outlay necessary for the re-composition of the types, in case the demand should exceed the number of copies first printed. For instance, for a work now preparing for publication in demy octavo, the estimate stands as follows:—

Composing, per sheet	.	.	£3 10 0
Corrections, per sheet	.	.	2 0 0
			£5 10 0

The extent of the sale is very uncertain, so that, without the aid of stereotyping, the publisher must either run the risk of printing a long number, or incur the repetition of this expense of 5*l*. 10*s*. per sheet, if the sale should outrun the first edition. In case of reprinting, the same difficulty would occur as to the number which might be required, as the forms of type must be immediately distributed, and therefore the extent of the impression must again be a matter of hazard. All this uncertainty may be avoided by stereotyping the forms, which will occasion an increased outlay, in the first instance, of 2*l*. 2*s*. per sheet. A small number of copies may then be printed, and, if the demand should continue, re-issues of a few hundreds each may be made at the mere cost of paper and press-work, and without the delay and risk of error consequent upon re-composition. The 'Library of Useful Knowledge,' and several other works of the Society for the Diffusion of Useful Knowledge, present striking examples of the advantages alluded to, since, although the demand has been very large and long-continued, and the number of copies sold of some works has greatly exceeded that of others of the same series, the supply has never been interrupted, nor has the expense of re-composition ever been incurred. In cases where great numbers are required at once, stereotyping has been found very useful, since two or more sets of plates may be made, and printed from simultaneously. Its advantages have been particularly felt in the production of the 'Penny Magazine,' and similar works. (See *Penny Magazine*, No. 107, for a fuller enumeration of them.) 'Chambers's Edinburgh Journal' is another remarkable instance of the utility of this process; since it enables the publishers to print their London edition in London, by merely sending eight stereotype plates from Edinburgh every week, instead of having to send many thousand printed copies, at a much greater expense.

It has often been urged as an objection to stereotype printing that it tends to perpetuate errors; but the fallacy of such a statement may be easily shown. In re-composition new typographical errors are pretty sure to arise, while the expurgation of old ones is by no means certain; but in stereotype plates the occurrence of new errors (excepting by the breaking off of a letter or figure) is impossible, and original errors may be altered whenever they are discovered. Such alterations are not necessarily confined to the insertion of a letter or a word; for whole sentences and paragraphs may be altered in like way, provided that the new matter be made the same in extent as that which is cut away. Hence a stereotyped work may be gradually rendered almost immaculate; and an error which would otherwise have run through the whole edition, may be corrected when only a few hundred copies have been circulated.

The multiplication of engravings is an object of little less importance than that for which stereotyping is more extensively used. By the help of this art copies of the wood-cuts in the 'Penny Magazine' and other works are supplied, at a very moderate cost, to publishers in America and on the Continent. This diffusion of engravings has been carried to such an extent, that casts of some illustrations executed for British periodicals have been transmitted to as many as seventeen different countries, for use in similar works.

STERLING, a word applied to all lawful money of Great Britain. In Ruding's work on 'Coinage,' vol. i., p. 13, 4to. edit., the various supposed derivations of the word are given, with a list of the old writers who have adopted each. Ruding himself, after an elaborate examination, says, 'its origin and derivation are still unsettled;' but he inclines, with the majority of the authorities, to attribute it to an abbreviation of Esterlings, people of the north-east of Europe, some of whom were employed in the twelfth century in regulating the coinage of England. The word was not in use before the Conquest, though some have given it a Saxon derivation. In the twelfth century its use was common, and in the following century a writer ascribes its origin to the Esterlings. From the twelfth century English money was designated all over Europe as sterling. By the statute called the Assize of Weights and Measures, which is attributed, in some copies, to the reign of Henry III. (1216-1272), in others to that of Edward I. (1272-1307), 'the king's measure was made so that an English penny, which is called the sterling, shall weigh thirty-two grains of wheat dry in the midst of the ear.' This is the origin of the pennyweight, though it now weighs twenty-four grains.

STERN. [SHIP.]

STERNA. [TERN.]

STERNASPIS. [TESTUDINATA.]

STERNE, LAURENCE, was the great-grandson of Dr. Richard Sterne, who died archbishop of York in 1683. His father, Roger Sterne, second son of Simon Sterne of Elvington and Halifax, having entered the army, became a lieutenant in Handaside's regiment, and on the 25th of September, 1711, o.s., married in Flanders, Agnes, the widow of Captain Hebert, and stepdaughter of a person of the name of Nuttle, whom Sterne himself, in a memoir written for the information of his daughter a short time before his death, describes as 'a noted sutler in Flanders in Queen Anne's wars.' His mother's own family name he professes to have forgotten. Roger's first child, born at Lisle, in July, 1712, was a daughter, Mary, who grew up to be a very beautiful woman, but made an unfortunate marriage, and died early of a broken heart: Laurence was brought into the world, on the 24th of November, 1713, at Clonmel in Ireland, where his father and mother had arrived with the regiment from Dunkirk only a few days before. 'My birthday,' says Sterne, 'was ominous to my poor father, who was, the day after our arrival, with many other brave officers, broke, and sent adrift into the world, with a wife and two children.' The lieutenant upon this betook himself with his wife and family to the family seat at Elvington, near York, where his mother, who had inherited the property from her father, Sir Roger Jaques, resided, her husband having died ten years before; here they all sojourned for about ten months, after which, the regiment being re-established, they set out to join it at Dublin, whence, lieutenant Sterne being within a month ordered to Exeter, his wife and her two infants followed him thither. They remained a twelvemonth in England, and then the lieutenant, with his family increased by another boy, born at Plymouth, was forced once more to turn his face to Ireland. This must have been about the end of the year 1715, if the chronology of the account is to be depended upon. Having got to Dublin, they continued there till the year 1719, which however would be for above three years, instead of only a year and a half, as Sterne seems to state. In that year, he says, 'all unhinged again.' The regiment was ordered to the Isle of Wight, to embark for Spain on the Vigo expedition. On their journey thither from Bristol the younger boy died, but his place was supplied by a girl (who died however in childhood) born in September, 1719, in the Isle of Wight, where the lieutenant left his wife and children till the regiment got back to Wicklow, in Ireland, whither he then sent for them. They lived a year in the barracks at Wicklow, where Mrs. Sterne gave birth to another boy; and then they spent six months with a relation of hers, a Mr. Fetherston, parson of a place called Animo, about seven miles from Wicklow. 'It was in this parish,' says Sterne, 'during our stay, that I had that wonderful escape, in falling through a mill-race whilst the mill was going, and being taken up unhurt; the story is incredible, but known for truth in all that part of Ireland, where hundreds of the common people flocked to see me.' The incident, it seems, is still traditionally remembered in the district,

After this they were in barracks for another year in Dublin—the year 1721—in which, Sterne tells us, he learned to write. The regiment was next ordered to Mullingar, where a collateral descendant of archbishop Sterne found out his relations, or was found out by them, and, taking them all to his 'castle,' entertained them kindly for a year, and then sent them after the regiment to Carrickfergus. On the journey thither, which took six or seven days, and is described as 'most rueful and tedious,' the youngest boy died, and also another infant, a girl, which had been born when they were last in Dublin. In the autumn of this year (1723), or the spring of the next, the subject of the present article, now ten years old, was sent over to England, and put to school, near Halifax, 'with an able master,' says he, 'with whom I stayed same time, till, by God's care of me, my cousin Sterne of Elvington became a father to me, and sent me to the University.' It will be perceived from this detail, that, although Sterne was of English descent and parentage, he was not only by accident a native of Ireland, but spent in that country a considerable part of his early boyhood. No doubt some effect was produced upon his opening powers of thought and observation, by his having been allowed to run wild, as it were, in that land of wit and whim from his seventh to his tenth year.

His father next followed his regiment to Londonderry, 'where,' says the autobiographical sketch, 'another sister was brought forth, Catherine, still living, but most unhappily estranged from me by my uncle's wickedness and her own folly.' From Londonderry the regiment was sent out to defend Gibraltar at the siege (in 1727), where Lieutenant Sterne was run through the body by a brother officer in a duel, and only recovered with much difficulty, and with so shattered a constitution, that when, shortly after, he was sent out to Jamaica, he speedily fell a prey to the country fever, dying at Port Antonio, in March, 1731. 'My father,' says Sterne, 'was a little smart man—active to the last degree in all exercises—most patient of fatigue and disappointments, of which it pleased God to give him full measure; he was in his temper somewhat rapid and hasty, but of a kindly, sweet disposition, void of all design, and so innocent in his own intentions, that he suspected no one; so that you might have cheated him ten times in a day, if nine had not been sufficient for your purpose.'

Meanwhile Sterne remained with his master at Halifax, to whom, from an anecdote which he relates, his dawning genius seems to have been already clearly discernible, till he was sent by his kinsman to the University of Cambridge in 1733. He was admitted of Jesus College on the 6th of July in that year; and he took the degree of B.A. in January, 1736; and that of M.A. at the commencement in 1740. On leaving the university, in what year has not been stated, he took orders, and his uncle, the Rev. Jaques Sterne, LL.D, a younger brother of his father's, and a well-beneficed clergyman, being a prebendary of Durham and of York, and rector of Rise and of Hornsea cum Riston, procured him the living of Sutton, in Yorkshire. It was in the city of York that he met with the lady whom he married in 1741, after having courted her, as he tells us, for two years. Her name is not known; all that appears is that her Christian name began with L., being probably Lydia, like that of her daughter. She brought him some fortune, but probably of no great amount. Sterne's uncle now procured him a prebend in York cathedral; 'but he quarrelled with me afterwards,' says Sterne,' 'because I would not write paragraphs in the newspapers: though he was a party man, I was not, and detested such dirty work, thinking it beneath me: from that period he became my bitterest enemy.' Notwithstanding all this virtuous indignation however, Sterne appears to have gone on doing this 'dirty work' for his uncle for a very considerable length of time—not much less than twenty years. In a letter to a Mrs. F——, written in November, 1759, on the eve of the publication of the first two volumes of his 'Tristram Shandy,' he says, in reply to an inquiry his correspondent had made as to the reason of his turning author, 'Why, truly, I am tired of employing my brains for other people's advantage. 'Tis a foolish sacrifice I have made for some years to an ungrateful person.' It has been asserted that he wrote, or conducted for some time, a periodical electioneering paper published at York in the Whig interest. Soon after his marriage, a friend of his wife's presented him with the living of Stillington, also in Yorkshire; and he tells us he remained near twenty years at Sutton doing duty at both places, which seem to have been within a mile and a half of each other: 'I had then,' he says, 'very good health: books, painting, fiddling, and shooting were my amusements.' During all this space, his only publications, or all at least to which he put his name, were two sermons: the first, entitled 'The Case of Elijah and the Widow of Zarephath considered,' in 1747; the second, entitled 'The Abuses of Conscience,' in 1750. This latter is the same which he afterwards introduced in the second volume of his 'Tristram Shandy' as a Sermon of Yorick's: in the preface to the two first volumes of his collected sermons, which appeared the following year, he says: 'I suppose it is needless to inform the public that the reason of printing these sermons arises altogether from the favourable reception which the sermon given as a sample of them in "Tristram Shandy" met with from the world:—that sermon was printed by itself some years ago, but could find neither purchasers nor readers.' Both sermons were republished in the collection.

The first two volumes of 'Tristram Shandy' were originally published at York, towards the end of the year 1759, and were reprinted at London early in 1760. Although anonymous, the work seems to have been known to be Sterne's from the first; and it raised him at once from obscurity to universal notoriety and high literary fame. This and his subsequent publications—two volumes of Sermons in 1760, vols. 3 and 4 of 'Tristram Shandy' in 1761, vols. 5 and 6 in 1762, vols. 7 and 8 in 1765, two more vols. of Sermons in 1766, the 9th vol. of 'Tristram Shandy' in 1767, and the 'Sentimental Journey' in 1768—probably also brought him a good deal of money; and his circumstances were further improved by his being presented by Lord Falconbridge, in 1760, with the curacy of Coxwold (also, we suppose, in Yorkshire), which he calls 'a sweet retirement, in comparison of Sutton.' His celebrity also, it is to be feared, introduced the Yorkshire parson to new habits of life, and to some kinds of dissipation not quite so innocent as 'fiddling and shooting.' In 1760 he took a house at York for his wife and his only child, a daughter: but his own time he seems from this date to have spent mostly either in London or on the Continent. In 1762, before the conclusion of the peace, he went to France, whither he was soon after followed by his wife and daughter. Leaving them both in that country, he seems to have in the first instance returned to England, whence, in 1764, he proceeded to Italy, with a view to the recovery of his health, now greatly impaired. He returned to England in the earlier part of 1767, and, having after some time persuaded his wife to come over to him with their daughter, he remained at York till he had written all that we have of his 'Sentimental Journey,' the first part, which he then brought up with him to the metropolis, and published, as has been already stated, in the beginning of the following year. He lived merely to see the work brought out; having died, at his lodgings in Bond-street, on the 18th of March, 1768 (not the 13th of September, as is stated on his monument erected some years after in the burying-ground of St. George's, Hanover-square, where he was interred). He had saved nothing, if he did not die in debt; but it is said that, soon after, his wife and daughter being at York during the races, a collection which amounted to a thousand pounds was made for them by some gentlemen there; and they also received a liberal subscription for three more volumes of his Sermons, which were afterwards published. In 1775, after her mother's death, Sterne's daughter, who calls herself, at the end of the dedication to Garrick, Lydia Sterne de Medalle (having been married to a person of the latter name), published three small volumes of his Letters to his Friends, along with the short autobiographical memoir from which many of the above facts have been taken. Some of the letters in this collection are of a very extraordinary character to have been either published by a daughter, or left for publication, as we are assured they were, by a wife. The same year there appeared, under the title of 'Letters to Eliza,' ten letters addressed by Sterne, in March and April, 1767, to an East Indian lady, who is described by the editor as a 'Mrs. Elizabeth Draper, wife of Daniel Draper, Esq., counsellor at Bombay, and at present chief of the factory at Surat.' Having come to England for the recovery of her health, she and Sterne became acquainted and were greatly taken with each other. Sterne's letters however certainly do not warrant us in concluding that they were attached by any other feelings than those of a very warm friendship. The lady had been dead some years, as well as Sterne himself,

when his letters to her were published; and the latter part of her life, the editor tells us, had been attended with circumstances which were 'generally said to have reflected no credit either on her prudence or discretion.' But whether there is any real ground for this slander we greatly doubt. Mrs. Draper returned to her husband in India after her correspondence with Sterne, and, then making a second visit to England, died at Bristol, and was interred in the cathedral, where there is a marble monument erected to her memory. With the exception of one or two fragments, the only other remains of Sterne that have been printed consist of a second collection of letters, in one volume, which also appeared in 1775; with the addition of a piece of humourous satire entitled 'The History of a Watchcoat,' which however had been published separately about seven years before.

In 1793 Dr. Ferriar, of Manchester, published an Essay in the third volume of the 'Memoirs of the Manchester Literary and Philosophical Society,' afterwards enlarged and published separately in 1798, and again in 1802, under the title of 'Illustrations of Sterne,' with the view of showing that many passages in his writings were suggested by or imitated from various old and commonly neglected authors, especially Rabelais and Burton's 'Anatomy of Melancholy.' In a literal sense, the charge is sufficiently established; there are some passages in Sterne which may be fairly said to be copied from Burton, Rabelais, and others; and the germs of a good many of his thoughts and expressions may be found in their pages. Of course also the general spirit of his wit and turn of writing must have taken something from the sources with which he is thus proved to have been familiar. But however these detections may affect Sterne's reputation for honesty, the question of the originality of his genius is not touched by them. A writer of original genius, under the pressure of haste or indolence, may, if not a scrupulous man, borrow or steal occasionally, as well as the most common-place writer. Sterne, we know, was the reverse of scrupulous; but he may also have had no very felonious intention in the appropriations that are laid to his charge; it will be admitted that he has for the most part really put a new life into what he has thus resuscitated; and he probably thought that in all such cases he gave more than he took. The nature of his writings, it is to be remembered, precluded him from making any formal acknowledgement of his obligations; he could not finish off a chapter in 'Tristram Shandy' with a list of references such as might be appended to an article in a dictionary. Beyond all controversy, he is, in his conceptions and delineations separately considered, as well as in his general spirit and manner, one of the most original of writers. His humour is quite as much *sui generis* as that of either Rabelais or Cervantes or Swift. Whatever he may have in common with any or all of these, he has much more in which he differs from them, and that is wholly his own. He is, of all English humourists at least, the airiest and most buoyant. And it is wonderful what a truth and real humanity there is even in his most startling and eccentric creations; how perfectly unity of character and every artistic probability is preserved in each of them; how they all draw our sympathies towards them; how they live like actual existences in our memories and our hearts. It is rather a simple fact than an opinion that the first class of Sterne's *dramatis personæ*, his Uncle Tobys, his Corporal Trims, his Yoricks, rank in that department of our literature next to the Launces and Touchstones, the Malvolios and Justice Shallows, of Shakspere, and far apart from all else of the same kind in the language. In the mere art of writing also, his execution, amid much apparent extravagance, is singularly careful and perfect; it will be found that every touch has been well considered, has its proper purpose and meaning, and performs its part in producing the effect; but the art of arts, the *ars celare artem*, never was possessed in a higher degree by any writer than by Sterne. His greatest work, out of all comparison, is undoubtedly his 'Tristram Shandy;' although, among foreigners, the 'Sentimental Journey' seems to stand in the highest estimation. But that will hardly be the judgment of any Englishman,—though it may be of some English women.

STERNHOLD, THOMAS, was a native of Hampshire. The date of his birth is not known. He was educated at Oxford. He was groom of the robes to Henry VIII., and retained the same office under Edward VI., in whose reign he died, August, 1549.

Sternhold's only claim to distinction is, that he was the principal author of the first English metrical version of the Psalms attached to the Book of Common Prayer. He had undertaken to versify the whole of the Psalms, but completed only fifty-one: the rest were translated by John Hopkins and others. Sternhold's version was not published till after his death: 'All such Psalms of David as Thomas Sternholde did in his Lyfe drawe into English Metre,' London, 1549, 8vo. He was also the author of 'Certain Chapters of the Proverbs of Solomon, drawen into Metre,' London, 1549, 8vo. The complete version of the Psalms by Sternhold and Hopkins was not published till 1562, when it was first annexed to the Book of Common Prayer, with the title of 'The whole Booke of Psalmes, collected into English Metre, by T. Sternhold, J. Hopkins, and others, conferred with the Ebrue, with apt Notes to sing withal.' The printing was in black letter, and the music consisted of the melodies only, without base or other part. Many of the best melodies were adaptations from the German and French. [PSALMODY.]

The Reformation introduced metrical versions of the Psalms. The Earl of Surrey, who was beheaded Jan. 19, 1546-7, translated some of the Psalms and Ecclesiastes into verse, which, together with a few poems, were printed by Dr. Percy, but never published, the whole impression having been consumed in the fire which destroyed the printing-office of Mr. Nichols in 1808. Sir Thomas Wyatt also published 'Certayne Psalmes, chosen out of the Psalmes of Dauid, commonly called vij. Penytentiall Psalmes, drawn into Englishe Metre; whereunto is added a Prolog of the Aucthore before euery Psalme, very pleasaunt and profettable to the godly Reader,' London, 1549, 8vo. In the same year was published 'The Psalter of Dauid, newly translated in Englyshe Metre, in such sort that it may more decently and with more delight of the mynd be reade and songe of al men; whereunto is added a Note of four parts, wyth other thynges,' &c., London, 1549.

Campbell, in his 'Specimens of English Poetry' (vol. *i.*, 'Essay on English Poetry') observes, that 'in the reign of Edward VI. the effects of the Reformation became visible in our poetry, by blending religious with poetical enthusiasm, or rather by substituting the one for the other. The national muse became puritanical, and was not improved by the change. Then flourished Sternhold and Hopkins, who, with the best intentions and the worst taste, degraded the spirit of Hebrew Psalmody by flat and homely phraseology; and mistaking vulgarity for simplicity, turned into bathos what they found sublime. Such was the love of versifying holy writ at that period, that the Acts of the Apostles were rhymed and set to music by Christopher Tye.' Tye's book is entitled 'The Actes of the Apostles; translated into Englyshe Metre, and dedicated to the Kynge's moste excellent Majestye, by Cristofer Tye, Doctor in Musyke and one of the Gentylmen of his Grace's most honorable Chappell; wyth Notes to eche Chapter, to synge and also to playe upon the Lute, very necessarye for Studentes after theyr studye to fyle theyr wyttes, and also for all Christians that cannot synge to read the good and godlie storyes of the Liues of Christ hys Apostles,' Lond., 1553, sm. 8vo.

(Watt's *Bibliotheca Britannica*, &c.)

STERNOTHE'RUS. [TESTUDINATA.]

STERNUM. [SKELETON.]

STERNUTORIES, called also Ptarmics, agents which cause sneezing. The most familiar are snuffs of different kinds, many of which cause likewise a flow of the natural secretion from the nose, when they are termed errhines. [ERRHINES.] Sternutories are chiefly employed to occasion a violent succession of the frame, either to restore suspended respiration, as in some cases of fainting, or to dislodge some foreign body from the nasal passages or windpipe, or more rarely to cause the bursting of abscesses in the tonsils. They are also used to avert impending fits of hysteria or epilepsy, or to terminate prolonged hiccup. Their use requires caution in individuals disposed to apoplexy or affected with rupture. They are generally improper for pregnant women and young children. They occasionally excite too violent and continued sneezing, which may be controlled by creasote, breathing diluted carbonic acid, or putting a sinapism round the throat.

STESI'CHORUS, one of the earliest and most celebrated lyric poets of antient Greece. The few and fragmentary accounts which we have of him, are not only in direct contradiction to one another, but are manifestly interwoven with various mythical elements. All accounts however agree that he was a native of Himera in Sicily, and son of Euphe-

mus. (Plat., *Phaedr.*, p. 244; Steph. Byz., *s. v.* Ματαυρός.) Among the various statements of the date of his birth, the most probable is, that it was about B.C. 643. He lived to the age of 83, his death having probably taken place in 560 B.C. In his later years therefore he witnessed the tyranny of Phalaris, against whom he is said to have cautioned his fellow-citizens in an apologue called the 'Horse and the Stag.' (Aristot., *Rhet.*, ii. 20; Conon, *Narrat.*, 42; comp. Horat., *Epist.*, i. 10, 34, &c.) The population of Himera consisted of Zanclæans and Syracusans, but the family of Stesichorus had come to the colony from Metaurus. He is said to have been blind for some time, and according to the story this punishment was inflicted on him for having offended by his poems the shade of Helen. His original name was, according to Suidas (*s. v.* Στησίχορος), Tisias, and he assumed the name of Stesichorus as indicating the art to which he mainly devoted his life, that is, the art of training and directing the solemn choruses at the religious festivals. This art appears to have been hereditary in his family, which may be inferred from the fact, that, according to some writers, he was descended from Hesiod, and that after his death there occur two Himeraeans of the same name, who were likewise distinguished in this art. (Marm. Par., *Ep.* 50 and 73.) But Stesichorus Tisias was the most celebrated of the family. It was he who gave to the choral songs the artistic form which was subsequently brought to perfection by Pindar. Before his time a chorus simply consisted of strophes and antistrophes. Stesichorus added the epode, during the recitation of which the choruses stood still. The movements and arrangement of the chorus-dancers were likewise settled by him in a manner which was afterwards observed by other teachers of the chorus and poets, and lastly he introduced a greater variety of characteristic metres than had been hitherto used in the composition of choruses, and had them accompanied by the cithara. In short Stesichorus was regarded by the antients as the creator of the perfect form of this species of poetry, although his choruses were much more simple than those of later times, and bore greater resemblance to epic poetry. The dialect which he used was that of the Epos, interspersed with Dorisms. The subjects of his poetry were all taken from the mythical and heroic ages of Greece, as Quinctilian (x. i. 62) states, and as is clear from the titles and fragments still extant. Some of these epico-lyrical choruses were very long: thus the 'Oresteia' is said to have consisted of two books, and the series of scenes representing the taking of Troy, on the so-called Iliac Table, was taken from this poem. The greater part of these choruses must have consisted of epic narrative; but owing to the solemn character of choral poetry in general, the tone of the narrative is more exalted than in an ordinary epic poem. Quinctilian says that he represented his heroes with their appropriate dignity, and that he might have rivalled Homer himself if he had kept within bounds, and not indulged in an exuberance of words, and not given the reins too much to his imagination. This censure is perfectly justified by the extant fragments.

Besides his choruses Stesichorus composed paeans and hymns which were of a more purely lyrical character. He is also the first Greek poet who wrote erotic poems containing celebrated love stories. The bucolic poetry of Sicily was likewise indebted to him, as he raised it from a rude and unpolished state to classical perfection.

Stesichorus, whom the antients always mention with high admiration, is as a lyric poet totally different from what we usually understand by this term, for his works did not contain any effusions of his own feelings and thoughts, nor did they even, as it would appear, bear any relation to the time and circumstances in which he lived; the subjects were stories belonging to past ages, and taken either from the early traditions of Greece, or from the legends current among the Sicilian peasantry.

After his death the Himeraeans erected a statue, which represented him as a man weighed down by old age, with a book in his hand. (Cic., *c. Verr.*, ii. 35.) Catana disputed with Himera the honour of possessing the tomb of Stesichorus, and magnificent monuments in honour of him were erected in both places.

The fragments of Stesichorus have been collected by J. A. Suchfort, Göttingen, 1771, 4to., and by Blomfield, in the 'Mus. Crit.,' No. 6. The best collection however is that by Kleine, which was published at Berlin, 1828, 8vo., under the title, 'Stesichori Himerensis Fragmenta collegit, Dissertationem de Vitâ et Poesi Auctoris praemisit, C. Fr. Kleine.' They are also contained in Gaisford's 'Poet. Graec. Minor.'

(Müller, *Hist. of the Lit. of Ant. Gr.*, i., p. 197-203; Bode, *Gesch. der Lyrischen Dichtkunst der Hellenen*, ii., p. 40-85.)

STETHOSCOPE. [AUSCULTATION; LAENNEC.]

STETTIN, one of the three governments of the Prussian province of Pomerania, is situated between 52° and 54° 10′ N. lat. and between 13° and 16° E. long. It is bounded on the north by the government of Stralsund and the Baltic; on the east by Koeslin; on the south by Brandenburg; and on the west by Mecklenburg. The area is about 6000 square miles. The population in 1837 was 464,440. The great majority of the inhabitants are Protestants, there being only about 3000 Roman Catholics and 1500 Jews. The government is divided into 21 circles. [POMERANIA.]

STETTIN, the capital of the whole province of Pomerania, as well as of the government of the same name and of the circle of Randow, is one of the most flourishing commercial towns and one of the strongest fortresses in the Prussian monarchy. It is situated in 53° 26′ N. lat. and 14° 45′ E. long., on an eminence on the left bank of the Oder, which divides into four branches, viz. the Oder, or the main stream, the Parnitz, and the Great and the Little Regelitz. The principal and most strongly fortified part of the town is on the left bank of the Oder, and is connected by two wooden bridges, each about 400 feet in length, with the suburb of Lastadie, which extends along the right bank, and is likewise fortified, being protected by ramparts, by the Parnitz, and some marshes. There is another wooden bridge, 380 feet in length, across the Parnitz, one of 120 feet on the Little Regelitz, and one of 630 feet in length on the Great Regelitz. The suburbs Ober- and Unter-Wieck, and of Alt and Neu Torney, are not included in the fortifications. The two latter consist chiefly of farm-houses, inns, and other establishments. The proper citadel is called Fort Prussia, besides which there are forts William and Leopold. The town has five principal gates and eight posterns. There are several squares. Being the capital of Pomerania, as well as of the government of Stettin, it contains all the principal government-offices. Of the public buildings, the most remarkable are—the palace, formerly the residence of the last dukes of Pomerania, the government-house, the arsenal, the house of the provincial estates, with a considerable library, the great barracks, the three hospitals, and the theatre. There are five churches and a Roman Catholic chapel. The above-mentioned library is one of the most complete in Pomerania, and contains many valuable MSS. relative to the history and constitution of the duchy. Besides the gymnasium, to which an observatory is attached, there are a school for training teachers, a school of industry for boys, and a school of navigation, and many others. The charitable institutions are very numerous and well supported. Stettin is the residence of a Protestant bishop and of the French Protestant consistory. The population is 34,000, including the garrison, which is very numerous. The manufactures are woollens, linen, cotton, leather, hats, stockings, ribands, sail-cloth, soap, and tobacco. Boats and ships are built here, and the ships' anchors for all the ships of the Prussian states are manufactured here. The trade of Stettin is very considerable, it being the chief port for the manufactures and produce of Silesia, and for the importation of all kinds of foreign goods, especially colonial produce, for the supply of Silesia, Berlin, and other places. A railway is at present constructing between Stettin and Berlin. The Sound duty makes the conveyance of goods more expensive, and the ships have not always return cargoes. Thus many goods which would naturally be exported from Stettin are sent to Hamburg, which is not subject to the same disadvantage. Another disadvantage is the difficult navigation of the Oder, ships drawing more than seven feet water being obliged to stop at Swinemunde on the Same, one of the channels by which the Oder empties itself into the Baltic. The channel was however deepened in 1827. The number of ships that arrive here annually is about 1000, of which perhaps a fourth may belong to the merchants of Stettin. There are resident consuls of England, France, Russia, Sweden, the Netherlands, Denmark, Hanover, Portugal, and North America.

Among the remarkable persons born at Stettin, was the most extraordinary woman of her age, Sophia Augusta Frederica, princess of Anhalt-Zerbst, afterwards the empress Catherine II. of Russia, and Sophia Dorothea, princess of Würtemberg, mother of the reigning em-

peror of Russia. The fathers of the two empresses were governors of Stettin. The magistrates having complimented Catherine on her accession to the throne, she ordered that one copy of every gold medal struck in Russia should be given to the city, which has between 90 and 100 of these medals. (Müller, *Handbuch;* Hörschelman; Hassel; Stein.)

STEUART, SIR JAMES, born at Edinburgh, October 21, 1712, was the only son of Sir James Steuart, solicitor-general for Scotland, under Queen Anne and George I. After being admitted at the Scotch bar at the age of 24, he proceeded to the Continent, where he spent several years, and at Rome was introduced to the young Pretender. He was unfortunately called to Edinburgh by the illness of his wife at the period of the rebellion of 1745, where his intercourse with Charles Edward was resumed, though he took no part in promoting his designs. After the battle of Culloden he found it prudent to retire to the Continent, where he remained for the next seventeen years. In 1763 he was permitted to return to his native country on the understanding that he would not be molested so long as he remained quiet, but it was not until 1771 that he received a free pardon. Having settled at Coltness, the seat of his family, in the county of Lanark, he finished the most important of his works, on which he had been engaged during his long exile. It was purchased by Andrew Miller, the bookseller, for 500*l*., and appeared in London in 1767, in two quarto volumes, entitled 'An Inquiry into the Principles of Political Economy.' As the British law of copyright did not extend to Ireland, an edition in three volumes octavo was published in Dublin in 1770, which is said to have been circulated rather extensively in the British colonies; and in 1770 a second edition of the work was called for in England. He wrote also on the coinage of Bengal; on a plan of uniform weights and measures; and while on the Continent published in French a 'Vindication of Sir Isaac Newton's Chronology;' and he was also the author of several metaphysical disquisitions, the two principal ones being on Beattie's 'Essay on Truth,' and Mirabaud's 'System of Nature.' He died in November, 1780, aged 67. His only son, General Sir James Steuart, erected a monument to his memory in Westminster Abbey, and in 1805 he published a complete edition of his father's works, in six volumes octavo.

It is remarkable that Adam Smith, whose work on the same subject appeared nine years after Steuart's, has not once referred to his predecessor. He is stated to have said that he understood Sir James's system better from his conversation than his volumes (*Life of Sir J. Steuart*); and Mr. M'Culloch remarks, that his statements and reasonings are 'singularly perplexing, tedious, and inconclusive,' though he adds that his work 'is by no means destitute of enlarged and ingenious views.' The first book treats of population and agriculture; the second, of trade and industry; the third, of money and coin; the fourth, of credit and debts, and incidentally of interest and banks; and the fifth book relates to taxes. At the end of each book there is a useful resumé of the argument. The first book has the merit of placing the theory of population in nearly the same light as that in which it is now generally viewed. The author's want of confidence in the efficacy of the commercial principle is in striking contrast with the views of Adam Smith. He proposed that granaries should be established for the purpose of collecting stores of corn in cheap years and selling them in dear years. But the work is now entirely superseded, and is interesting chiefly in connection with the history of political economy.

STEVENAGE. [HERTFORDSHIRE.]

STEVENS, GEORGE ALEXANDER, was born in London, and brought up to a trade, which he deserted at an early age for the profession of a strolling player, in which he continued several years, chiefly in the Lincoln company. In 1751 he had an attack of illness, and published a poem entitled 'Religion, or the Libertine Repentant.' In 1752 the Libertine had ceased to be repentant, and obtained an engagement at one of the Dublin theatres, where he produced a burlesque tragedy, called 'Distress upon Distress.' In 1753 he was engaged for Covent Garden Theatre, and came to London. Stevens was not a good actor, but he wrote songs which he sang at convivial societies, where he and his songs were much admired. He led a life of dissipation, was generally necessitous, and always extravagant. In 1760 he published a novel, 'The History of Tom Fool,' 2 vols. 12mo.

The first sketch of the work by which Stevens is chiefly known, the 'Lecture on Heads,' was intended for Shuter the actor, to be used at his benefit; but he did not avail himself of it. Stevens then enlarged the plan and improved the details, and having furnished himself with the necessary apparatus of heads, &c., in 1763, or thereabouts, he began to perform it in the principal towns of England and Scotland, with great success and a large profit. He afterwards went to North America, where he was not less successful than he had been in England. After a stay of about two years he returned, and then proceeded to Ireland. In a few years he realised about 10,000*l*. In 1766 he produced a 'Supplement; being a New Lecture upon Heads.' It was only performed six nights. In 1770 he brought out a burletta, 'The Court of Alexander,' which was set to music by Dr. Fisher, but added nothing to the fame of either author or composer. In 1772 he published his 'Songs, Comic and Satirical,' Oxford, 12mo. In 1773 he exhibited 'A Trip to Portsmouth.' After giving his 'Lecture' a few times more, he sold it to Lee Lewis, who, with the assistance of Mr. Pilon, made some improvements, and continued to perform it with tolerable success for some years. Meanwhile Stevens's faculties began to fail, and he sank into a state of fatuity, in which he continued several years, till his death, which took place September 6, 1784, at Biggleswade, in Bedfordshire. (The 'Biographie Universelle' says at Baldock in Hertfordshire, we believe erroneously.) After Stevens's death was published, in 1788, 'The Adventures of a Speculist; compiled from the Papers of G. A. Stevens: with his Life, a Preface, and Notes, by the Editor.'

Stevens's 'Lecture on Heads' has a thin sprinkling of wit, many bad puns, much caricature, and a good deal of satire more extravagant than forcible; but the absurdities of dress, manners, modes of speaking, and other peculiarities of the day, were exhibited with so much liveliness, if not truth, as to render the performance exceedingly attractive. One of the best bits is perhaps the report of the trial, 'Bullum *versus* Boatum.' 'Daniel *versus* Dishclout' is not so good. Stevens's 'Songs, Comic and Satirical,' amount to more than a hundred. They were considered classical by the Choice Spirits of that time, being filled with heathen deities, Venus, Cupid, Mars, Bacchus, and so forth, together with personifications of the virtues and vices. They are chiefly bacchanalian and amatory, several are satirical, a few licentious, but not one 'comic.' Only one has retained its popularity, 'The Storm,' which is indeed the only one which deserves to be popular. It appears in Stevens's Songs as 'The Marine Medley.' It has been since altered; some of the worst lines have been omitted, and others more suitable substituted, the versification of the stanzas made uniform, and indeed the song as a whole is improved. Still there are bad lines, as, for instance, the first, 'Cease, rude Boreas, blustering railer,' but this line is not in the original song. With all its defects however there is so much animation and truth of description, and the scene with all its circumstances is exhibited by the supposed narrator with such natural earnestness and energy, as to render the song, in its kind, perhaps one of the best in the language.

(*Life*, attached to Stevens's *Works;* Baker's *Biographia Dramatica;* Watt's *Bibliotheca Britannica; Biographie Universelle.*)

STEVENS, RICHARD JAMES SAMUEL, a composer of numerous glees, many of which display the most brilliant traits of genius, was born in London, about the year 1753, and educated in St. Paul's cathedral, under Richard Savage, almoner and master of the choristers. His first appointment was as organist to the Temple church. In 1795 he succeeded Mr. Jones in the office of organist of the Charter-house; and in 1801, on the death of Dr. Aylward, was elected professor of music to Gresham college. In 1782 he gained the prize-medal from the Catch Club for a serious glee, and another in 1786 for a cheerful glee. These, with many more compositions of the same class, particularly his five-voiced glee, from Ossian, 'Some of my heroes are low,' in which the poetry and science of music are equally blended, speedily and most deservedly obtained the stamp of public approbation, which they will never lose so long as vocal harmony shall be admired.

Mr. Stevens published three sets of glees and some songs, and edited a useful collection of anthems, &c, in three folio volumes. He died in 1837, leaving one son.

STEVIN, SIMON, a celebrated Flemish mathematician, was born about the middle of the sixteenth century, at Bruges: it has been ascertained that he went to reside in Holland, where he obtained the title of mathematician to Prince Maurice of Nassau, and that he was made civil-engineer to the States, the charge of constructing and repairing the dykes being confided to him. It is to be regretted that no other particulars concerning his life have been preserved: even the year of his death is unknown.

He wrote a treatise on arithmetic, which was printed at Antwerp in 1585; and in the same year he published a collection of geometrical problems in five books. He appears to have studied algebra with great attention, and to have made in that branch of science several improvements. The principal of these consist in the employment of fractional indices, as exponents of the roots of quantities (the use of integers as the exponent of powers had previously been introduced by Stifel), and in a general but laborious method of approximating in numbers to the root of any equation. He represented the unknown quantity by a small circle; and a number, either integral or fractional, contained within the circle, indicated a power or root of that quantity.

In 1586 Stevin published in quarto, and in the Dutch language, his tract on statics and hydrostatics, in the preface of which he endeavours to prove that the Dutch language is more antient than any other; and in the same year he published, also in Dutch, his 'New System of Fortification.' In 1589 he brought out a tract entitled 'De Motu Cœli;' and ten years afterwards, in Dutch, a treatise on navigation: the latter was translated into Latin by Grotius, and published at Leyden in 1624.

In 1605 W. Snell translated into Latin, and published in two volumes, folio, the greater part of the works of Stevin, but he did not live to complete the undertaking. In 1634 however Albert Girard published, at Leyden, the whole of the works in French: this edition contains the treatise on arithmetic; the six books of the algebra of Diophantus (the four first books were translated from the Greek by Stevin, and the others by Girard), and an explanation of the tenth book of Euclid; tracts on cosmography, geography, and astronomy, the practice of geometry, statics, optics, castiametation, a new system of fortification, and a method of fortifying places in which manœuvres of water, by means of sluices, were to contribute to the defence.

The work on statics contains a simplification of the demonstration of Archimedes relating to the fundamental property of the lever. Stevin represented the two weights at the extremities of the lever by parallelopipeds suspended horizontally by strings applied at their middle points: the breadths and depths of these parallelopipeds were equal, but the length of each was double the distance from the fulcrum of the lever to the point from which the other was suspended. When the parallelopipeds were placed end to end, the middle of the whole was vertically under the fulcrum of the lever, and therefore the latter was necessarily in equilibrio, while the weights of the separate parallelopipeds were inversely proportional to the lengths of the arms from whose extremities they were suspended.

In order to exhibit the conditions under which a body is in equilibrio on an inclined plane, Stevinus supposes a triangular prism to be placed with one side parallel to the horizon, so that the other sides may form a double inclined plane; and he imagines a string, on which are placed a number of equal weights, at equal distances from one another, to be laid on those sides across the upper edge of the prism: each part of the string of weights extends from the edge to the base of the prism; or the two extremities of the string are at equal distances below that base. He concludes that the string so placed would be at rest on the two planes, because if it were to begin to move (the string of weights being of infinite length), it would move for ever, which he supposed to be absurd, so that the tendency of the weights to descend on one side must exactly counterbalance the like tendency of those on the other side; and evidently the sum of the weights lying on one plane is to the sum of the weights lying on the other, in the same proportion as the lengths of those planes respectively, the lengths being measured in directions perpendicular to the edge of the prism. Hence he infers that the same power is required to support different bodies on single inclined planes of equal heights, when the weights of the bodies are proportional to the lengths of the planes. If one side of the prism is in a vertical position, the tendency to descend is evidently equal to the weight; and hence, on every inclined plane, the sustaining power, in a direction parallel to the plane, is to the weight of a body, as the height of the plane is to its length.

From this theory, also, Stevin discovered that an equilibrium between three forces acting at one point in a body, takes place when the forces are parallel and proportional to the three sides of a triangle. His demonstration however extends only to the case in which the directions of two of the forces are at right angles to one another; for he states that when a body is supported on an inclined plane, and retained by a force acting parallel to the plane, it is in the same circumstances as if it were suspended by two strings, one perpendicular, and the other parallel to the plane; and he concludes that the ratio of the weight of the body, to a force parallel to the plane, is as the hypotenuse to the base of a right-angled triangle formed by three lines, one in a vertical direction, another perpendicular to the plane, and the base or third side being in a horizontal position.

Stevin is said to have contrived a car which moved by means of sails, on the flats of Holland, with more rapidity than any carriage drawn by horses.

STEWARD, LORD HIGH, OF ENGLAND, one of the antient great officers of state. Under the Norman kings and the early kings of the Plantagenet line it seems to have been an hereditary office. Hugh Grentmesnell held the office in the reign of Henry II., and it passed with his daughter and co-heir in marriage to Robert de Bellomont, who was earl of Leicester. Robert's son held it, on whose death without issue it passed to the husband of his sister, the elder Simon de Montfort, who had also the dignity of earl of Leicester. From him it passed to his son, the second Simon de Montfort, who was slain at the battle of Evesham in 1265. This high dignity then reverted to the crown, but was immediately granted to Edmund, king Henry the Third's younger son, together with Montfort's earldom of Leicester, in whose descendants, the earls of Lancaster and Leicester, it continued, and in the person of Henry the Fourth, who was duke of Lancaster, was absorbed into the regal dignity.

From this time no person has been invested with this high dignity as an heritable possession, or even for his own life, or *quamdiu se bene gesserit;* but only for some special occasion, the office to cease when the business which required it was ended; and this occasion has usually been when a person was to be tried before the House of Peers. On this occasion there is a lord high steward created, who presides, and when the proceedings are closed, breaks his wand, and dissolves the court; but if the trial take place during the session of parliament, though a lord steward is appointed, it is not considered as his court, he having none of the functions of the judge, only voting with the rest as a peer, although he presides.

STEWART, MATTHEW, D.D., a mathematician of North Britain, who attained great distinction by his researches in the higher branches of science, and the success with which he cultivated the antient geometry. He was born at Rothsay, in the Isle of Bute, in 1717; and having received the best education which a grammar-school afforded, he prosecuted his studies in philosophy and theology at the University of Glasgow, into which he was admitted in 1734. Dr. Simson, who then occupied the chair of mathematics in that university, is said to have early discerned the predilection of Stewart for mathematical researches; and his lectures appear to have given his pupil that decided preference for the antient over the modern analysis, which he retained to his death.

On going to reside in Edinburgh, Mr. Stewart attended the lectures of Maclaurin, till, having adopted the church as a profession, he was appointed to the living of Roseneath, in the west of Scotland. In 1747 however, on the death of that mathematician, he was elected to succeed him; and he held the post of mathematical professor in the University till 1772, when his health began to decline. His son, the late Dr. Dugald Stewart, from that time began to assist him by occasionally delivering lectures; and three years afterwards the young mathematician and philosopher was appointed joint professor with his father. In 1775 he retired to an estate in Ayrshire, where he spent nearly all the rest of his life in cultivating science as an amusement. He was elected a Fellow of the Royal Society in 1764; and he died in 1785, being then sixty-eight years of age.

The first efforts of Dr. Stewart in science were to extend the subject of what is called the 'locus ad quatuor rectas' to the powers of any number of perpendiculars drawn to an equal number of lines. While engaged in this pursuit, after his retirement to Roseneath, he discovered most of those propositions which, in 1746, he published under the title of 'Geometrical Theorems.' These, which are mostly porisms, are sixty-nine in number, but five only of them are accompanied by demonstrations. Dr. Stewart is said to have suppressed, for the sake of brevity, the proofs of the others; but several of the theorems were afterwards demonstrated by Dr. Small, and Mr. Lowry has given, in Leybourne's 'Mathematical Repository,' demonstrations of all those which admit of investigation by the processes of the antient geometry.

In the first volume of the 'Essays of the Philosophical Society of Edinburgh,' there is a paper by Stewart containing some propositions founded on a theorem in the fourth book of Pappus; and, in the second volume of the same work, he gave a solution of 'Kepler's problem,' in accordance with the methods of the antients. This he accomplished by the application of a property of curves, from which the approximations may be carried to any degree of accuracy in a series of rapidly converging results.

In 1761 he published his 'Four Tracts, Physical and Mathematical,' in which there is an attempt to investigate the higher parts of mixed mathematics in a manner conformable to the spirit of the Greek geometry. The first tract contains the theory of centripetal forces in a series of propositions, which, admitting the quadrature of curves, are rigorous; and in the remainder of the work Dr. Stewart considers the intricate subject of the perturbations. His design was to carry on the approximations for determining the elements of the orbits according to the method in which Newton, Machin, Walmsley, and other eminent mathematicians had begun the investigations; but the work stops far short of the ends now proposed in the researches of physical astronomy.

In the following year he published a series of geometrical propositions, which are investigated analytically, and afterwards demonstrated by synthetical processes: they are entitled, 'Propositiones More Veterum demonstratæ,' and this designation is said to have been given to them by Dr. Simson. His last work was an 'Essay on the Sun's Distance;' and this problem he endeavoured to treat according to the method of the antients, but the subject is too intricate to admit of their analysis being applied to it, though the work exhibits all the ingenuity which might be expected from the learned author. Making use of the movement of the moon's apsides as an effect of solar perturbation, he determined the parallax of the sun to be 6·9″, and it is now known to be about 8″. Being obliged, in order to diminish the complexity of the investigation, to reject quantities which were supposed to have but small influence on the result, considerable errors exist in the steps; and, except that compensations occurred, the parallax might have appeared to be three times as great as it is in reality. The 'Essay' was much animadverted on by Dawson and Landen during the life of the writer; and since the true parallax of the sun has been ascertained from the transit of Venus, in 1769, it is admitted that no reliance can be placed on the determination of such an element by inductions drawn from the effects of the mutual attractions exercised by the bodies of the solar system.

STEWART, DUGALD, the son of Dr. Matthew Stewart, was born in Edinburgh, on the 22nd of November, 1753. He was educated at the high school of Edinburgh, and the progress he made in classical and mathematical attainments was such as to excite the warmest expectations of future success. In the winter of 1772, having that year attended the course of lectures delivered by Dr. Reid at Glasgow, his love for metaphysical speculation was roused, and he wrote and read to a literary association an 'Essay on Dreaming,' which he afterwards incorporated in his 'Elements of the Philosophy of the Human Mind' (vol. i., chap. v., § 5). He was then in his nineteenth year. But still more decisive was the fulfilment of his early promise a short time afterwards, when, having completed his Glasgow studies, he assumed the charge of the mathematical classes hitherto taught by his father in the university of Edinburgh (Chalmers's *Biog. Dict.*), and on coming of age he was appointed mathematical professor.

He taught with great success until his five and twentieth year, when an occasion presented itself for his resuming his favourite studies under the most advantageous position. Dr. Ferguson, the then professor of moral philosophy at Edinburgh, having been sent as secretary to the commissioners to conclude peace with North America, Dugald Stewart was called upon to fill his place during his absence, which he accepted, and during the session 1778-9, besides teaching his own classes of mathematics, and one on astronomy, he lectured on ethics for Dr. Ferguson; thinking over every morning the subject of lecture for the day, and addressing his pupils extempore. His amiable and elegant manner was much relished, and his lectures gave so much satisfaction, that on the retirement of Dr. Ferguson, in 1785, he was appointed his successor. He had previously had the care of a few private pupils of rank whom he received into his family. He was thirty-two years of age when he entered upon his new professorship. His mind had become enlarged and enriched with a discursive, desultory, but valuable erudition, his opinions had become fixed, and the habitual grace and mildness of his manner had become still more winning from his increasing confidence and facility of exposition. He became very popular. His lecture-room was crowded, his fame spread over Great Britain before he had published anything, and, as Sir James Mackintosh truly remarks, 'without derogation from his writings it may be said that his disciples were among his best works.' His first work therefore came heralded by fame, and it scarcely disappointed. It was the first volume of his 'Elements of the Philosophy of the Human Mind,' which appeared in 1792. The subject was treated with an elegance and eloquence of diction and a richness of illustration which more than compensated the majority of readers for its deficiencies in profundity and logical sequence of ideas; indeed its very faults were helps to its popularity, because it satisfied the current tendency to reaction against the sensualist school, and at the same time made no great demand on the speculative faculty of its reader. The philsophy was that of Reid, but rendered attractive by those arts of composition to which Dugald Stewart paid such fastidious attention; yet of this philosophy, and of Dugald Stewart's works generally, we may say with Professor Cousin, 'it was an honourable protestation of common sense against the extravagancies and extreme consequences of sensualism. But it proceeded no further in its path than did Locke in his. The Scotch philosophy limited itself to the re-establishment of some of the forgotten elements of human nature, and some of the fundamental ideas of reason, which it described such as they now incontestibly appear; but it did not attempt to account for them, nor to ascend to their origin, nor to follow them in their legitimate applications; it had a commencement of psychology, but no regular logic; it had neither a metaphysic, nor a theodicea, nor a cosmology; it had a little of morals and politics, but no system. The merits of the Scotch, as of Locke, are clearness and good sense; their faults are the absence of any speculative ability, the want of comprehensiveness and of rigorous precision.' (*Cours de Philosophie, Intro. à l'Hist. de Phil., Leçon XII.*)

In the following year (1793) Dugald Stewart published his 'Outlines of Moral Philosophy,' a text-book for his pupils; and the 'Life of Adam Smith,' which appeared in the 'Transactions' of the Royal Society of Edinburgh; and which was followed by the 'Life of Dr. Robertson' in 1796, and the 'Life of Dr. Reid' in 1802. They have been subsequently reprinted. His activity was unceasing; and in 1800 he added a series of 'Lectures on Political Economy' to his heavy professional duties, but they were not continued. On several occasions when his colleagues were ill, he gave temporary lectures for them on natural philosophy, logic, and rhetoric. In the winter of 1808-9, from grief at the loss of his younger son, which brought on a severe indisposition, he was obliged to have a deputy to discharge his duties. In the following session, seeing little prospect of recovering his health, he resigned altogether; and in May, 1810, Dr. Thomas Brown, his late assistant, was appointed in his place. Dugald Stewart, having now retired from public life, lived constantly at Kinneill House, on the Frith of Forth, about twenty miles west from Edinburgh, where he devoted himself to the prosecution of his favourite studies. The fruits of his retirement were not slow in manifesting themselves: in 1810 appeared his first volume of 'Philosophical Essays,' in the preface to which he says, 'The state of my health having interrupted, for many months past, the continuation of my work on the human

mind, I was induced to attempt, in the mean time, the easier task of preparing for the press a volume of Essays.'. Yet it is in this work, which he considered the 'easier task,' that he has best proved his claim to the title of a metaphysician, which is noticed both by Sir James Mackintosh and Professor Cousin (*Fragmens Philosophiques*, p. 78); indeed his chief work, as he frankly owns, is rather a collection of such theories pointing towards the common end of throwing light on the structure and functions of the mind, than a systematic treatise, such as might be expected from the title of elements. 'It is in essays of this kind,' says Mackintosh, 'that he has most surpassed other cultivators of mental philosophy. His remarks on the effect of casual associations may be quoted as a specimen of the most original and just thoughts, conveyed in the best manner.' (*Dissertation prefixed to Ency. Britan.*, p. 329.) The 'Philosophical Essays' reached three editions in seven years: the contents of the volume are various and interesting,—on Locke, Berkeley, Influence of Locke on the Philosophy of France; Metaphysical Theories of Hartley, Priestley, and Darwin; on Philological Speculations; on the Beautiful, Sublime, Taste, and Culture of Intellectual Habits. In 1814 the second volume of his 'Elements of the Philosophy of the Human Mind' appeared; but was not so well received, and never, we believe, reached a second edition. In 1815 appeared his celebrated Preliminary Dissertation to the Supplement of the 'Encyclopædia Britannica,' entitled 'A General View of the Progress of Metaphysical, Ethical, and Political Science since the Revival of Letters;' a work for which his discursive reading well fitted him. It enjoys considerable popularity, and chiefly owing to these very qualities, for as a philosophical view of the progress of the metaphysical sciences it is almost worthless. He never once rises to any comprehensive principle. There is no unity in that mass of writing, of criticism, and notes. He never attempts to seize the spirit of each age, and to show how it influenced others. All is isolated. Pleasant and clever as the *adversaria* of some student, but very inefficient if looked on as a treatise or consulted as a history. As a specimen of his carelessness, we may mention the entire omission of Spinoza, a man whose influence on speculative philosophy has been only second to that of his master Des Cartes. His extreme carelessness as to any systematic comprehension of what he was to perform, and his neglect as to arrangement of materials, are, as is remarked by a writer in the 'Quarterly Review,' shown in the author's 'advertisement,' wherein we are told that his original design (as is well known to his friends) was to comprise in ten or twelve sheets all the preliminary matter which he was to contribute to the 'Supplement.' It has now extended to six times this length, and we are informed that he has only discussed one of the three divisions under which he had projected to arrange his subject. We cannot but observe that this fact sufficiently justifies all that we had ventured to say on the desultory and unpremeditated manner in which the work must have been prepared. Yet in the face of this, and of the internal evidence of its desultory nature, Sir James Mackintosh declares this discourse to be 'the most splendid of Mr. Stewart's works.' (*Edin. Review*, Sept., 1816, p. 191. See also a second article by the same hand on this Discourse, *Edin. Rev.*, Oct., 1821, pp. 220-267.)

He remained silent from this period till 1821, when the second part of his 'Discourse' was published, and attracted as much attention as the former, and more hostility, because it was principally occupied with a weak and cavilling attack on Locke and his school. The following year he suffered from palsy, which interrupted his labours till 1827, when he published the third volume of his 'Elements.' In 1828, a few weeks before his death, he published his 'View of the Active and Moral Powers,' by far the least exceptionable of his works. It is more systematic, and contains more new truths than any of his metaphysical writings, and his long acquaintance with the world and with letters enabled him to suggest many obvious but overlooked analyses. It is not a profound, but it is an agreeable book.

Dugald Stewart died on the 11th of June, 1828, in the 75th year of his age, and was buried in the Cannongate churchyard, Edinburgh.

We have also to add to the list of his philosophical writings, an interesting 'Account of a Boy born blind and deaf,' to which no date is affixed.

The admirers of Dugald Stewart style him the Plato of the Scotch School, to which title he has undoubtedly as much claim as Reid has to that of Socrates. But without having himself discovered any important elements which others had overlooked, without even reducing to a system the discoveries of his predecessors, it cannot be denied that his influence was a beneficial one, for he not only strengthened the weaker parts of the ethical doctrines of Ferguson and Reid (Victor Cousin, *Fragmens Philosophiques*, p. 78), and rendered the metaphysical doctrines of Reid less objectionable and confused, by substituting the 'laws of human thought or belief' for the absurd 'common sense' or 'instinct' which were by Reid assumed as final arbiters, but he also adorned the school by every charm of mild enthusiasm and elegance of diction, and rendered the study attractive, by enlisting in its cause the aid of much elegant literature and an exquisite taste, at least such as was in those days regarded as exquisite, when an exclusive regard to diction was the exercise of the most refined taste. 'Few writers,' remarks his friendly critic, 'rise with more grace from a plain groundwork to the passages which require greater animation or embellishment. He gives to narrative, according to the precept of Bacon, the colour of the time, by a selection of happy expressions from original writers. Among the secret arts by which he diffuses elegance over his diction, may be remarked the skill which, by deepening or brightening a shade in a secondary term, by opening partial or preparatory glimpses of a thought to be afterwards unfolded, unobservedly heightens the import of a word, and gives it a new meaning without offence against old use.' (*Edin. Rev.*, 1816.) Sir James Mackintosh afterwards repeated this verbatim in his 'Preliminary Dissertation,' p. 321; so that it may be regarded as his deliberate judgment. A want of depth, indeed of speculative power, is everywhere manifested in Stewart's writings, and the most glaring contradictions to his own principles impeach his logical rigour; but the style and his calm earnestness always render his works interesting to students.

(*Ency. Brit.*, art. 'Stewart;' Sir J. Mackintosh's *Preliminary Diss. to Ency. Brit.*)

STEWARTON, a town in Ayrshire, 18 miles south-south-west from Glasgow, on the road to Kilmarnock, from which it is distant five miles. The parish is in the district of Cunningham: and extends ten miles in length from north-east to south-west, and from three to four in breadth. The area is about 10,145 acres. There are no lofty hills; but the land slopes from north-east to south-west, in which direction the Annock-water, which drains the parish, flows. Freestone and limestone are dug, but there is no coal. The population in 1831 was 4503, viz. 2234 in the town, 735 in the suburbs, and 1534 in the rural district; a later calculation (1836) makes the population 4562. The town of Stewarton is on the north bank of the Annock-water: it has risen to importance only since the extension of manufactures of late years: it has however long had a manufacture of Highland bonnets, of which it is now the chief seat, and in connection with which are mills for carding and spinning wool. The manufacture of carpets has also been introduced, as well as the weaving of silks, muslins, linens, and damasks. The market is on Thursday, and there are six yearly fairs. The church is in the centre of the town: it has sittings for 1400 persons. There are meeting-houses for the dissenters of the United Secession Church and for Burghers. A small Independent congregation meets in the town-house. The parish is in the synod of Irvine and presbytery of Glasgow and Ayr. There were in 1834 ten schools in the parish, viz. the parish school, with an average attendance of about 27, viz. about 14 boys and 13 girls, and nine others: the whole number of children under 15 years, who had learned or were learning to read, was 316; to write, 275.

(Chambers's *Gazetteer of Scotland*; *Parliamentary Papers*.)

STEYER, the capital of the circle of the Traun, in Upper Austria, is situated at the conflux of the Steyer and the Enns, in a beautiful valley, surrounded with hills and lofty mountains. It is situated in 48° 4′ 15″ N. lat. and 14° 20′ E. long., 92 miles south of Vienna, and 16 miles south-south-east of Linz.

Steyer has nine suburbs and five gates. The town is on the left bank of the Enns, which separates it from the suburb Ennsdorf, as the Steyer does from Steyerdorf, with which two suburbs it is connected by two bridges. From the latter suburb, almost at the confluence of the two rivers, there is a most delightful prospect. On a steep rock, on the right bank of the Steyer, the castle of Prince Lamberg stands on

the site of the old castle, which was built between 980 and 990, and was for many centuries the residence of the princes of Styria, till they removed to Grätz. Steyer is a neat and a pretty large town, with above 10,000 inhabitants. Many of the streets are narrow and crooked. There are three squares: the principal square is very large and ornamented with two fountains. Many of the houses are built in the Italian style, with flat roofs, galleries, and statues, especially in the great square. Among the public buildings the most worthy of note are the church of the Dominicans (in the great square), with antient painted glass windows; the antient parish church, a massy Gothic edifice, with a lofty tower, from which there is a fine prospect over the town and the country, to the distant summits of the Alps; the old and the new town-house, St. Michael's church, formerly belonging to the Jesuits; the theatre, the barracks, and four hospitals. Steyer is the seat of the court of justice of the circle of the Traun, and of a superior mining-court. There are a normal and four other schools. Steyer has some woollen and cotton manufactures, but it is chiefly remarkable for those of iron, which employ above 12,000 workmen in the town and neighbouring country. The principal establishment is a manufactory of fire-arms on account of government; of the numerous other articles the chief are sword blades, daggers, bayonets, files, razors, awls, to which some writers add scythes, and kitchen utensils of all kinds; but Mr. Jenny (who, in his description of the town, includes them in his list) gives a note at the end of his work, in which he says that no such articles are manufactured here. Steyer is one of the most important and flourishing manufacturing towns in Austria, and has a very extensive trade, especially to Turkey and the Levant. In the sixteenth century Steyer was the richest town in Austria next to Vienna. It has several times suffered severely by fire.

STEYERMARK. [Styria.]

STEYNING. [Sussex.]

STICKLEBACK, the common name in this country for certain small fishes which constitute the genus *Gasterosteus* of Linnæus. This genus is arranged by Cuvier with the mail-cheeked Acanthropterygians (*Loricati*), and is distinguished by the following characters:—Anterior dorsal represented only by free spines; body generally scaleless, but protected more or less at the sides by shield-like plates; ventrals reduced to a single spine; head without spines or tubercles; branchiostegous membrane with three rays.

Several species of stickleback are found in the ponds and streams of this country, and one species is found in the salt water; they are very active and voracious, and live upon aquatic insects and worms.

The most common species is the three-spined stickleback (*Gasterosteus aculeatus*, Linn.), which is distinguished by the body being protected at the sides with shield-like plates, and the possession of three spines on the back. It is of an olive colour above and silvery white beneath, and varies from two to three inches in length. In the breeding season the males assume a pink hue on the under parts of the body, and the general colouring of the upper parts is brighter, and often green. According to Bloch, this species spawns in April and June; and according to Cuvier, in July and August.

The number of scaly plates varies in the sides of the body, and is supposed by some authors of high authority to afford specific characters. The following are the principal varieties or species established by Cuvier and Yarrell chiefly upon this character.

G. trachurus, rough-tailed stickleback (Yarrell, *Brit. Fishes*, vol. i., p. 76). The scaly plates extending the whole length of the sides; in number about thirty.

G. semiarmatus, half-armed stickleback, Yarrell. Lateral plates extending to a vertical line joining the vent and commencement of the soft dorsal; in number from twelve to fifteen.

G. leiurus, smooth-tailed stickleback, Yarrell. Lateral plates extending only as far as the ends of the rays of the pectoral fins, where these last are laid back.

G. brachycentrus, short-spined stickleback, Yarrell. Lateral plates not extending beyond the pectorals; dorsal and ventral spines very short.

The above are regarded as varieties of the *Gasterosteus aculeatus*, Linn., by Mr. Jenyns, who observes that that species 'is subject to great variation, not only in the number of lateral plates, but in several other less obvious respects. The former may occasionally be found of every intermediate number between that which characterises the *G. leiurus*, Cuv., and that which appears in the *G. trachurus* of the same author. This number moreover is sometimes found constant in specimens which differ remarkably in other respects; at other times varying, when all other characters remain the same. From these circumstances combined, I feel satisfied that the above are mere varieties, notwithstanding the high authorities on which they stand recorded as distinct species.' (*Manual of British Vertebrate Animals*, p. 349.)

A writer in the 'Magazine of Natural History,' vol. iii., p. 329, relates some interesting observations illustrative of the habits of these little fishes whilst in confinement in a tub. 'When a few are first turned in, they swim about in a shoal, apparently exploring their new habitation. Suddenly one will take possession of a particular corner of the tub, or, as it will sometimes happen, of the bottom, and will instantly commence an attack upon his companions; and if any one of them ventures to oppose his sway, a regular and most furious battle ensues: the two combatants swim round and round each other with the greatest rapidity, biting and endeavouring to pierce each other with their spines, which on these occasions are projected. I have witnessed a battle of this sort which lasted several minutes before either would give way; and when one does submit, imagination can hardly conceive the vindictive fury of the conqueror, who, in the most persevering and unrelenting way, chases his rival from one part of the tub to another, until fairly exhausted with fatigue. They also use their spines with such fatal effect, that, incredible as it may appear, I have seen one during a battle absolutely rip his opponent quite open, so that he sank to the bottom and died. I have occasionally known three or four parts of the tub taken possession of by as many other little tyrants, who guard their territories with the strictest vigilance; and the slightest invasion invariably brings on a battle. These are the habits of the male fish alone; the females are quite pacific; appear fat, as if full of roe; never assume the brilliant colours of the male, by whom, as far as I have observed, they are unmolested.'

Dr. James Stark discovered near Edinburgh a new species of the present genus, which greatly resembles the common species, but is rather smaller, and has four spines on the back. It is the *G. spinulosus* (four-spined stickleback) of Yarrell and Jenyns.

A still smaller species—the ten-spined stickleback (*G. pungitius*, Linn.)—is distinguished, as its English name implies, by the possession of ten spines on the back, and these are short and of equal length.

This, as well as the other species of the genus, is occasionally found in the salt-water. It appears to be pretty generally distributed throughout England.

Lastly may be noticed the fifteen-spined stickleback (*G. spinachia*, Linn.), which is also found in England, a comparatively large species, being five or six inches in length, of an elongated and slender form, and having the snout much produced. The fifteen spines on the back are small and short; the fins are proportionally large.

This species appears to be confined to the salt-water, and feeds upon small crustacea, as well as the eggs and fry of other fishes. It constitutes the subgenus *Spinachia*, and is the *Spinachia vulgaris* of Fleming.

STIFEL, or STIFE'LIUS, MICHAEL, a celebrated German algebraist of the sixteenth century, was born at Eslingen, in Saxony; the year of his birth is not known with certainty, but, according to Vossius, it was in 1509. He was a Lutheran clergyman, and a contemporary of Cardan; and it may be mentioned as a remarkable circumstance, that algebra should at the same time have been diligently studied both in the north and south of Europe, apparently without any intercourse being maintained among the persons who were engaged in the pursuit. Of the men who distinguished themselves in the north may be mentioned Rudolph, Stifel, Scheubel, and Stevin; and among those of the south were Ferreus, Cardan, Tartaglia, and Ferrari. The notation employed in Germany differed in some respects from that which was used in Italy; and from this circumstance it has been imagined that the ma-

thematicians of the two countries obtained the first principles of the science from distinct sources.

Stifel's first publication was a treatise on algebra, in German; but in 1544, that is, a year before Cardan's rule concerning cubic equations came out, he published at Nuremberg, in Latin, the 'Arithmetica Integra,' which is his principal work. It is divided into three books, of which the first is a treatise on arithmetic; the second, a commentary on Euclid's tenth book; and the third, a treatise on algebra. He appears to have been the first who used the signs + and − between quantities, in order to indicate addition and subtraction: the first power of the 'res' (the unknown quantity) in an equation he designates the root of the equation, and represents it by a letter of the alphabet: he employs the initial letters of the words, and also the numbers 2, 3, &c., both positive and negative, to denote the corresponding powers of the quantities to which they are affixed, and he calls the numbers so applied the exponents of the powers, as they are called at present. He uses the radical sign to designate a root, but he has no mark to denote equality, the word itself being employed for that purpose.

In one of the chapters he demonstrates, from the nature of arithmetical and geometrical progressions, that the addition and subtraction of the exponents of powers correspond to the multiplication and division of the numbers whose powers they indicate; and this may be considered as one step towards the discovery of logarithms: but in expressing the exponents of the higher powers of quantities, he combines those of the lower powers by multiplication instead of addition: this last method was that of Diophantus. Thus, in order to denote the sixth power of any quantity, he uses terms indicating the square of the cube, instead of terms expressing the sum of two third powers. His method of resolving quadratic equations is by completing the square, as is done at present.

He treats at some length of what are called triangular numbers, that is, of adjacent columns of numbers constituting various progressions: thus the numbers in the first column may form an arithmetical progression beginning with 1, and having unity for the common difference; the second column may begin with 3, and the successive differences of the numbers may be 3, 4, 5, &c.; the third column may begin with 10, and the successive differences may be 10, 15, 20, &c., and so on, the head of each column being opposite to the like number in the adjacent column preceding it. He explains the use of the table in discovering the coefficients of the several terms in any powers of a binomial quantity, and in extracting the roots of numbers; and it may be observed that such tables have since been made to serve several other useful purposes in mathematics.

Stifel wrote also a treatise on the calendar, and a tract on 'magic squares.' Like many other learned men of that century, he appears to have spent much time in studying the 'Apocalypse,' and he is said to have predicted that the end of the world would take place in the year 1553. One of his countrymen, also a mathematician, had previously assigned for the time of that event the year 1524; and in Britain, the celebrated Napier found out that it would occur between the years 1688 and 1700.

Stifel died at Jena, in 1567.

STIGAND, a Saxon prelate, in great favour with Edward the Confessor, who made him bishop of Elmham, or more properly of the East Angles, the seat of which bishopric is now at Norwich. This was in A.D. 1043. Four years after he was translated to Winchester; and in 1052 the archbishop of Canterbury, Robert 'Gemeticensis,' being driven into exile, but not formally deposed, Stigand was made archbishop. This was considered an intrusion and irregularity: but the scandal was the greater, inasmuch as Stigand retained his bishopric of Winchester, holding at the same time both those high dignities. He is charged, in consequence of this, with having been inordinately avaricious and ambitious; but this defence has been made for him, that his hold was firmer on the bishopric of Winchester than on the archbishopric, from which he might have been removed had Robert returned. It is said to have been by a stratagem, of which he was the contriver, that the people of Kent obtained from the Conqueror a ratification of some of their antient customs. The Conqueror disliked him; refused to allow him to place the crown on his head; and forced him to accompany him when he returned to Normandy. Finally, the king prevailed upon the pope to send three cardinals to England to inquire into the conduct of Stigand: and several things being proved against him, he was deprived of his dignities and degraded from the clerical order. He was also condemned to perpetual imprisonment; but soon died, being, as is said, starved to death, either by the cruelty of others or by his own voluntary act. He died at Winchester, and was buried there. Lanfranc succeeded him.

STIGMA, in Botany, one of the three parts into which the central organs of the flowers called carpels are divided. The term pistil is applied to these organs, whether there is but one or many of them, or whether they are united or separate. The carpel consists of three parts: the *ovary* or germen, generally of a spherical form, and hollow, containing the ovules; the *style*, an elongated organ, formed of a continuation of the tissue of the ovary, possessing a canal in communication with the interior of the ovary; and the *stigma*, which is the point or summit of the style. The carpels, like all other parts of the flower, are modifications of the leaf, and examples of their reversion to their normal form are not unfrequent. This is well seen in the double cherry, in which the pistil often appears as a little leaf in the centre of the flower. The blade of the leaf corresponds to the ovary of the carpel; the midrib, which is elongated, to the style; and the stigma is nothing more than a secreting surface at the point of the style, communicating with the interior of the ovarial leaf. The carpel presents two sutures, called *dorsal* and *ventral*. The first of these corresponds with the midrib of the leaf, and the latter with the folded margins. The ventral suture is always opposite the axis of the plant, and is the point from which the *placenta* is developed, to which the young ovules are attached.

When there is only one carpel in the flower, it is called a simple pistil; but when there are several carpels, they are called a compound pistil. The carpels of a compound pistil may be either united or separate. When they are united, they are called by Lindley *syncarpous*. This union may occur between the ovaries only, leaving the styles distinct, as in *Nigella damascena*: or the ovaries, styles, stigmas, and all may be united, forming one body, as in the tulip. When the carpels are all separate, as is seen in Caltha, Ranunculus, &c., the pistil is said to be *apocarpous*.

The *style* is not at all essential to the existence of the carpel, and is frequently absent. When present, it is composed of just the same tissues as the ovary, which in most cases consist of vascular surrounded by cellular tissue. The style varies in form and size; sometimes it is flat, as in the Iris and Canna, but is mostly cylindrical and filiform. It generally proceeds from the apex of the ovary, but in some cases, from an alteration in the position of the ovary, it proceeds from other parts besides the apparent apex, as from the side in Alchemilla, and from the base in Lamiaceæ and Boraginaceæ. The length of the style varies very much; in some plants, as in Colchicum, it is seven or eight inches long, whilst in the Nymphæaceæ and Papaveraceæ it can hardly be said to exist at all. The canal of the style was first discovered by Malpighi. It is a continuation of the cavity of the ovary, and terminates in the surface of the stigma. This canal varies in extent in different plants, in some being very narrow, and in others very wide. It is lined with a peculiar kind of cellular tissue, having a papillary character, and is covered with a viscous secretion. It is called by Brongniart *tissu conducteur*, or conducting tissue, on account of its supposed office in conducting the pollen tubes from the stigma to the ovule.

The style is often covered with hairs, which, on account of their supposed office of clearing the pollen from the cells of the anthers, have been called *collectors*. Sometimes these hairs are united together into a kind of cup around the stigma, as in Goodeniaceæ, when they form what is called an *indusium*.

The stigma is composed of the same kind of tissue as the interior of the canal of the style, but has a more spongy appearance. Its papillary character also is more evident, and the little swellings on its surface are often called papillæ. These papillæ become less evident as the canal of the style approaches the ovary. The stigma assumes a variety of forms, the distinction of which is often of importance in systematic botany. These forms depend principally upon the tissue of which its surface is composed. Sometimes the papillæ are developed into little hairs, as is seen in the stigma of *Urtica urens*. In other cases it is perfectly smooth, as in Nymphæaceæ. In rhubarb it is composed of

three flat orbicular disks. In grasses it is in the form of a tufted hairy body like a little brush. In Mimulus it has two lips which have the power of contracting, and in Clarkia it consists of four broad lobes. In Orchidaceæ it has a structure in accordance with the anomalous character of all the parts of the flower in these plants; it consists of an oval humid space which occupies the middle of the central column, and is covered with a thick viscous secretion. In some cases however the stigma is not distinguishable from the style, as in Asclepias and Tupistra.

The position of the stigma is sometimes anomalous. As it forms the apex or point of the carpellary leaf, it ought always to be alternate with the placentæ, which are formed at the margins of the leaf, but in Cruciferæ the stigmata are opposite the placentæ. This may be explained in two ways. Dr. Lindley supposes that in this order there are originally four carpels, two of which being abortive, the stigmata are left opposite the placentæ. Brown on the contrary supposes that the stigmata are originally two-lobed, and that the lobes have united on each side, and thus obtained their abnormal position.

For the function of the stigma see IMPREGNATION, and POLLEN.

STILAGINA'CEÆ, a small natural order of plants belonging to the rectembryose group of apetalous Exogens. They are trees or shrubs, with alternate, simple, stipulate leaves, the stipules being deciduous. The flowers are unisexual, mostly seated on amentiform spikes or racemes. Calyx 3-5 parted; stamens 2 or more, arising from an enlarged receptacle with capillary filaments and 2-lobed anthers dehiscing transversely; ovary superior, stigma sessile; fruit a drupe with one seed, which is pendulous; the embryo is green, lying in the midst of fleshy albumen.

The species of this order are all of them natives of the East. In its relations this order is obscure. It has some resemblance to Urticaceæ, from which it is distinguished by its enlarged disk, its peculiar anthers, and unelastic filaments. In these characters it resembles Henslowiaceæ, but they differ from this order in having but one carpel and a single seed. Many of the fruits of this order have a pleasant subacid flavour, and are eaten by the natives of the East Indies.

STILA'GO, a genus of trees sometimes united with, at other times separated from, the genus Antidesma, belonging to the natural family of Antidesmeæ, which by some botanists is called Stilaginaceæ. The species are few in number, forming shrubs and moderate-sized trees, which are found in Madagascar and Mauritius, as well as in some of the Indian islands, and in India, where the species extend even to northern parts. The genus is characterised by having diœcious flowers, the male having a 3- or 5-parted perianth. Stamens 2, 3, or 5, inserted in an annular disk with the rudiment of an ovary. The female flower has the perianth of the male, and the disk surrounding the base of the ovate single-celled ovary. Ovules 2, pendulous from the apex of the cell. Stigma sessile, 3 to 5-rayed. Drupe one-seeded, crowned by the stigma, with the nut rugose both inside and out. Albumen fleshy, scrobiculate. Cotyledons foliaceous. Embryo inverse. The flowers are arranged in axillary catkin-like spikes. The leaves of Antidesma alexiteria are employed in the Isle of France as an antidote against snake-bites. Cordage is made with its bark, as well as with that of A. zeylanica in Ceylon. The small fruits of both species are eaten and preserved: the fruits of A. pubescens (Stilago), Bunias, and Diandra are eaten by the natives of India.

STILBA'CEÆ, a small natural order of plants belonging to the nucamentose group of monopetalous Exogens. They are small shrubs, with the habit of a Phylica or a fir, having whorled close narrow entire leathery rigid leaves, articulated at the base and without stipules. The flowers are arranged in dense spikes at the points of the branches; they are sessile, each having three bracts at its base. They differ but little from Selaginaceæ except in their 2-celled anthers, their erect ovules, and in the want of an hypogynous disk. Kunth, who formed this order, points out also its relation to Globulariaceæ, and places it intermediate between that order and Selaginaceæ. The order consists of only two genera, *Stilbe* and *Campylostachys*, both of which are natives of the Cape of Good Hope. Their properties are not known.

STI'LICHO, FLAVIUS, was of Vandal origin, and his father had been a military officer in the reign of Valens. Concerning his early life and youth we know nothing beyond the vague eulogies of Claudian (*De Laud. Stilich.*, i. 42, &c.). According to the poet's account he distinguished himself in early life in a manner which announced his future greatness. He was of an unusually tall stature, and his appearance commanded respect. When he had scarcely arrived at the age of manhood, he was sent by the emperor Theodosius to negotiate a treaty with Persia. He discharged his duties as ambassador, and maintained the dignity of the Roman empire; and after his return the emperor rewarded him with the hand of Serena, his niece, whom he had adopted as his daughter. (Claud., *Laus. Seren.*, *De Laud. Stilich.*, i. 71, &c.) Stilicho was raised from one high office to another, until at last he became master-general of all the cavalry and infantry of the Western empire. In all his military undertakings he set a noble example of honesty, integrity, and valour, combined with wisdom. Even his enemies owned that he was inaccessible to bribes. The distinctions which were conferred upon him excited the envy and hatred of Rufinus, to whom Theodosius had entrusted the administration of the East, and Stilicho would perhaps have fallen a victim to his intrigues, if Serena had not protected her husband at the court while he was at the head of the armies of Rome.

In the year A.D. 393, when Theodosius made war upon Eugenius, who with an army of Franks and Alemanni occupied the passes in the Alps between Pannonia and Italy, he placed Stilicho and Timasius at the head of the Roman forces. Eugenius was defeated and slain in the year following in a battle near Aquileia. (Oros., vii. 35; Gregor. Turon., ii. 9.) Before his death Theodosius divided the empire between his two sons, Arcadius and Honorius, the former of whom, then eighteen years old, was to govern over the East under the guidance of Rufinus; and the latter, only eleven years old, over the West, under the guardianship of Stilicho. According to the flattering account of Claudian, the emperor entrusted to Stilicho alone the care of his two sons and of the empire. (Zosim., v. 1.) Young Honorius trifled away his time in the palace of Milan, and Stilicho was in reality the sovereign of the Western empire. Stilicho has been blamed for having neglected the education of Honorius, but there is not the slightest evidence of any talent or intellectual capacity in the prince. After the death of Theodosius, Stilicho hastened through Rhaetia and down the Rhine, inspected the country and the garrisons, and renewed the treaties with the Alemanni and Franks. With the exception of Count Gildo in Africa, who even during the last years of the reign of Theodosius had endeavoured to make himself independent in his province, the whole of the Western world acquiesced in Stilicho's authority. Rufinus was the enemy from whom Stilicho had to fear most. Great numbers of the troops who had been employed in the war against Eugenius, were still in Italy, and Rufinus, anxious that they should be withdrawn from that country, is said to have invited Alaric, king of the Visigoths, to invade Thrace and Moesia, which would oblige Stilicho to send these troops to the East. Stilicho appears to have entertained the design of uniting the two empires again, and he determined to lead the troops to Constantinople himself. But Rufinus, alarmed at the approach of his rival at the head of an army, induced the emperor Arcadius to declare that Stilicho should be considered an enemy of the empire if he advanced any farther. Stilicho retired, but secretly he determined to revenge himself upon Rufinus. His soldiers were attached to him, and he could place full confidence in them; he left the command to Gaina, a Gothic prince, and at the same time gave him instructions to seize Rufinus, and to put him to death. The soldiers were easily persuaded to lend their assistance in the execution of this design. When Gaina and his army had reached Constantinople, and Rufinus with the emperor was reviewing the troops, he was surrounded by the soldiers and cut down on the spot (November, 395). The people of Constantinople rejoiced at their deliverance from the oppressor. Stilicho thus got rid of his mortal enemy at Constantinople, but a new one sprang up in his place. Eutropius, a eunuch, gained the unlimited confidence of Arcadius, and Gaina, the faithless barbarian, also deserted the cause of Stilicho, and was rewarded for it with a high office in the Eastern empire. These two new enemies of Stilicho, as long as they were united, left no means untried to deprive their adversary of the confidence of Honorius, and of the attachment of the subjects of the Western empire. His life was repeatedly endangered by assassins, and a decree was issued by the senate of Constan-

tinople, by which he was declared an enemy of the empire. Stilicho was wise and moderate enough not to involve the two empires in a civil war on this account.

Alaric, who had in the meanwhile invaded, ravaged, and plundered Greece, had penetrated as far as Peloponnesus in A.D. 396. Stilicho went with a fleet to Peloponnesus; but Alaric escaped with his Goths, was received by Arcadius into the service of the East, and made commander of all the forces of Illyricum, as far as it belonged to the Eastern empire. (Zosim., v., 7; Claudian, *De Bell. Get.*) On his return to Italy, Stilicho began, in 397 A.D., his preparations for the war against Gildo in Africa. Thinking that his presence was necessary in Italy, partly to protect the northern and eastern frontiers, and partly to provide Italy with supplies of corn, he entrusted the command to Gildo's own brother Mascezil, who was the bitterest enemy of his brother. The army of Mascezil amounted to about 5000 men, but they were mostly veterans who had served under Eugenius. Gildo had assembled a numerous undisciplined body to repel the attack, but it was routed, and Mascezil gained an almost bloodless victory. Gildo was seized, and sentenced to death, with a great number of his adherents. (Oros., vii., 36; Claudian, *De Bell. Gildonico.*) This important campaign was completed in one winter. Soon after his return to Milan, Mascezil, while riding by the side of Stilicho, was thrown from his horse into the river and drowned, and the enemies of Stilicho spread the report that by a peculiar look he had prevented the attendants from saving the unfortunate prince. According to other accounts, Mascezil was put to death for having violated the sacred character of a church. Soon after these events Honorius was married to Maria, the daughter of Stilicho and Serena. (Claudian, *De Nupt. Honor. et Mariæ.*)

Alaric had availed himself of his position in Illyricum to strengthen himself, and secretly matured his designs, while externally he kept up a good understanding with the courts of the East and of the West. At length, in A.D. 400, he set out on his march against Italy. The immediate cause of this invasion is not known. When Alaric advanced towards Aquileia, all Italy was in consternation, and the counsellors of Honorius advised him to seek a refuge in some foreign land. Stilicho alone did not share their despair. But the difficulty was to raise an army, as most of the troops were engaged in Rhaetia. Stilicho hastened thither, and was soon enabled to send the troops from Rhaetia to Italy. He also drew reinforcements from Gaul and other parts of the empire, and engaged some of the nations with whom he made peace to assist Honorius. Alaric appears to have been checked in his progress by the siege of Aquileia, and to have withdrawn towards the Danube to reinforce himself; but before Stilicho returned from his expedition, in which he assembled his forces, Alaric, in 402, advanced towards the imperial residence of Milan. Honorius fled to Asta in Liguria, where he was besieged by the Goths, and would have fallen into their hands if Stilicho had not arrived just at the critical moment with his army. He forced his way through the camp of the enemy, and saved his sovereign. The Goths withdrew, and pitched their camp near Polentia, and while they were engaged here in celebrating the feast of Easter, Stilicho attacked them unexpectedly in their camp. A bloody struggle ensued, in which the barbarians were defeated (403). The whole camp of Alaric, and even his wife, fell into the hands of the Romans. Claudian (*De Bell. Get.*) compares this victory with that of Marius over the Cimbri, although from other sources we learn that Stilicho gained the victory with great loss, while some authors even state that he was defeated. These latter accounts are the more probable, as Alaric marched from Polentia towards the Apennines to attack Etruria and Rome. This induced Stilicho, according to Claudian, to enter into negociations for peace with Alaric, as he was unwilling to stake the existence of the empire on another battle. A peace was concluded, and Alaric retreated across the river Po. Stilicho however, mistrusting the Goth, sent a small corps of observation after him, and appears to have carried on a secret correspondence with some of the Gothic chiefs in Alaric's army, so that he was informed of all that was going on. Alaric intended on his march to make himself master of Verona, but when he approached this city he found himself suddenly surrounded by the imperial troops whom Stilicho had sent thither. Alaric is said to have lost here as many of his men as at Polentia, and he himself was nearly made a prisoner. Stilicho concluded a fresh treaty with him, and allowed him to depart from Italy.

After the delivery of Italy, Honorius and Stilicho solemnized a triumph at Rome with great pomp and splendid games. The hostile machinations against Stilicho were still going on at the court of Constantinople, and he saw no better way to secure himself against them than by entering into an alliance with Alaric and engaging Honorius in a war with his brother. Stilicho intended to acquire for his sovereign possession of the eastern part of Illyricum, and Alaric was to assist him in carrying out this design, on condition that he should receive certain subsidies. (Zosim., v. 26.) The execution of these plans was interrupted, in A.D. 405, by the invasion of Radagaisus, who entered Italy at the head of several Germanic tribes, which formed an army of above 200,000 men. The safety of Italy rested again in the sword and the wisdom of Stilicho; he again drew all the military forces from the provinces to Italy, and reinforced their numbers by fresh levies. But with all his exertions he could not raise more than 40,000 men, exclusive of some foreign auxiliaries consisting of Huns under Uldin and Goths under Sarus. Radagaisus and his hordes crossed the Po and the Apennines, and marched into Etruria. Stilicho assembled his forces in the neighbourhood of Pavia. Many cities were pillaged and destroyed by the barbarians, but the siege of Florence checked their progress towards Rome. At the moment when Florence was on the point of being reduced, Stilicho surrounded the barbarians, who were encamped on the heights of Fæsulæ, with strong lines of circumvallation, while plentiful supplies were introduced into Florence. The enemy was finally reduced by famine, thirst, and disease. Radagaisus fell into the hands of Stilicho, and was put to death, and his barbarians were sold as slaves. (Oros., vii. 37; Zosim., v. 26; Augustin., *Serm.* cv., 10; *De Civit. Dei*, v. 23; Marcellin. *ad A*, 406.)

The province of Gaul, from which Stilicho had been obliged to withdraw the garrisons, was invaded and ravaged, about the end of A.D. 406 and the beginning of 407, by Vandals, Alani, Suevi, Burgundians, and other Germanic tribes. In Gaul these barbarians were opposed by Constantine, a man who had shortly before been raised from the condition of a common soldier to the rank of emperor by the soldiers in Britain, and now made himself master of Gaul and Spain by entering into a league with some of the barbarians. Stilicho indeed sent Sarus, the Goth, to Gaul, but without success, and Honorius was for a time obliged to leave the rebel in the undisturbed possession of his conquests.

Alaric in the mean time became impatient, and having advanced with his army as far as Aemona on the frontiers of Italy, he sent ambassadors to Ravenna to demand the promised subsidies. When the ambassadors arrived, Stilicho left them at Ravenna and went to Rome, where Honorius was then staying. Stilicho, who was convinced that it was dangerous to make such a formidable neighbour as Alaric an enemy, was willing to continue the peace with him, and to grant his requests. He laid the matter before the Roman senate, which, with a spirit not unworthy of antient Rome, declared that the demands of the Goth should not be complied with, and that destruction would be preferable to such disgrace. The influence however of Stilicho and his party, whose object only was to preserve Italy from new devastations at a moment when Gaul was in the hands of a rebel and of barbarians who might easily be induced to march southward, was so great, that nearly all the senators at length were obliged to give way, and 4000 pounds of gold were granted to Alaric under the name of a subsidy. (Zosim., v. 29.) The desire of Stilicho to maintain peace with Alaric was interpreted by his enemies as a treacherous partiality for the enemy of the empire, and all the calamities under which Italy had been suffering were imputed to Stilicho. Even Honorius now began to fear and suspect his minister; and this feeling was fostered by a cunning hypocrite of the name of Olympius, whom Stilicho himself had introduced to the court, and who had gained the confidence of the emperor.

In May, 408, Arcadius died, leaving a son, Theodosius, eight years old. Honorius proposed a journey to the East to regulate the administration. Stilicho represented to him the difficulties and dangers of such an undertaking, and in consequence it was determined that Stilicho should go to Constantinople. An army, which was to march against Constantine, was assembled near Pavia, and Honorius went thither to inspect it, while Stilicho was making preparations

at Bologna for his departure. The eunuch Olympius represented to the emperor that Stilicho was conspiring with Alaric, that he intended with his assistance to raise his son Eucherius to the throne, and that it formed part of their design to restore paganism in the empire. (Olympiodorus, *ap. Phot. Cod.*, 80.) He also contrived to influence the soldiers at Pavia, who revolted, and on a given signal killed several of their principal officers, who were represented to them as the friends of Stilicho. As soon as the intelligence of the revolt at Pavia had arrived, Stilicho's friends advised him to march against his enemies; but he hesitated till it was too late. His friends, for the most part barbarians, left him with indignation at his want of resolution. At midnight, Sarus, the faithless Goth, made an attack upon Stilicho's tent, and cut down his guards. Stilicho escaped to Ravenna, and took refuge in a church. He was treacherously induced to come out, and as soon as he had left the threshold he was put to death by Count Heraclian, who was waiting for him with a band of soldiers, on the 23rd of August, 408. His family and his friends were persecuted, and many of them put to death. (Zosim., v. 34.)

The history of Stilicho has come down to us in a manner which scarcely enables us to choose a due medium between the extravagant praise of Claudian and the charges of his enemies, or of such writers as were obliged to join in the general clamour that was raised against him after his fall.

(Mascow, *History of the Antient Germans*, vol. i., book viii., sect. 2, 19, English translation; Gibbon, *History of the Decline and Fall of the Roman Empire*, chap. 29 and 30; C. F. Schultz, *Flavius Stilicho, ein Wallenstein der Vorwelt, ein Beitrag zum letzten Theile der Röm. Geschichte*, Altenburg, 1805, 8vo.)

STILL. [DISTILLATION.]

STILLING, JUNG JOHANN HEINRICH, a celebrated German Pietist, born at Grund, in Westphalia, 1740. His father Wilhelm Jung was a charcoal-burner, to which trade he was also destined, but circumstances favouring his becoming a tailor, he chose that business, though he soon relinquished it for a situation as teacher at a school. Dissatisfied with this, he returned to tailoring, and continued it till several of the gentry befriended him, and took him as private tutor to their children. He contrived to save a little money, which enabled him to pursue his studies, and went in consequence to Strassburg, and studied medicine there. It was here he became acquainted with Göthe, who took a great liking to him, and has sketched his character with great fondness in several passages of the 'Dichtung und Wahrheit' (books ix. and x.). It was at Göthe's suggestion that he wrote his interesting autobiography (*Lebensgeschichte*), to whom he had often related it. Stilling practised as physician for some time in Eberfeld, and in 1778 was appointed professor at the Kameralschule of Lautern, and in 1787 at that of Marburg, and in 1803 at that of Heidelberg. He died in Karlsruhe, 1817.

As a physician, Stilling's great talent was in diseases of the eye, and he is said to have restored upwards of 2000 persons to better sight. As a writer, he was very popular, and the sect of Pietists in Germany (somewhat similar to our Methodists) look up to him with great affection. 'The great element of his character was an invincible and intense faith in God and an immediate providence, ever at hand in the time of trouble, and which momently preserved man from evil.' The most celebrated of all his works is the 'Theorie der Geisterkunde,' which we believe has been translated into English. A complete edition of his works was published at Leipzig, in 1835, in 13 vols. 8vo., edited by Dr. J. Grollmann.

(Stilling's *Lebensgeschichte*; Göthe's *Dicht. und Wahrheit*; *Conversations Lexicon*.)

STILLINGFLEET, EDWARD, son of Samuel Stillingfleet, was born at Cranbourn, in Dorset, on the 17th of April, 1635. He was educated at the grammar-schools of Cranbourn and Ringwood, and at St. John's, Cambridge. He entered the college in 1648, and obtained a fellowship in 1653. After taking his degree of M.A. he was private tutor successively in the families of Sir Roger Burgoin, at Wroxhall, in Warwickshire, and of the Hon. Francis Pierrepoint, of Nottingham. Here he began his 'Irenicum.' In 1657 he was presented to the rectory of Sutton by Sir R. Burgoin.

Stillingfleet commenced his public life as the advocate of moderate, almost of latitudinarian opinions on ecclesiastical affairs. In the year 1659 he published his first work, which was entitled 'Irenicum, or the Divine Right of particular Forms of Church Government examined.' A second edition appeared in 1662, with an appendix on the Power of Excommunication. This work, which was intended to prove that no particular form of church government is appointed in the New Testament, was thought by the high church party to savour of Presbyterianism; and in deference to them, according to Bishop Burnet, Stillingfleet afterwards retracted it. Stillingfleet himself says that 'there are many things in it which, if he were to write again, he would not say; some which show his youth and want of due consideration; others which he yielded too far, in hopes of gaining the dissenting parties to the Church of England.' (Quotation in Orme's *Life of Baxter*, p. 628; and in Stillingfleet's *Life*, p. 12.)

The work on which his reputation mainly rests is his 'Origines Sacræ, or Rational Account of the Christian Faith as to the Truth and Divine Authority of the Scriptures,' which was published in 1662. He meant to have continued it, but died before he could do so. The additions to the folio edition, published after his death, are of little value. This work is still one of the most valuable defences of the truth of the Scriptures, though it is more adapted to the theologian than to the general reader.

Stillingfleet was a fierce and indefatigable polemic. During the greater part of his life, he had his hands full of controversy, with the Romanists on the one side, and the Nonconformists on the other. In the year 1664 he engaged, at the request of Dr. Henchman, bishop of London, in the defence of the views maintained by Laud in his conference with Fisher the Jesuit. A work having been published on this subject in Paris, entitled 'Labyrinthus Cantuariensis,' with the design of proving the Church of England to be schismatical in her separation from Rome, Stillingfleet defended the Church of England, and retorted upon Rome the charge of schism in 'A rational Account of the Grounds of the Protestant Religion,' which was received with great favour by Protestants.

In 1665 he was presented by the earl of Southampton to the rectory of St. Andrews, Holborn, having been already appointed preacher at the Rolls chapel. This preferment was speedily followed by his appointment as lecturer to the Temple, and also as chaplain in ordinary to Charles II. In 1668 he took the degree of D.D., and was nominated by Charles, in 1670, canon residentiary of St. Paul's, and in 1678 dean of the same cathedral. In the meantime he published his 'Discourse concerning the Idolatry practised in the Church of Rome, and the Hazard of Salvation in its Communion,' 1671; and other tracts against the Roman Catholics, and also against the Socinians, as well as 'A Letter of Resolution to a person unsatisfied about the Truth and Authority of the Scriptures.'

In the year 1680 he plunged into a new controversy, by preaching before the lord mayor a sermon, on *Philip.* iii., 16, which he afterwards published, entitled 'The Mischief of Separation.' This sermon consisted of a violent attack on the Nonconformists, which was little expected from the author of the 'Irenicum.' Mr. Orme justly observes that 'the rector of Sutton, who wrote the "Irenicum" when the Church of England was but a sect among other sects, was a very different person from the dean of St. Paul's exposing the unreasonableness of separation from an apostolic church in all its glory. The one publication breathes a spirit of moderation, and uses the language of entreaty; the other is stern, severe, and uncompromising.' (Orme's *Life of Baxter*, p. 632.) In this discourse Stillingfleet maintains the curious position that 'though the really conscientious Nonconformist is justified in not worshipping after the prescribed forms of the Church of England, or rather, would be criminal if he did so, yet he is not less criminal in setting up a separate assembly.' The sermon was replied to by Owen, Baxter, Howe, and other eminent Nonconformists. Howe directed his attention chiefly to the above position, and added some remarks concerning Stillingfleet himself, giving him such full credit for piety, purity of motive, and general moderation, that the dean confessed 'that Howe had discoursed gravely and piously, more like a gentleman than a divine.' (Rogers's *Life of Howe*, p. 251-266.) Stillingfleet replied to his opponents in a large quarto volume, entitled 'The Unreasonableness of Separation,' 1681, in which he traces the history of Nonconformity; and Baxter rejoined in 'A second true Defence of the mere Nonconformists, against the untrue Accusations, Reasonings, and History of Dr.

Edward Stillingfleet,' 1681, to which the dean made no reply, though several writers carried on his side of the argument. A full account of this controversy is given by Mr. Orme in his 'Lives of Owen and Baxter.'

In 1685 Stillingfleet published his 'Origines Britannicae, or Antiquities of the British Churches,' which gives a full account of the early ecclesiastical history of Britain, from the first introduction of Christianity to the conversion of the Saxons. He rejects many of the traditions respecting the British churches, but is disposed to believe in the alleged visit of Paul to Britain.

When James II. revived the court of ecclesiastical commission, Stillingfleet refused to be a member of it; and after the Revolution he published 'A Discourse concerning the Illegality of the Ecclesiastical Commission, in answer to the Vindication and Defence of it,' 1689. Under Charles and James he was prolocutor of the convocation.

After the Revolution of 1688, Stillingfleet's services to the Protestant cause were rewarded with the bishopric of Worcester, to which he was consecrated in 1689. He immediately addressed himself, with his usual ardour, to correct the irregularities which had arisen in the diocese: he appeared with distinction in the House of Lords; and he still found leisure for polemics. In 'A Vindication of the Trinity, with an Answer to the late Objections against it from Scripture, Antiquity, and Reason,' he made some objections to Locke's definition of substance, and to his theory of ideas in general, which gave rise to a sharp contest between him and Locke.

Stillingfleet died of gout, at Westminster, March 27, 1699. His remains were interred in the cathedral of Worcester, where a monument was erected to him by his son, with a long and highly eulogistic Latin epitaph by Bentley, who was his chaplain.

The character of Bishop Stillingfleet has always commanded the praise even of his opponents, and perhaps many will find a more genuine expression of his worth in Howe's testimony than in Bentley's epitaph. His works prove his industry and learning. Besides the works noticed above, he wrote several theological pamphlets, and a very able defence of the jurisdiction of the bishops as peers in capital cases. His works were printed in 1710, in 6 vols. folio, and a volume of his miscellaneous works was published in 1735 by his son, the Rev. James Stillingfleet, canon of Worcester.

Stillingfleet had collected a splendid library, which Dr. Marsh, archbishop of Armagh, purchased, in order to throw it open to the public in Dublin. The MSS. were bought by the earl of Oxford, and are now in the Bodleian library.

('Life of Dr. Edward Stillingfleet, late Lord Bishop of Worcester,' &c., London, 1710, 1735.)

STILLINGFLEET, BENJAMIN, grandson of Dr. Stillingfleet, bishop of Worcester, was born in the year 1702. His father, originally a physician, and one of the professors at Gresham College, afterwards entered into holy orders, and held the livings of Wood Norton and Swanton, in Norfolk, at the time of his death in 1708. His widow was left with four children in very straitened circumstances, but Benjamin was so fortunate as to obtain a good education at Norwich grammar-school, where he made considerable proficiency. In April, 1720, he entered as subsizar at Trinity college, Cambridge, where he took the degree of B.A. in 1723. Soon afterwards he quitted the University, and became tutor to the son of Mr. Wyndham of Felbrig, in whose family he remained till 1726, when he became a candidate for a vacant fellowship in his own college, but was not successful, owing, as he believed, to the opposition of Dr. Bentley.

After this disappointment he spent many years at Felbrig, and in 1737 accompanied the son of Mr. Wyndham to the Continent. On his return to England the father of his old pupil settled on him an annuity of 100*l*., on which sum and the produce of his literary labours he subsisted for three years. The friendship of Mr. Price, whose acquaintance he had made when at Rome, now enabled him to take up his abode in a small cottage near that gentleman's seat at Foxley, in Hertfordshire. An indifferent state of health first led him to pay attention to natural history, which he afterwards cultivated with great success. In 1759 he published a collection of 'Miscellaneous Tracts on Natural History,' which consisted of translations from the writings of Linnæus and his pupils, calculated to develop the principles of that great botanist. Mr. Stillingfleet's preface to this work did much towards rendering the Linnæan system popular in this country, and constitutes his chief scientific merit.

'A Treatise on the Principles and Power of Harmony,' published in 1771, which is an abridgement of Tartini's 'Trattato di Musica,' was the only other work which appeared during his life; but he left at his death six volumes in manuscript, of a collection towards a General History of Husbandry, of which an analysis is given in his biography by Mr. Coxe. Mr. Stillingfleet died in London, on December 15, 1771, leaving behind him, besides his scientific reputation, the character of an excellent scholar, an elegant poet and musician, and a most amiable and estimable man.

For further information concerning him the reader may consult Mr. Coxe's very interesting work, 'The Literary Life and Select Works of Benjamin Stillingfleet,' London, 1811.

STILLI'NGIA, a genus of plants of the natural family of Euphorbiaceæ, so named in compliment to Dr. Stillingfleet, known as an English botanist. The genus now includes the species of Sapium, and is distinguished by one of its species being the famous tallow-tree of China. The generic character of Stillingia is:—Flowers monœcious. Males aggregate. Calyx cup-shaped, crenulate, or bifid. Stamens two, inserted; filaments united at the base; anthers opening outwards. Female flowers solitary. Calyx tridentate or trifid. Ovary sessile, 3-celled; each cell with a single ovule. Style short, thick. Stigmas three, simple, spreading. Capsule, globose, tricoccous. Cocci single seeded. The species consist of milky trees or shrubs, found in the tropical parts of Asia and America, and likewise in Bourbon and Mauritius. The leaves are alternate, petiolate; petiols biglandular at the apex. Male flowers usually crowded in terminal spikes, supported at the base by a bi-glandular bract. The female flower is commonly below the spike; sometimes subsolitary on another branch.

Stillingia sebifera, or the tallow-tree of China, at one time attracted considerable attention, and was introduced into various European colonies in the East and West Indies. It may be met with in our hothouses. Dr. Roxburgh describes the plant as common in his time about Calcutta, but that it did not yield any useful product, and was therefore only an ornamental tree, being in flower and fruit most parts of the year. It is found in China on the borders of rivulets, and is also cultivated. It grows to the height of a pear-tree, having a trunk and branches like the cherry, and foliage like the black poplar, but which turns red in autumn. It was met with in Chusan by the late expedition, and seeds sent home by Dr. Cantor, which have been sown in the Horticultural Society's Garden at Chiswick. The fruit of this tree furnishes the Chinese with candles, and oil for their lamps. The seed-vessels and seeds are bruised, and then boiled in water. The fatty particles rising to the surface are skimmed off, and on cooling condense into tallow. To give it greater consistence some wax is added, together with linseed-oil, in the proportion of three parts to ten of the tallow. The candles made with it are beautifully white. Sometimes they are coloured red by the addition of vermilion. These candles are sometimes said to be coated with wax procured from another Chinese tree (probably Ligustrum lucidum), which forms an external crust and prevents them running. This tallow is also employed in medicine instead of lard.

STILPO (Στίλπων), a native of Megara, was a philosopher of the Megarian school, who lived about the year before Christ 300. Respecting his life we know very little. He appears to have enjoyed the highest estimation among his countrymen both as a man and a philosopher. Ptolemæus Soter, when he was at Megara, endeavoured to persuade him to come to Egypt, but Stilpo refused, and withdrew to Ægina until Ptolemæus had left Megara. When Demetrius Poliorcetes took Megara, he commanded his soldiers to spare the habitation of the philosopher, who, in his eyes, was the wisest of all the Greeks living. Cicero (*De Fato*, 5), apparently on good authority, states that Stilpo, who was naturally fond of wine and women, exercised such control over his passions, that no one ever saw in him any sign of indulgence in sensual pleasures.

As a philosopher, Stilpo, on the whole, followed the doctrines of the Megarian school, but he went further, and denied the objective reality of the ideas of species and genera. He asserted that the character of a philosopher consisted in perfect freedom from passions; and in this theory he was followed by his disciple Zeno, the founder of the Stoic school of philosophy. Diogenes Laertius, in his account of Stilpo

iii., c. 12), states that he wrote nine dialogues, which he characterises by the epithet 'frigid' (ψυχρός); no part of them is now extant.

(G. L. Spalding, *Vindiciae Philosophorum Megaricorum*, p. 20, &c.; Ritter and Preller, *Hist. Philos.*, p. 181, &c.)

STILT PLOVER. [PLOVERS, vol. xviii., p. 285.]

STILTON. [HUNTINGDONSHIRE.]

STIMULANTS or *Excitants* (in medicine), agents which increase vital action, first in the part to which they are applied, then of the system generally, and perhaps ultimately of some particular organ; and when this organ is a gland or secreting organ, a renewed or augmented secretion is observed. The nervous system seems to be the part which they chiefly influence, and through it the vascular, and in many cases the muscular. This is well seen in the simple effect following the employment of ammonia in a fainting fit, where the application of the vapour of ammonia, or its carbonate (smelling salts), to the nostrils, stimulates the brain, and so restores the heart's action, by which the circulation is resumed, and all parts dependent on it vivified. Aromatic vinegar, electricity, galvanism, and the sudden application of cold, have a like effect.

The agents which constitute this class, though often confounded with others, are perfectly distinct; differing from all by their sensible qualities, their chemical composition, the nature of their physiological effects, and of the therapeutic indications they are calculated to fulfil. They are often confounded with tonics [ANALEPTICS], antispasmodics, and even narcotics, to all of which they have relations of affinity, but are not identical with any. In so far as they both act on the nervous system, they have most affinity with anti-spasmodics [ANTISPASMODICS], but differ from them in as much as stimulants increase the actions which are natural to the different organs of the body; while anti-spasmodics allay or diminish inordinate or abnormal action. Nearly the same may be said of the distinctions between them and narcotics [NARCOTICS], for though the increased action excited by an agent of this class, if extreme or long continued, is followed by a greater or less degree of collapse, still this is very different from that which follows the employment of a narcotic, which is much greater, as well as more speedy. Certain articles, such as opium and alcohol, may be made to act in either way; but while opium is not unfrequently used to stimulate, alcohol is never used medically as a narcotic, though the coma and stupor which ensue from an excessive dose of it, are as profound, and often as fatal, as from an overdose of opium.

Above all, stimulants are most frequently confounded with tonics; but independently of the consideration that stimulants operate directly on the nervous system, while tonics affect the muscular and sanguiferous systems, their operation, as well as the nature of their effects, are entirely different. Stimulants render the movements generally more frequent; tonics render them stronger: stimulants, too freely or too often used, exhaust the excitability; tonics, within a certain limit, maintain it. The action of the one is immediate and transient; that of the other slow, scarcely perceptible, and progressive, but permanent. This is best seen in their effects on the stomach. Tonics render the digestion more perfect; stimulants quicken it: moreover, most tonics must be themselves digested before the system can benefit by them; while stimulants display their effects as soon as they touch the lips or reach the stomach. In many fevers cinchona bark produces no abatement of the symptoms for which it is usually prescribed, as the stomach is too weak to digest it; but capsicum or cayenne pepper given along with it, so rouses the stomach, that the febrifuge power of the bark is then manifested.

Stimulants are of two classes: the former comprise medicinal substances; the latter, warmth, cold, electricity, galvanism, and mental agents, such as music (when lively), joy, hope, &c. Many of the latter class have been already treated of [BATHING; ELECTRICITY; GALVANISM]; of the others, the effects are too familiar to require notice, except to recommend the practice of encouraging the hope of a favourable issue to his complaint in the mind of a patient, in all cases not desperate, as cherishing this feeling greatly increases the chance of recovery. The former class are divided into permanent stimulants and diffusible stimulants, the effect of the permanent being slower but more lasting, that of the others quick but transient. The first are used where a considerable and enduring power is wished to be imparted to the system, as in the convalescence from acute diseases, the other where some great and impending danger is to be obviated, as in cases of fainting, fits, or when sedative poisons are to be antagonised. In these latter instances, ammonia, alcohol in some form, or sulphuric æther, are commonly had recourse to. Permanent stimulants are generally volatile or essential oils, pure, or in the combinations in which they exist in roots, barks, or flowers, and are often highly aromatic: malt liquors may also be classed with permanent stimulants. The precise stage in the progress of fevers and other acute diseases, when antiphlogistic or reducing measures should be abandoned, and stimulants substituted, is the nicest point that a medical attendant is ever called upon to decide; and nothing more clearly distinguishes the judicious practitioner than his correct determination of this point. It may be safely asserted that more cases are lost by a premature use of them, than by delay, as the numerous relapses in fever testify. All persons recovering from severe diseases are almost in the condition of newly born children, in whom the irritability and excitability are very great. These should not be violently acted upon, but on the contrary they should be treated with the utmost gentleness and care. Sleep is a more useful restorative than any other. Stimulants are more necessary during the night than during the day, and as more persons die during that period, the use of stimulants becomes more urgent at that time. But the best and most harmless is a very strong infusion of tea, especially green, given in small quantities, every hour or two, as the danger of the case may point out.

STINGS, in Botany, a kind of hair with which many plants are furnished, which secretes a poisonous fluid, which when introduced under the skin of animals produces inflammation. Many plants are endowed with this kind of protection, the most common example of which is seen in the stinging nettles. In these plants the sting consists of a delicately elongated tube of cellular tissue, which is seated upon a gland formed of the same tissue. The poisonous fluid is secreted in this gland, and when any pressure is made upon the gland, the fluid passes into the tube, just in the same manner as the venom passes up the fang of a serpent's tooth.

In several species of the order Malpighiaceæ the hairs, which are of a peculiar stellate form, possess a poisonous gland, with which they communicate. The genus Loasa and several others are provided with this kind of armature. De Candolle remarks that in all cases where hairs are provided with secretory glands, the fluid secreted is of an acrid nature, and that this fluid is never discharged but when some foreign body presses on the point of the hair.

The poisonous secretion of the glandular hairs, like most other secretions of plants, are more powerfully developed in tropical climates. Leschenault de la Tour gives the following account of the effects of touching the *Urtica crenulata*, which was growing in the Botanic Garden at Calcutta: 'One of the leaves slightly touched the first three fingers of my left hand; at the time I only perceived a slight pricking, to which I paid no attention. This was at seven in the morning. The pain continued to increase: in an hour it became intolerable; it seemed as if some one was rubbing my fingers with a hot iron. Nevertheless there was no remarkable appearance; neither swelling, nor pustule, nor inflammation. The pain rapidly spread along the arm as far as the armpit. I was then seized with frequent sneezing, and with a copious running at the nose, as if I had caught a violent cold in the head. About noon I experienced a painful contraction of the back of the jaws, which made me fear an attack of tetanus. I then went to bed, hoping that repose would alleviate my suffering; but it did not abate; on the contrary it continued nearly the whole of the following night; but I lost the contraction of the jaws about seven in the evening. The next morning the pain began to leave me, and I fell asleep. I continued to suffer for two days; and the pain returned in full force when I put my hand into water. I did not finally lose it for nine days.' (Lindley, *Nat. Syst.*, p. 176.) These effects, though violent, are not so severe as those produced by another nettle, known in the East by the name of Devil's Leaf, which is said sometimes to produce death.

STINT. [TRINGA.]

STIPES, in Botany, a term applied to almost all parts of a plant performing the functions of a stalk, with the exception of the petiole and flower-stalk. It is frequently used to express the whole stem of a plant. The organ which

supports the pistil in some plants, as in *Capparis*, *Lunaria*, and *Colutea*, is called *stipes pistilli* by some writers, and by others Gynophorum and Gynopodium. Stipes is also applied to the setæ of some Mosses, as those of Sphagnum and Andreaceæ. The stalk that supports the pileus or cap in the higher forms of Fungi, as well as the part that supports the organs of reproduction in such Lichens as *Calicium*, *Coniocybe*, and *Bæomyces*, is called stipes. The same term has been applied, though with much less propriety, to the petioles of the leaves of ferns.

STIPPLE. [Engraving.]

STIPULES, in Botany, are those organs which are found at the base and on each side of the axils of the leaves of plants. They are not of constant occurrence, not being found in all plants, but where they occur they frequently characterise a whole family, as in Leguminosæ, Rosaceæ, Malvaceæ, &c. These organs are frequently very like leaves, and present themselves in the various forms in which leaves are found. But they are always to be distinguished from leaves by their position at the base of the leaf-stalk. In many cases they are green, like the leaf; they sometimes have petioles, and are sometimes sessile and cut into teeth, lobes, &c. In the Mimosas the stipules frequently degenerate into hardened spines. In the family of Polygonaceæ they are membranous, and being united together they form a sheath around the stem, which is called an *ochrea*. The stipules in Cucurbitaceæ assume the character of tendrils, and in *Trapa natans* they appear under the form of elongated filamentous bodies.

The size of the stipules varies greatly: sometimes they are very diminutive, and occupy but little space compared with the leaf, as is seen in the little bristle-like stipules of the bird-cherry and the withered scale-like character they present in the buckthorn; whilst in other plants they are very large, as in the hearts-ease, and sometimes they seem to develop at the expense of the leaf, and perform its functions, as in the *Lathyrus aphaca*.

The duration of stipules varies. In some cases they drop off very early, so as sometimes to lead to the supposition that they never existed. This occurs in the Amentaceæ. In many plants they continue on after the fall of the leaf, and this is especially the case in those with spiny stipules; it is also seen in many of the Rubiaceæ, &c.

The character of the stipules is frequently much altered by the adhesions that take place between them. In Magnolia they adhere together by their upper ends, and form a kind of sheath for the protection of the young buds. In some species of Astragalus the stipules of opposite sides meet, and form apparently one stipule with two teeth. This form of stipule is called *synochreate*. In *Melianthus major* the lateral stipules are united through the axil of the leaf, and thus form an intra-axillary stipule and De Candolle supposes that the occurrence of all intra-axillary stipules may be accounted for in this way. In those Geraniaceæ the leaves of which are opposite, the stipules of each side unite, apparently forming but two stipules where there are really four. In Cinchonaceæ, which possess opposite leaves, they adhere sometimes by one edge and sometimes by another; but in most instances the stipules of opposite sides grow together, forming what is called an interpetiolar stipule.

The stipules appear to be modifications of the leaves, but may always be distinguished from these organs by their being placed at the base of the leaf-stalk. Another distinction would also be found in their not possessing buds in their axils. This law however is subject to some exceptions, as stipules are sometimes found with buds in their axils, thus proving their theoretical identity with the leaf.

The function of the stipules generally is not very obvious, but in many cases there can be no doubt that they act as a protection to the young bud, as is seen in Magnolia, and more particularly in the tulip-tree (Liriodendron), where they embrace the young bud in the form of two little valves. In compound leaves the leaflets are often furnished with smaller stipules. These have been called by De Candolle *stipels*. Examples of these may be seen in the species of *Hedysarum*.

STIRIA. [Styria.]

STIRLING, WILLIAM, EARL OF, the son of Alexander Alexander of Menstrie, is generally stated to have been born about the year 1580. The only ground however upon which this opinion rests is the inscription 'ætatis suae 57' on the portrait prefixed to one copy of the edition of his poetical works, published in 1637. His father died in 1594. William succeeded, at his death, to landed property in the counties of Clackmannan and Perth, and accompanied Archibald, seventh earl of Argyle, in his travels on the Continent. Between 1603 and 1614 he published several poems. The tragedy of 'Darius' was printed at Edinburgh in 1603: it was reprinted at London in 1604, with the addition of the tragedy of 'Croesus,' a 'Paraenesis' addressed to Prince Henry, and 'Aurora,' containing the 'first fancies' of the author, and two short pieces, 'Some Verses, written by the author to his majestie, by the author, at the time of his majestie's first entering into England,' and 'Some Verses written shortly thereafter, by reason of an Inundation of Dovan, a water neere unto the author's house, whereupon his majesty was sometimes wont to hawke.' The two tragedies were again printed at London, with the addition of the 'Alexandraean Tragedy,' and 'Julius Cæsar,' in 1607. 'An Elegie on the Death of Prince Henry' was published at Edinburgh in 1612, along with 'Some verses to his Majestie,' and 'A Short View of the State of Man.' The earliest edition of 'Domesday, or the Great Day of the Lordes Judgment,' is that of Edinburgh, 1614. With the exception of two books of an unfinished poem, 'Jonathan,' Alexander published no poetry after 1614, but a pocket edition of the tragedies appeared in 1616, and 'Recreations with the Muses,' a collection of his principal poems, was published in 1637. His poetry is diffuse, deficient in point, and fails to carry the reader along with it; but the versification, though unequal, is often stately and musical, there is a vein of elevated sentiment running through the whole, and the thoughts are those of a man of learning and sound judgment. The 'first fancies' are of course sonnets to his mistress's eyebrow, but the rest are all of a didactic tendency. The opening soliloquy put into the mouth of the ghost of Alexander the Great, in the 'Alexandraean Tragedy,' contains a mixture of lofty ideas, some of them not unworthy of Lucian, which, had the diction been more condensed, must have produced a deep and startling impression. The 'Paraenesis' is curious, inasmuch as the ambitious disposition and habitual train of thought which prompted the colonising speculations of his after-life, may there be traced in their first germ. He was among the first Scotchmen who wrote English: he was Drummond's senior, and was occasionally consulted by him regarding style and rhythm. After all however the poems of Alexander seem to have been less the result of a single-minded love of song, than of a desire to attract notice and open a public career for himself. In this he was successful. Lithgow apostrophised him as 'grave Menstrie, true Castalian fire.' Drayton called him 'my Alexander,' and king James 'his philosophical poet.' His first patron was Prince Henry. On the death of that prince he transferred his services to his brother Charles, whose gentleman-usher he was sworn in 1613. In 1614 the king knighted him, and appointed him master of requests. In 1621, king James granted the territory of Nova Scotia to Sir William Alexander, by a charter dated the 10th of September. The jealousies which disturbed the latter years of James's reign prevented the further progress of Alexander's scheme of colonization till after his death. On the accession of Charles I, Sir William developed his scheme of colonization in a pamphlet entitled 'An Encouragement to Colonies,' published in 1625. An improved edition was published in 1630, under the title of 'The Map and Delineation of New England, together with a Discourse of Plantations and Colonies.' The king was so won by the project, that he made Sir William Alexander lieutenant of New Scotland, and founded, in connection with that colony, the order of knights-baronets in Scotland. The territory was to be divided into parcels not exceeding one hundred and fifty; and Sir William was entitled to dispose of them, with the title of baronet, to the purchasers, for the improvement of the colony. Alexander's idea seems to have been to establish a feudal state, of which he was to be the head, under the *suzeraineté* of the king of England. He is said to have received 200*l.* sterling from each purchaser, and the patents were ratified by parliament, and registered by the lord Lyon king-at-arms. Ultimately however Alexander was induced to cede his claims to the French; but the allegation that he was paid for doing so seems destitute of foundation. The purchasers retained their titles, which were hereditary, and gave them precedence in Scotland of all knights and minor barons. This transaction gave

rise to severe reflections on Alexander. There is every reason however to believe that he was more ambitious of founding a colony than anxious to obtain money, though nowise averse to the latter. He obtained from the king a charter of the lordship of Canada in 1628, and from the council of New England a grant of all that part of New England between the rivers Kennebeck and St. Croix, and of the island of Stirling (now Long Island, in the state of New York), in 1635. He made vigorous efforts to settle this island, and his eldest son contracted the disease which carried him to his grave before his father, by the excessive hardships he underwent in trying to found a settlement on the St. Lawrence. What property Alexander did accumulate seems to have been dissipated in these attempts; for the family estates in Scotland were snatched by his creditors from his third son. It is however pretty clear that he contrived to obtain large grants both of property and honours through the royal favour, and the temper of the times he lived in was not such as to allow such acquisitions to pass without criticism. While busied with the Nova Scotian project, he obtained the privilege of coining for Scotland a sort of base copper-money, called 'turners.' Douglas mentions, in his 'Peerage,' that Alexander having built about this time a large house in the town of Stirling, on which he inscribed his motto, 'Per mare, per terras,' his countrymen travestied it into 'per metre et turners,' in allusion to his making money by poetry and copper-coining. Besides the large grants of land in America, the king granted to him charters of the barony of Menstries, 1628; of the baronies of Largis and Tullibody, 1629; of the barony of Tullicultre, 1634, of the barony of Gartmore, 1636. He was sworn a privy-counsellor, and appointed secretary of state for Scotland in 1626; made keeper of the signet, 1627; a commissioner of Exchequer, 1628; and an extraordinary lord of session in 1631. He was created Viscount Stirling and Lord Alexander of Tullibody, by charter, dated Windsor, 4th September, 1630, and Earl of Stirling, Viscount Canada, and Lord Alexander of Tullibody, by patent, dated at Dalkeith, 14th June, 1633. William earl of Stirling died on the 12th of February, 1640. By his wife Janet, daughter of Sir William Erskine, commendator of the bishopric of Glasgow, he had seven sons and two daughters. The last of his male descendants, Henry, the fifth earl, died without issue in 1739. The earl of Stirling, who held a command in the revolutionary army of America (whose representative still votes under protest at each election of Scottish peers), claimed the title as descendant of Andrew Alexander, younger brother of the great-grandfather of the first earl, the title having been granted to 'heirs-male of the name of Alexander.'

(Kippis's *Biographia Britannica*; Horace Walpole's *Catalogue of Royal and Noble Authors*, Park's edition; Douglas's *Scottish Peerage*, Wood's edition; The Earl of Stirline's *Recreations with the Muses*.)

STIRLING, JAMES, an English mathematician of considerable eminence, but of whom, except the works which he published, scarcely any thing is known. He must have been born near the end of the seventeenth century, and he was a student in the university of Oxford; in 1726 he was elected a fellow of the Royal Society, and his death must have taken place subsequently to the year 1764.

Mr. Stirling's first work is entitled 'Lineæ Tertii Ordinis Newtonianæ, sive,' &c.: this work, which was published at Oxford, in 8vo., in 1717, contains a commentary on Newton's tract on the subject of lines of the third order. In this tract it is shown that all such lines may be expressed by four different equations, of the third degree, between two variable quantities x and y; and that of these equations one, which consists of terms involving the three first powers of x and the two first powers of y, comprehends sixty-five species of hyperbolic curves. Stirling discovered that the same equation contained two additional species, and the Abbé De Gua (*Usage de l'Analyse de Descartes*) subsequently detected in it four others which had been overlooked by Stirling, probably because he directed his researches almost entirely in the steps of his author. The English mathematician has the honour of being the first who observed, if the value of y in the given equation be found in an infinite series of terms containing descending powers of x, that on taking one term only of such series for the value of y, there is obtained an equation of the first degree, which determines the position of a rectilinear asymptote to the curve: that on taking two terms, there is obtained an equation of a curve, which may be considered as an asymptote to the original curve, and which approaches nearer to it than the rectilinear asymptote; and so on. It may be observed however that the division of curve lines into classes and species is arbitrary, Newton, Euler, and Cramer having made the number of curves of the same order very different: it is also now of small importance, since when the equation of any curve is given, the rules of analysis enable the mathematician to determine immediately its tangents, asymptotes, normals, and 'singular' points.

The work which contributed most to Stirling's reputation is his 'Methodus Differentialis, sive Tractatus de Summatione et Interpolatione Serierum Infinitarum:' this work was published in London, in 4to, in 1730; and in the first part of it there are investigated general formulæ, expressing the sums of given series by means of a factor, by which each term in a series being multiplied, the product is equal to the next following term: the factor itself is in the form of a series consisting of terms arranged according to the ascending or descending powers of a variable quantity: and for this variable are to be substituted different numbers increasing from unity. When the given series is not susceptible of having its sum expressed in finite terms, the factor is an infinite series, and then the formula expressing the sum is also an infinite series; but being highly convergent, the summation of a few of its terms gives a very near approximation to the value of the given series. The second part of the work relates to the interpolation of terms between those of any given series: the values of the interpolated terms are found agreeably to the method of Newton, and there are added several theorems for facilitating the processes by which they are obtained. There are also given various formulæ for approximating to the quadrature of curves by the method of equidistant ordinates.

In the 'Philosophical Transactions' for 1735 there is a paper by Stirling 'On the Figure of the Earth and on the Variations of the Force of Gravity at its Surface.' And a second edition of the 'Methodus Differentialis' was published in 1764.

STIRLING. [STIRLINGSHIRE.]

STIRLINGSHIRE, an inland county of Scotland. It is bounded on the north by Perthshire, from which it is in several parts separated by the river Forth; on the north-east by Clackmannanshire and a detached portion of Perthshire, from both which it is separated by the Forth, which here becomes a wide æstuary; on the east and south-east by Linlithgowshire, or West Lothian; on the south by Lanarkshire and a detached portion of Dumbartonshire: and on the south-west and west by the main portion of Dumbartonshire, from which it is separated by Loch Lomond. The form of the county is irregular; the greatest length is from north-west to south-east, from the neighbourhood of Glengyle at the head of Loch Katrine or Cateran, to the shore of the Forth near Grangemouth, 42 miles; the greatest breadth at right angles to the length is from Logie near Stirling, to the neighbourhood of Calder, not far from Glasgow, 25 miles. There are two insulated portions surrounded by Perth and Clackmannan shires, and including the parish of Alva and part of Logie parish. The area of the county is estimated at 502 square miles, or 321,280 acres, of which 13 square miles, or 8320 acres, are in lochs. (Mac Culloch's *Statistical Acct. of the British Empire.*) Dr. Playfair's estimate is 560 square miles. (*Description of Scotland.*) The population of the county at the different enumerations made during the present century was as follows: 1801, 50,825; 1811, 58,174; increase 14 per cent.; 1821, 65,376; increase 12 per cent.; 1831, 72,621; increase 11 per cent.; 1841, 82,179; increase 13 per cent. The number of inhabitants to a square mile, according to the census of 1831 (which we retain to facilitate comparison), and taking Mac Culloch's estimate of the area, was 145; it was at that time the thirteenth county of Scotland for amount of population, exceeding Orkneyshire, but falling short of Dumfriesshire; and the eighth in density of population, exceeding Ayrshire, but falling short of Forfarshire. In area it is the sixteenth county, being larger than Fifeshire but less than Banffshire. Stirling, the chief town, is 31 miles from Edinburgh Castle in a direct line west-north-west, or 35 miles by the road through Linlithgow, Falkirk, and Bannockburn. The county is included between 55° 54′ and 56° 20′ N. lat., and 3° 40′ and 4° 40′ W. long.

Surface; Geology.—The north-western extremity of the county is included in the district of the Highlands, and is occupied by the mountain-range which forms the western ex-

tremity of the Grampians, and separates Loch Lomond from Lochs Chon and Ard, in which the Forth rises. Of this range the principal mountain is Ben Lomond; 'on the north it is precipitous; on the south, setting out from the inn of Rowardennan, on the bank of the lake (Loch Lomond) you ascend easily in three hours, walking over a space of three miles. When you reach its conical summit, overtopping every surrounding eminence, and elevated 3000 feet above the level of the sea, you have on the north an endless succession of mountains like the billows of the stormy ocean; and on the south you have presented before you, as on a map, the riches and beauty of the central district of Scotland from the Western Isles to the Frith of Forth.' (*New Statist. Account of Scotland.*) At the foot of this mountain range, in Loch Lomond, are several islands, part of which are included in Stirlingshire. This range consists of primary rocks, chiefly slates. Roofing-slates frequently occur, and there is some limestone; but neither are available to any extent for economic purposes; the slates because they are too heavy to pay for land carriage, and the limestone because it is too distant from coal.

East of this district the face of the country becomes more level, and is occupied by rocks of the old red sandstone group; but in the central parts of the shire it again rises into hills, which form the group of the Lennox hills, extending from east-north-east to west-south-west from the Forth about Stirling to the Clyde near Dumbarton. They are estimated to attain in their highest part the height of 1500 feet, and present many indications of a volcanic origin. The Campsie Fells, which constitute part of the group, and skirt the valley of the Kelvin, consist chiefly of large tabular masses of trap, the geological position and character of which vary considerably. The other hills of the group, the Gargunnock, Fintry, and Kilsyth hills are chiefly trap or whinstone: the face of them is broken with crags and glens. These trap rocks appear to have penetrated through the old red-sandstone, and through the limestone and the coal formations, which toward the south-east cover the old red-sandstone. That part of the country which skirts the Lennox hills to the south and east, and is drained by the Kelvin, a feeder of the Clyde, and by the Carron and other tributaries of the Forth, belongs to the coal district of Central Scotland, and yields coal, ironstone, freestone, and limestone in considerable quantity. Silver and cobalt were formerly obtained in the detached part of the shire which constitutes the parish of Alva. The carses or dales are generally occupied by the later formations or by alluvium.

Hydrography and Communications.—The county belongs partly to the basin of the Forth and partly to that of the Clyde. The Duchray Water, one of the principal affluents of the Forth, and which some regard as the principal head of that river, takes its rise from several springs on the northern and eastern slopes of Ben Lomond, and forms for five or six miles the boundary of the county. It then enters Perthshire, but again touches the border of the county after its junction with the other principal head of the Forth; and except for a short distance in the parish of Kippen, where its course wholly belongs to Perthshire, and again near Stirling, where it wholly belongs to Stirlingshire, forms the northern boundary of the county till it receives the Avon, which forms the eastern boundary. Its course in the neighbourhood of Stirling is very winding. Its Stirlingshire tributaries are all small; the Bannockburn, the Carron, and the Avon are the principal. Some more important streams, the Teith, the Allan, and the Devon join it on the opposite bank. Up to Stirling bridge the Forth is navigable for small sailing-vessels and steam-boats. At the junction of the Carron with the Forth is the small port of Grangemouth. The Forth abounds in pike, perch, and eels; trout and salmon are not so plentiful as formerly; trout are however abundant in the streams that flow into it.

No part of the Clyde is in this county: but the Endrick and its feeder, the Blane Water, which drain the chief part of the district between the Highlands and the Lennox hills, and the Kelvin, which drains the southern part of the county, are both affluents of the Clyde. The Endrick does not indeed immediately join the Clyde, but falls into Loch Lomond, which communicates with the Clyde by means of the Leven Water. The Endrick abounds in trout. In the parish of Fintry it falls over a rock 90 feet high, presenting, when the waters are swollen by a flood, a magnificent cascade: there is a second smaller fall lower down.

The 'Great Canal,' which connects the Forth and the Clyde, has part of its course in this county. Commencing in the Forth, or rather in the Carron, at Grangemouth, it runs west-south-west into the detached portion of Dumbartonshire: its whole length is 35 miles, or with the branch to Port Dundas near Glasgow 37½: about ten miles of its course belong to Stirlingshire. The canal is on the average 57 feet wide at the top, 27 at the bottom, and nine feet deep: it has 39 locks, and admits vessels of 90 tons burden. The manufactures of Glasgow are conveyed by this canal to the eastern parts of the island; and goods of various kinds conveyed back. This canal was begun in 1768, opened to a certain extent in 1775, and completed in 1790. The Edinburgh and Glasgow Union Canal commences at Port Hopetoun basin, in the neighbourhood of Edinburgh, and joins the Forth and Clyde Canal at Port Downie, near Falkirk, about four miles from Grangemouth; its whole length is 31½ miles, partly in this county. It enters the county by a fine aqueduct bridge over the valley of the Avon, and passes near its junction with the Forth and Clyde Canal through a tunnel nearly 1000 yards long cut in the solid rock. It was begun in 1818 and finished in 1822, and is used for the conveyance of coal, manure, goods, and passengers.

The Edinburgh and Glasgow Railway passes through this county, having its course parallel to that of the Union Canal and of the Forth and Clyde Canal. The Act for this railway was obtained, and the railway itself begun, in 1838. It commences at the Hay-market of Edinburgh, and is carried across the valley of the Avon, where it enters this county by a viaduct of twenty arches, some of them 90 feet high, and terminates in George Square, Glasgow: it passes by a tunnel 845 yards long through a hill near Falkirk. There is to be a short branch to the town of Falkirk.

The Slamannan Railway, which runs from near the termination of the Ballochney Railway in Lanarkshire to the Forth and Clyde Union Canal at Linlithgow, has part of its course in this county: its whole length is about twelve miles and a half; the main line was opened in 1840.

The road from Edinburgh to Stirling, and from thence to Perth and the north of Scotland, enters this county on the east side at Linlithgow bridge, over the Avon, and runs by Falkirk, Bannockburn, and St. Ninian's, to Stirling. At Camelon, just beyond Falkirk, a road branching from this to the left runs by Kilsyth and Kirkintulloch to Glasgow, with a branch from Kirkintulloch to Dumbarton. The road from Stirling to Glasgow falls in with this road between Camelon and Kilsyth; and after coinciding with it for a short distance, turns off to the left, and runs by a more direct line to Glasgow.

Soil, Agriculture, &c.—The hilly district of the centre and the highland tract of the north-west, with the lower lands that lie between them, are in most places bleak and sterile; but the carse, or valley of the Forth, from the neighbourhood of Falkirk to Stirling, consists of low and fertile alluvial lands. The eastern side of the county presents a finely diversified appearance, and the view from Stirling Castle is of almost unequalled beauty.

In the parish of Buchanan, which comprehends nearly the whole of the highland district, with an area of above 76,000 acres, only about 1500 acres are of arable land: this consists of the alluvium on the banks of the Endrick, and on the shore of Loch Lomond. Good crops of oats and a little barley are raised here, and potatoes and turnips are grown. There are above 4000 acres of natural woods or plantations, the latter being chiefly of oak and larch. The woods, both natural and planted, are divided into twenty-four portions, and one is cut every year, so that the whole are cut every twenty-four years: they produce copse-wood, not timber, except that a few trees are left at every cutting for standards: the bark forms an important part of the produce, and a great quantity of small wood is annually consumed in a manufactory of pyroligneous acid and dye-stuffs established in the parish. The products of the manufactory are consumed in the print-works round Glasgow. The greater part of the parish is waste land, used as a sheep-walk or pasture: about 16,000 or 17,000 sheep, chiefly black-faced and of small size, are reared yearly: and about 1300 or 1400 cows or black cattle, and a very few horses.

In proceeding from the highland district towards the south-east the quantity of cultivable land increases. In Drymen, the adjacent parish to Buchanan, of 32,200 acres, about 7000 are cultivated, and are occasionally in tillage: this land is chiefly in the Strath, or valley of the Endrick,

or in the neighbourhood of the Forth. The soil in the Strath of Endrick is a rich brown loam: along the Forth are nearly 3000 acres of deep moss, called 'Flanders Moss,' under which there is a rich clayey soil, capable of producing good crops. The low flat moss lands, of which this is the commencement, and which extend along the Forth all the way to Stirling, distant sixteen miles, are supposed to have originated from the destruction of the forests cut down by the troops of Severus in his war against the Caledonians. Trees of immense size are frequently dug out, lying in various directions, and having the marks of the axe upon them. Improvements in agriculture have been generally introduced into this part of the county: a five-shift rotation of crops is generally adopted in the best lands, and draining has been extensively practised. Two-thirds of the parish consist of moor-lands, partly between the Forth and the Endrick, partly to the south of the Endrick. The small black-faced sheep, improved by the occasional introduction of Linton and Lammermoor rams, are general; but a few Leicesters are kept on the better farms. The Ayrshire breed of cattle is prevalent, though some of the mongrel breed formerly in use are still retained.

In the lower ground which separates the highlands from the Lennox Hills, and in the straths or valleys of the Forth, north of those hills, and of the Kelvin, south of them, the quantity of arable land is greater in proportion. The lower grounds are commonly divided into the carse or valley, and the dryfield or upland slope between the valley and the moorland hills. Oats and hay form the principal crops: barley and potatoes are grown to a considerable extent; and turnips, cabbages, tares, beans, and wheat in a smaller proportion. A six-year shift is the common rotation. Draining and other improvements have greatly extended, and are still extending. Milch-cows are now numerous; the Ayrshire breed is preferred. The butter made and the buttermilk find a ready market in Glasgow. Scarcely any cheese is made except for home use. Many calves are reared, though none are fattened. The hills are occupied as sheep-walks, as in the highland district; and the black-faced sheep from Tweeddale are prevalent. There are some plantations upon and around the Campsie Hills of Scotch fir, larch, spruce, ash, elm, birch, oak, lime, and plane.

The eastern part of the county is the most fertile, and, in an agricultural point of view, the most important. It comprehends the carse or valley of the Forth below Stirling, the soil of which consists principally of a bluish clay mixed with sand. There is comparatively little waste land; the soil is almost wholly occupied in tillage or in plantations: and the greater facility for obtaining manure by means of the navigation of the Forth has tended to the improvement of agriculture. A six-year shift is common; and the produce in wheat, barley, and beans is larger in proportion to other produce than in the more western districts of the county. Gardens and orchards are numerous and productive: the soil is particularly adapted to pear-trees. The horses reared are of superior description.

Rents vary. Arable land in the highland district brings about 25*s.* per acre; but the rent of a farm is commonly calculated by the number of sheep which it will keep, and is about 3*l.* to 3*l.* 10*s.* per score. In Drymen, adjacent to the highland district, the inferior arable land lets at from 10*s.* to 15*s.* per acre; and that of better quality at 2*l.* 10*s.*: the rent of a cow's grazing in the best land is 3*l.* 10*s.*; and of a hill-fed sheep 5*s.* or 6*s.* From the various quality of arable land, great variety of rent is given; perhaps 2*l.* may be taken as the average rent of arable land in the whole shire: in a few instances it rises to 4*l.*, and in some places falls as low as 7*s.* Leases are commonly for nineteen years. Grain rents are common in the lower part of the carse or valley of the Forth, below Stirling. The greatest fairs or markets for cattle in Scotland are held near Falkirk in this county: they are known as 'Falkirk Trysts.'

Wild animals abound in the wastes of the highlands. Ptarmigan and white hares are found on Ben Lomond, and the eagle is occasionally seen there. Grouse are common on the upland moors, and black game and roes are increasing. Pheasants, which were introduced by the late duke of Montrose, have spread through the whole extent of the strath of Endrick. Hares are numerous in the grounds of Buchanan House, where they are strictly preserved. Hares, rabbits, partridges, grouse (black and red), wild-ducks, woodcocks, and pheasants, are common in the Lennox Hills and their neighbourhood, and a few roes are seen: otters, weasels, stoats, polecats, foxes, and squirrels, are numerous; as are the smaller birds of prey. Pike and perch abound in the lochs in Strathblane parish, and in one of them char is found. The streams generally contain trout, and in the lower part of the Endrick the salmon is taken. Badgers and wild-cats, formerly abundant, are now extinct.

Divisions; Towns.—The shire contains twenty entire parishes, and part of five others, viz. Logie, part of which is in Perthshire, and another part in Clackmannanshire; Stirling, which is partly in Clackmannanshire; Lecropt and Kippen, which are partly in Perthshire; and East Kilpatrick, which is partly in Dumbartonshire. It contains the royal burgh of Stirling, the parliamentary burgh and town of Falkirk, the port of Grangemouth, and a number of thriving manufacturing and other villages. Falkirk is described elsewhere. [FALKIRK.]

Stirling, which gives name to the shire, is near the south bank of the Forth. A castle or tower was early erected here, under the protection of which the town grew up; and from its commanding the passage of the Forth, rose early into importance. The name was at first Stryveline or Stryveling; and has been Latinized by Buchanan and others, Starlinœum. It was made a royal burgh; its earliest known charter is dated A.D. 1119. In the twelfth and thirteenth centuries, Stirling Castle was considered to be one of the four principal fortresses of the kingdom; and is one of four which are still upheld by virtue of the articles of the Union. It appears conspicuously in the history of the English wars, and was frequently the residence of the Scottish kings.

The parliamentary burgh of Stirling comprehends the town of Stirling proper, the hamlet of Newhouse, and the village of St. Ninians, which are now united to Stirling by an almost continuous line of buildings. The royalty (or municipal jurisdiction) includes the town and immediate vicinity, but does not extend to Newhouse or St. Ninians, and indeed does not include the castle and government lands, and some lands held in trust for charitable institutions, though they are in the town. On the other hand, some portions of the municipal burgh are north of the Forth, and not within the parliamentary limits. The parish again is not exactly coincident with either the municipal or parliamentary borough. The census of 1831 gave to it 829 houses, inhabited by 1904 families: 3 houses building, and 14 uninhabited; with a population of 8556, of which but a small part was agricultural. The parish of St. Ninians had 1706 houses inhabited by 2055 families, 10 houses building, and 35 uninhabited, with a population of 9552: but from the great extent of this parish, a comparatively small part is comprehended in the parliamentary borough of Stirling. The population of this included part may be estimated at about 2000.

The town of Stirling is irregularly laid out; a winding street or road, not lined with houses throughout, leads to the bridge over the Forth, and by that towards Perth. The Castle-hill, a somewhat long and narrow ridge, is on the north-west side of the town, toward which it rises gently, but presents a steeper slope on the other sides, and is in some parts quite precipitous. The prospect which it commands is very fine. The castle presents a singular assemblage of buildings, some of them antient, but altered and adapted to the purposes of modern warfare. The palace, built by James V., is now converted into a barrack; and the adjacent hall, built by James III. for the meeting of the Scottish parliament, is now a riding-school. Adjacent to this is the chapel royal, built by James III., and rebuilt by James VI. (I. of England), now desecrated and employed as a store-room and armoury. South-west of the castle is the space formerly occupied by the king's park and garden: it is surrounded by an old wall, but is chiefly occupied as pasture or cultivated ground. A series of concentric polygonal mounds marks a spot in the garden, said to have been the scene of some forgotten diversions; a hollow, called 'the valley,' is said to have been appropriated to jousts and tournaments, which the ladies viewed from what is still a craggy pyramidal mound, called 'the ladies' hill.' To the north of the castle are a series of rocky eminences, called the Gowan or Gowlan hills, gradually descending towards the plain: the remotest of these eminences, near the bridge, was the antient 'heading-hill,' or place of execution for state criminals. The castle contains a depôt of arms, and is occupied by a regular garrison.

The more antient streets of the town are narrow, winding, and in many places ill-paved; with decayed houses: but several streets have been much improved in the present century, and are lined with good shops; and the different roads out of the town are lined with neat modern villas, Stirling being a favourite place of retirement for gentry and persons out of business. The town is lighted with gas. The old church, a fine Gothic building, stands near the castle: it has a massy tower of decorated English architecture at its west end. It was originally the conventual church of a Franciscan friary, founded by James IV. in 1494. The nave is low, with round piers and moulded arches pointed, and some good windows of decorated English character. The chancel was built by Cardinal Beaton at a later period than the rest of the building. It is lofty, with fine piers and arches: the east end is an octagon, with a curious stone ceiling. South of the church is Gowane's Hospital, built in 1639; and north of it are the ruins of a curious old house of the earls of Mar, called 'Mar's Work,' deserving of examination. There is another old house, Argyle's Lodgings, of the same period. The old bridge over the Forth is an inconvenient structure of stone, of uncertain date, but certainly as old as the middle of the sixteenth century: a new and more convenient bridge has been built just below it. The wooden bridge, which preceded the old stone bridge, was about half a mile higher up the river: there is a ford at the spot, and the remains of the bridge are still visible at low water. The town-house is an old building with a spire; behind it is the gaol. There are commodious corn and meat markets, and a handsome building, the Athenæum, devoted to literary purposes.

The chief manufactures are of tartan and tartan shawls, carpets, yarns, cotton goods, malt, leather, soap, and candles. There are dye-houses for yarns, home-made cloths, and silks, rope-yards, and breweries. Considerable trade is carried on in corn, wood, coals, bricks, tiles, lime, and wool. About a hundred vessels are said to be engaged in the trade up the Forth to Stirling; and there is constant communication by steam with Newhaven, near Edinburgh, and the intermediate places on the Forth. The market is on Friday, and there is a weekly cattle and horse market between Christmas and Whitsuntide. There are five banking establishments. The circuit court for Stirling, Clackmannan, and Kinross shires, the sheriff's court, and the burgh court are held here.

The burgh council, under the act 3 & 4 William IV., cap. [illegible], consists of a provost, four bailies, a treasurer, and fifteen [illegible] councillors. The corporations are the guildry or merchants, seven incorporated trades, and four other bodies, called 'tolerated communities.' The burgh revenue is above 2000*l.* per annum: the debts amount to about 11,000*l.* Stirling unites with Inverkeithing, Dunfermline, Queensferry, and Culross in returning a member to parliament.

There are two churches of the establishment, formed by dividing the old church, already noticed; each is capable of accommodating nearly 1200 persons; and it has been proposed to erect a third. There are three parish ministers. They hold an evening service in an ex-Cameronian meeting-house. There are two United Secession congregations, one Reformed Presbyterian, one Independent, one Baptist, one Scotch Baptist, one Original Burgher congregation, one Scotch and English Episcopalian, and one Roman Catholic. The Secession kirk had its origin in Stirling, through the deposition, A.D. 1738, of the Rev. Ebenezer Erskine, one of the three ministers of the parish.

There are some important charitable institutions. Gowane's Hospital, for poor members of the guildry and their families, has a clear yearly revenue of 2000*l.*; Spittal's Hospital, for the benefit of the seven incorporated trades or crafts, has a clear yearly revenue of 400*l.*; Allan's Charity, for maintaining, educating, and apprenticing poor boys belonging to the seven trades, of about 300*l.*; and Cunningham's Charity, for similar purposes, for boys belonging to the guildry, has a capital stock of nearly 6000*l.*

There were in 1834 three parochial schools (a grammar-school, an English school, and a writing-school), with five teachers, and from 106 to 109 scholars, chiefly boys; and eighteen other schools (some private; others, partly at least, supported by patronage), with twenty eight teachers, attended by about 455 boys and 376 girls.

St. Ninians consists principally of one long street of old-fashioned houses; some of these are very curious, and have not only the date of erection, but the utensils or other emblems of the trade of the original occupier carved on stones on the front. Several of the houses are whitewashed. There are a parish church and a meeting-house for dissenters of the Relief kirk. The steeple of the former parish church yet remains: the church itself was occupied by the Highlanders in the rebellion of 1745, as a powder-magazine, and was destroyed by an explosion, while the steeple remained uninjured. The inhabitants are engaged in the manufacture of nails and leather; and in the tartan and tartan shawl manufacture, of which Stirling is the centre. The parish of St. Ninians is large, and comprehends, besides the village of St. Ninians, the flourishing village of Bannockburn, comprising, with its colliery, a population of 2400; and several other villages and hamlets. Bannockburn has a considerable share in the tartan and carpet manufactures; and a good deal of business is done in tanning leather.

Grangemouth is in the parish of Falkirk, three miles north-east of the town of Falkirk. It is at the junction of the Forth and Clyde canal with the Carron, near the outfal of the Carron in the Forth. It takes its name from the Grange burn which formerly joined the Carron at this spot, but has lately been made to join the Forth, a mile eastward from the town, in order to convert its former channel into wet docks. The town of Grangemouth was commenced in 1777 by Sir Lawrence Dundas, in the well-founded hope that its connection with the canal would give it some consequence as a port. Having been built on a regular plan, the streets are well laid out and there are some neat good houses; from the flatness of the surrounding country and the adjacent sea-dykes and canal, the place has the appearance of a Dutch village. The town and neighbourhood have been constituted a parish *quoad sacra;* and a new church of Norman architecture has been built by the Earl of Zetland, the proprietor of the town. The Forth and Clyde canal terminates here in a basin and harbour, and two extensive wood-ponds. The basin and harbour afford facilities for large vessels to unload, and for the smaller ones to unload or to wait till they can proceed by the canal, the traffic on which is very great. Since April, 1838, great efforts have been made to improve the port; a wet-dock in the former channel of the Grange burn is in course of construction, with an immense sea lock, second in size to that of Bristol alone; the river Carron has been or is to be deepened; and one of the wood-ponds enlarged and made to communicate with the wet dock by means of a canal. The improvements are expected to be so forward by 1843, as to admit vessels into the wet-dock. There are private wharfs on the Carron.

Grangemouth has a custom-house; Alloa, Stirling, and Kincardine are included in the port. The imports are, grain, both coastwise and from the Baltic; timber from the Baltic, Norway, Canada, and New Brunswick; flax, hemp, tallow, pitch, tar, and manganese ore from the Baltic: cheese, bark, madder, and geneva from Holland and Belgium; and goods of all descriptions from London, Hull, Newcastle, Arbroath, Montrose, Dundee, and Aberdeen. The exports are, coals, pig and wrought iron, glass, bricks, cordage, linen yarn, and cotton and woollen goods. Steam and other vessels are built, and sail-cloth and rope manufactured.

The parochial schools are taught in a neat building in the cottage style, containing two good school-rooms, a library, and dwellings for the teachers, with a large playground. There are a female missionary society, an auxiliary Bible society, and a temperance society.

Kerse House, the seat of the Earl of Zetland, near Grangemouth, is in the Elizabethan style, and is in the midst of a finely wooded park.

Lauriestown is a mile and a half from Falkirk, on the Edinburgh road; the inhabitants are chiefly employed in nail-making, weaving, and agriculture. The village is regularly laid out, with a square in the centre. There are three schools and a Reformed Presbyterian meeting-house. Camelon is about a mile west of Falkirk, on the Glasgow turnpike road. It has a handsome new church and two schools, one built by subscription. The inhabitants are chiefly employed in nail-making. Both Lauriestown and Camelon are in Falkirk parish.

Campsie is a large parish in the southern part of the shire. The population in 1831 was 5109, and is now [illegible] tly 6000; it has increased nearly fourfold since 17[illegible] to the introduction of manufactures. The pri[illegible] is Lennoxtown, which contains nearly half of the population, Torrance has a population of about [illegible] and the[illegible]

are some other villages of tolerable size. There are three places of worship in the parish, namely, a large and handsome new parish church of Gothic architecture, a Relief meeting-house, and a Catholic chapel, all in Lennoxtown, where is also a handsome new school-house. The Catholic congregation consists of Irish, engaged in the cotton printing, the staple branch of industry in the parish. The most extensive print-work is the Lennox mill-field, which lately gave employment to nearly 700 persons of both sexes and of all ages. Kincaid field employed above 370; and Lillyburn field 150, and sometimes more, making a total of at least 1220. The are two bleach-fields which employed about 130 persons: and a work for manufacturing alum, prussiate of potash, prussian blue, &c., which employed 180 persons. There are several coal, ironstone, and lime works.

The state of education in the parish has been very low, but is improving. There are three parochial schools; a large school, not parochial, and an infant-school held in the new schoolhouse at Lennoxtown, built by subscription; and five or six small private schools. The number of children under instruction in day-schools is about 520, besides those in evening-schools and Sunday-schools, and those taught during work-hours in Lennox mill. There are two subscription libraries.

Kilsyth parish adjoins Campsie on the east. The population in 1831 was 4297, and has been nearly stationary since, except that it received a temporary augmentation from the persons employed in the construction of the Edinburgh and Glasgow railway. The village of Kilsyth is at the junction of the roads from Falkirk and Stirling to Glasgow. It is irregularly laid out, and the houses are small and mean-looking; the streets are lighted with gas. The parish church is a modern building of considerable elegance, but far too small for the population; a new church has been built in the village of Banton. There is a meeting-house for the Dissenters of the Relief kirk, and there is a small Methodist chapel, and a Mason lodge occupied as a place of worship by Independents. The inhabitants are chiefly hand-loom weavers employed by the manufacturers of Glasgow; two factories have been commenced lately. There are in the parish a small sickle manufactory, a paper-mill, and a brick and tile work. The Forth and Clyde Canal and the Edinburgh and Glasgow Railway pass near the village. Freestone, limestone, ironstone, and coal are dug in the parish. There is no weekly market, and the two yearly fairs are of no account. Kilsyth has a post office.

Kilsyth was erected, A.D. 1826, into a burgh of barony; it has a baillie and four councillors elected annually, who hold monthly courts for small debts and petty offences; all tenants and proprietors of houses of 5*l.* yearly rental are entitled to vote at the election.

There are three parochial schools, one in the immediate vicinity of the town; and there are two other schools; about 500 children are under daily instruction. There are a savings' bank, three benefit societies, several small libraries, and a temperance society.

Larbert is a parish adjacent to Falkirk parish, on the north-west. It contains the village of Carron, where is the most extensive iron foundry in Europe, about two miles north of Falkirk. There are five blast or smelting furnaces, four cupola furnaces, and twenty air furnaces; besides mills for grinding fire-clay, boring cylinders, grinding and polishing the metal, &c. Water and steam are the moving powers employed. The goods manufactured are machinery, agricultural instruments, and warlike implements, as cannon, carronades (which take their name from this place), mortars, shot, and shells. These works are carried on by a chartered company, the shareholders of which hold and work extensive coal, ironstone, and lime pits; and have about twenty vessels to export their goods to London and elsewhere, and bring back coal and lime. The Carron works employ about 2000 persons.

Denny parish is adjacent to Falkirk parish, on the west. The population in 1831 was 3843, and has since increased to about 4300. It contains four villages, Denny, Hags, Fankerton, and Loanhead, or Louchead. The village of Denny has the parish church with a turreted steeple at the west end 75 feet high, and a United Secession meeting-house. The houses are generally of modern erection, of two stories, with garrets, slated roofs, and sash windows. A neat school-house has been lately built. There is a church belonging to the establishment at Hags (to which a district has been attached as a *quoad sacra* parish), and a United Secession meeting-house at Loanhead. There are in the parish two mills for grinding charcoal for the moulders at the iron-works; two mills for paper and millboards, three mills for the manufacture of tartans, shawls, and linsey-woolsey; a dye-stuff-mill, a saw-mill, and three corn or oatmeal and pot-barley mills; also two distilleries, a brick-work, two calico-print works, a pyroligneous acid manufactory, and a spade manufactory. Most of the mills are on the Carron. Ironstone, freestone, and whinstone are dug, and there is one coal-pit at work. About 1100 persons in the parish and about 200 in adjacent parishes are (or were lately) employed directly or indirectly by the manufactories and mills; 1000 of these are connected with the calico print-works; besides the manufacturing population, about 90 persons are employed in the coal-pit. There are ten schools, one of them parochial, another a dame's school; a parochial library, a religious library, a congregational library at Loanhead, and several benefit, Bible, mutual instruction, and other societies. Denny has a post-office and two yearly fairs. The Forth and Clyde canal, and the Edinburgh and Glasgow railway, pass not far from Denny.

Balfron parish is in the western part of the county; the population in 1831 was 2057, of whom about 1700 were in the village of Balfron, which is in the western part of the parish, 19 miles from Glasgow, and as many from Stirling. The census of 1841 makes the population of the parish 1968. The village is neatly built and clean, and the shops are lighted with gas from the adjacent cotton-works of Ballindalloch, which lately employed about 260 persons, chiefly women and girls. There are many hand-loom weavers: from 300 to 400 looms were lately at work, making light jaconots and lawns. The parish church is a plain building rebuilt in 1832-3; and there are three dissenting places of worship in the parish. There are four schools, one of them parochial, another partly supported by subscription, and having a school-house and master's residence built by subscription, a third in connexion with the cotton-works, by the owners of which it is mainly supported, and the fourth a private school. There is a subscription library.

Kilpatrick parish, sometimes distinguished as East or New Kilpatrick, is at the southern extremity of the county, and is partly in Dumbartonshire: the population in 1831 was 3090; of whom about 1250 were in the manufacturing village of Milngavie. In the parish, and most of them in the village, are a cotton-mill, two bleachfields, three printfields, a distillery, a paper-mill, a snuff-mill, and several corn-mills, giving employment altogether to 900 persons. There is a meeting-house for dissenters of the Relief kirk in the village; the parish church is two miles distant, in Dumbartonshire. There are a parish-school and five private schools, with about 300 scholars; five Sunday-schools, with about 190 scholars; and a respectable subscription library.

The parish of Alva forms a detached part of the county; the village of Alva is on the river Devon, between Stirling and Kinross. The woollen manufacture has long been established in the parish; the earliest article made appears to have been serge; this was succeeded by plaidings and blankets; at present tartan shawls, blankets, and plaidings, and chequered Kerseymeres are the chief articles: about 500 or 600 men, women, and children are employed in this manufacture. The parish school-house, a good building, is in the village; the parish church, on an eminence a little to the east of the village. Besides the parish school, there are a subscription school; and an infant-school and a girls' school, supported by the principal family in the parish.

Fintry is the most central parish in the shire; its population in 1831 was 1051; above 600 of whom are in the village of Fintry, which has arisen from the establishment of a cotton-mill, which contains 20,000 spindles, and employs about 260 persons. There are also a distillery and a small wool-factory. The village consists of a row of houses regularly built, with two stories and a garret, ranged on one side of the road, with their gardens on the other side. There are a parish school and an endowed school, the latter chiefly for the children of those who work in the mill, with a good school-room and house for the teacher: this school has 100 day scholars, and 50 to 60 evening scholars. There are also a Sunday-school and a subscription library. The parish church is a plain neat building, nearly a mile from the village.

In Strathblane parish, on the south-west side of the county, are a calico print-work and two bleachfields, which

give employment to above 200 persons. There are one parochial and two private schools; a young men's society, combining the double object of a religious meeting and a mechanics' institute; a parish library; a savings'-bank; and Bible, missionary, and temperance societies.

Menstrie, with a population of 500, has a woollen-manufactory and a distillery; and the pretty village of Bridge of Allan, with a population of 200, is resorted to for the sake of the adjacent mineral springs of Airthrey. Both are in Logie parish, which is on the north side of the Forth near Stirling.

Divisions for Ecclesiastical and Legal Purposes.—The twenty-six parishes wholly or partly in the shire are arranged as follows:—

Parish.	Presbytery.	Synod.
Baldernock	Dumbarton	Glasgow and Ayr
Balfron	"	"
Buchanan	"	"
Drymen	"	"
Fintry	"	"
Killearn	"	"
Kilpatrick, E. or New	"	"
Strathblane	"	"
Campsie	Glasgow	"
Kilsyth	"	"
Kippen	Dunblane	Perth and Stirling
Lecropt	"	"
Logie	"	"
Airth	Stirling	"
Alva	"	"
Bothkennar	"	"
Denny	"	"
Gargunnock	"	"
Larbert, with Dunipace	"	"
Ninians, St.	"	"
Stirling	"	"
Falkirk	Linlithgow	Lothian and Tweeddale
Muiravonside	"	"
Polmont	"	"
Slamannan	"	"

Larbert and Dunipace are for ecclesiastical purposes united. There are several *quoad sacra* parishes which have been formed by the subdivision of the above. The Seceding churches of the associate synod are chiefly in the presbyteries of Glasgow, and of Stirling and Falkirk; those of the Relief kirk in the presbyteries of Glasgow and St. Ninians; and those of the Reformed Presbyterians in the presbyteries of Edinburgh and Glasgow.

While the Scottish church was episcopal, the parishes in the eastern part of the county were in the diocese of St. Andrews; and those in the western and southern parts in that of Glasgow; Kippen was in the diocese of Dunkeld, and Alva in that of Dunblane. On the erection of the diocese of Edinburgh by Charles I., A.D. 1633, all the parishes in the diocese of St. Andrews, except Logie and Lecropt, were subtracted, and placed under the jurisdiction of the newly created bishop. The Rev. Ebenezer Erskine, one of the leaders of the great secession, and founders of dissent in Scotland, was minister of Stirling, and was deposed from his charge by the General Assembly in 1738. His influence led to the secession of a great number of persons in this shire.

The circuit court of justiciary, and the general quarter-sessions for the county, are held at Stirling. Ordinary and small debt sheriff-courts are held weekly at Stirling and at Falkirk: there is a sheriff-substitute at each place. Sheriffs' small-debt circuit-courts are held quarterly at Drymen, at Lennoxtown of Campsie, and at Balfron. There is a county and burgh prison at Stirling for debtors and criminals, but in the Inspectors of Prisons' Fourth Report (*Parl. Papers* for 1839, vol. xxii.) it is described as being one of the worst in Scotland: the discipline and general management were altogether very bad, and the keeper quite unfit for his place. The average number of criminal prisoners in the year ending 1st October, 1838, was about 26 males and 7 females: of debtors about 3, almost entirely males: the average number for the year ending Michaelmas, 1839, was from 42 to 43 criminals (27 males, and 15 to 16 females), and from 3 to 4 debtors, all males. There is a small burgh gaol at Falkirk, in which there were, on an average of the year 1838-9, 4 criminals, chiefly men. There are small lock-up houses at Alva and Kilsyth. Falkirk and Kilsyth are altogether unfit. The police of the county is altogether insufficient.

The county returns one member to parliament: the number of electors registered in 1835-6 was 2092; viz. 863 sole or joint proprietors, 22 life renters, 1025 leaseholders, or tenants paying a gross sum of 300*l*, 36 husbands voting on their wives' qualification, 35 voters by virtue of office, 7 with joint qualification, and 104 transferred from the old roll of freeholders: in 1839-40 the total number of voters was 2323, viz. 993 proprietors, 127 life renters, 1022 leaseholders, &c., 40 husbands, 38 officers, 5 with joint qualification, and 88 freeholders from the old roll; showing an increase in four years of 231 voters. The detached parish of Alva is, for parliamentary purposes, attached to the county of Clackmannan, but for judicial purposes remains attached to Stirlingshire.

Stirling returns a member in conjunction with Culross, Dunfermline, Inverkeithing, and Queensferry. The number of voters at Stirling was, in 1835-6, 497; in 1839-40, 471, showing a decrease of 26. For the whole district the number was, in 1835-6, 1220; in 1839-40, 1141; showing a decrease of 79. Falkirk returns a member in conjunction with Airdrie, Hamilton, Lanark, and Linlithgow. The number of voters at Falkirk was, in 1835-6, 318; in 1839-40, 387; showing an increase of 69. For the whole district of burghs, the number was, in 1835-6, 1083; in 1839-40, 1369; showing an increase of 286. The writs for the two districts are proclaimed at Stirling and Falkirk respectively.

Education and Crime.—By the Returns made in 1834, and presented to Parliament in 1837 (*Parl. Papers* for that year, vol. xlvii.), the number of parochial schools was thirty-three, with 39 teachers, and a number of scholars varying from 1331 to 1857, nearly two-thirds of whom were boys: the number of other schools was one hundred and twenty-one, with 138 teachers, and a number of scholars varying from 3552 to 5211, about three-fifths of whom were boys; making a total of one hundred and fifty-four schools, with 177 teachers, and from 4883 to 6969 scholars. By making an allowance for defective returns, the estimated number of scholars is supposed to be from 6670 to 8825. The number of children between the ages of five and fifteen who have learned or are now learning to write, as specified in the returns, is 2467, but the estimated number, making due allowance for defective returns, is supposed to be 4959: the number who have learned or are learning to read is by the returns 4223; but after allowing for defective returns, is supposed to be 8489, which is probably not half the whole number of children in the shire. The above returns relate to day-schools alone, not to Sunday-schools.

The state of education in the manufacturing parish of Kilsyth is declared by the inspector of prisons to be unsatisfactory. (*Second Report, Parl. Pap. for* 1837, vol. xxxii.) 'Many parents altogether neglect the instruction of their children. . . . . It is estimated that about two-thirds of the adult population are able to read easily. The people are not however much given to reading.' There is a great deal of drunkenness, and many offences are committed, chiefly assaults and petty thefts, which escape detection and punishment, the police being inefficient. Crime had indeed increased, but not in a greater proportion than population, and the offences were of a less heinous character. (*Report*, as above.)

There appear to be many offences of rather a petty kind in this county, though not many that are very serious. The most common are assaults and thefts. Falkirk, Alva, and Lennoxtown of Campsie, with their respective neighbourhoods, are the places in which offences are most frequent. The offences at Falkirk are chiefly assaults and petty thefts; but the assaults appear to be decreasing: they occur chiefly at Carron (the most notorious place for offences in the east side of the shire), and are usually occasioned by drunkenness. Grangemouth, on the other hand, is one of the most quiet and orderly places in the district. The highland parish of Buchanan, the parishes of Drymen and Killearn in the western part of the shire, Baldernock in the south, and Bothkennar and Slamannan in the east, are stated to be particularly free from crime and disorder.

There is a good deal of crime at Stirling, where there is, for the size of the place, a considerable disorderly population, consisting of prostitutes, thieves, and other loose characters; and there are always a number of vagrants in the town, by whom half the crimes and disturbances are com

mitted. (*Inspectors of Prisons' Second, Third, and Fourth Reports.*)

History, Antiquities, &c.—Stirlingshire was, at the most antient historical period, included in the territory of the Δαμνόνιοι (Damnonii), a nation mentioned by Ptolemy and by Richard of Cirencester, who calls them Damnii. They were subdued by Agricola, A.D. 80, who formed a line of forts through their territory, reaching across the island from the Bodotria Æstuarium, or Frith of Forth, to the Glotta or Clyde: this line of forts, the Roman general Lollius Urbicus, in the reign of Antoninus Pius, about A.D. 140, connected by a continuous rampart of earth or turf. Whether all the forts which may be traced, or which with good reason are supposed to have existed along the line of the rampart, were built by Agricola, or whether the number was increased by Urbicus and his successors, cannot now be determined. The forts, like the connecting rampart, were originally of earth, but appear to have been, at a subsequent period, faced with stone.

The rampart of Urbicus, or, as it is sometimes called from the emperor in whose reign it was constructed, 'the rampart of Antoninus' (Antonini Vallum), commenced on the shore of the Frith of Forth, a little to the east of Borrowstowness in Linlithgowshire, and ran westward through Linlithgow, Stirling, Lanark, and Dumbarton shires, to the Clyde at West or Old Kilpatrick. It consisted of a comparatively slight rampart, with a deep ditch on the north side, and a military road accompanying it on the south side: the remains of it are popularly known as Graham's, Græme's, or Grime's Dyke, a name the origin of which is not ascertained. It entered Stirlingshire in the parish of Polmont, about three miles east of Falkirk, and ran west-south-west through Polmont and Falkirk parishes, into a detached part of Dumbartonshire. In the parish of Polmont all traces of the work have disappeared, but in Falkirk there are some traces of the ditch, which are particularly observable in Callendar park and Lauriestown, just to the east of Falkirk town. The remains of one of the forts may be seen at Castle Cary, six miles west of Falkirk, just where the rampart leaves the shire. It is a square fort, with an area of six acres, the rampart of Urbicus forming its northern side; the military way passed through it from east to west, and another military road entered it from the south. Several antiquities have been dug up in the ruins of a house in the south-east angle of this fort; and from the number of human bones found in the building, and from a great quantity of burnt wheat, it is supposed that the garrison must have been slaughtered, and the place burnt by the natives. It is supposed to have been the Κόρια (Coria) of Ptolemy. Another fort, about three miles and a half to the east of Castle-Cary, is described by Roy (*Military Antiquities of the Romans in Britain*), and Nimmo (*Hist. of Stirlingshire*); but all traces of it have now disappeared, except a slight elevation of the ground marking its site: it was called Rough Castle.

At Camelon near Falkirk, about three-quarters of a mile to the northward of the rampart of Urbicus, were to be seen, some years since, the remains of a Roman station. They were on a Roman road, which led from the rampart to the Forth, which it crossed above Stirling, and thence to the Roman posts in Perthshire. Roy describes the station at Camelon as being, from its extent, and the many vestiges of buildings remaining in it, one of the most considerable which the Romans had in North Britain. It consisted of two parts, the southern part appearing to have been the original station, and the northern part a subsequent addition. All traces of it have now disappeared. The Alauna of Richard of Cirencester is supposed to have been at Kier, in Leckropt parish, between the rivers Teith and Allan, north of the Forth, not far from Stirling: but there do not appear to have been any traces of works observed. The names Alauna and Allan probably embody the same element. The Roman road just mentioned probably ran from Camelon by Alauna or Kier to Lindum (Ardoch), Victoria, and other posts in Perthshire. Some parts of this road may yet be observed near Camelon. It was formerly, and perhaps is still, called Camelon causeway. It is a very carefully-made road, consisting of several layers of stones and earth, filling a trench made for it, and rising above the level of the ground, so as to form a raised causeway, with a small ditch or drain on each side.

A singular building on the banks of the Carron, near where the iron-works are now, supposed to have been a sacellum or chapel, was demolished about a century since. It was a circular stone building, of nearly 20 feet diameter inside, with the walls rising perpendicularly at first, and gradually closing inward so as to form a dome, with a large circular opening at the top 11 feet 8 inches in diameter.

There are some other antiquities referrible perhaps to the Roman period, or to the periods immediately before or after it. There are a few of the stone monuments commonly regarded as Druidical, earthen forts, cairns, and mounds or barrows, in Baldernock, Muiravonside, Gargunnock, Dunipace, Logie, and other parishes. Of the condition of the shire in the ages succeeding the Roman dominion we have no account. It was probably debateable ground, lying near the frontier of four kingdoms, having the Anglo-Saxon kingdom of Northumbria on the south-east, the British kingdom of Strath-Clyde on the south-west and west, the Scottish on the north-west, and the Pictish kingdom on the north and north-east. It is stated by Nimmo, but we believe on very questionable authority, that a severe battle was fought near Stirling, between the Scots, under their king Kenneth II. (Mac Alpin), and the Picts, in the course of that revolution which united the Scottish and Pictish kingdoms under one sceptre. Nimmo (*Hist. of Stirlingshire*) is disposed to trace the name Cambuskenneth, near Stirling, to this battle, and to regard some large stones (supposed by others to be Druidical) near the church of Logie, two miles north of Stirling, as memorials of it.

As the united kingdom of the Scots and Picts was extended by the addition of the territories of the Strath-Clyde and Cumbrian Britons, and of the northern part of the Anglo Saxon kingdom of Northumberland, Stirling became an important town, from its central situation, its strong fortress, and its commanding the passage over the Forth. It early become a royal burgh, sharing the honour with Edinburgh, Berwick, and Roxburgh. Its earliest known charter is of Alexander I., A.D. 1119, but this is simply confirmatory of one conferred previously.

Cambuskenneth abbey, one of the most eminent in Scotland, was founded, A.D. 1147, by David I., king of Scotland, for regular canons of St. Augustin, on a small peninsula on the north side of the Forth, a little below Stirling. Of this edifice some ruined walls and the belfry tower still exist. It was not unfrequently called Striveling or Stirling Abbey, from its neighbourhood to that town.

Other religious houses in the shire were founded by succeeding monarchs.

In the invasion of Edward I. Stirling was abandoned by the Scots and occupied by the English (A.D. 1296). In the rising under Wallace, that chieftain, having made considerable progress in Forfarshire, advanced to Cambuskenneth on the Forth with about 40,000 men, to oppose the English army, which was advancing to Stirling, under the orders of the earl of Warenne and Surrey, guardian of Scotland, and of Hugh Cressingham, an ecclesiastic, whom Edward had made treasurer of Scotland. At the bridge of Stirling, at that time a wooden structure, half a mile above the present 'old' bridge, the English, who numbered above 50,000, were, through the weakness of Surrey and the presumption of Cressingham, utterly routed (11th September, A.D. 1297), and the whole of Scotland was recovered by the blow. Next year (A.D. 1298) Edward in person entered Scotland with an immense army of 80,000 infantry and 7000 cavalry, besides a body of Gascons, and at Falkirk routed Wallace, who could muster only a third part of the enemy's numbers, and whose inferior force was further weakened by the disunion or treachery of its chiefs. The Scots lost 15,000 men; the remains of their army retreated to Stirling, but unable to hold the town, they reduced it to ashes: Wallace resigned his office as guardian of the realm; but Scotland was not immediately subdued. Stirling castle, which was garrisoned by the English, was besieged by the Scots, under the regents, Comyn of Badenoch and John de Soulis, and forced by famine to surrender (A.D. 1299). When in A.D. 1303 Edward overran Scotland, Stirling castle held out against him, and Comyn broke down the bridge, and with all the force he could muster encamped on the ground which Wallace had occupied before his great victory. Edward however passed the river by a ford, and dispersing Comyn's force, quashed for the time all resistance, except in Stirling castle, in which a handful of brave men held out for three months against all the efforts of the king in person, and which was the last fortress that surrendered in Scotland.

In the reign of Robert Bruce, who had recovered Scotland from the English, the great battle of Bannockburn was

fought in this shire (A.D. 1314). Bannock-burn is a small rivulet flowing eastward, south of Stirling, and falling into the Forth below that town, and has given name to a flourishing manufacturing village on or near it. Stirling castle, which appears to have been held by the English ever since its last capture by Edward I. (A.D. 1303), had been besieged by Bruce, and was to surrender if not relieved by midsummer. It was to the relief of this fortress that the English host of 100,000 men were advancing. Bruce, with 40,000 men, encamped between Stirling and Bannockburn, and here awaited the attack, which ended in the utter defeat of the English. Stirling castle surrendered, and Scotland was delivered from impending ruin. This was the third time, in seventeen years, that the fate of that country had depended on a battle fought in this shire; twice, at Stirling and at Bannockburn, it had been delivered by the conflict, and once, at Falkirk, had fallen under the power of its enemies.

In A.D. 1333 Stirling castle, with the rest of Scotland, came into the hands of Edward Baliol and his English allies. It was retaken (A.D. 1341) by the Scots after a long and gallant defence. The garrison were compelled to surrender by famine.

In the reign of James II. Stirling castle was the scene of the assassination of the earl of Douglas (A.D. 1451). The troubles of the reign of James III were brought to a close in this shire by the battle of Sauchie burn, a small rivulet midway between Falkirk and Stirling. (A.D. 1488.) The insurgent lords, with the king's son (afterwards James IV.) at their head, gained the victory over the royal army, and James, thrown from his horse in the flight, was murdered in a cottage to which he had been carried.

Stirling castle was the frequent residence of James V., and from it he frequently issued on those excursions in which he mingled in disguise among his subjects. Sir W. Scott's 'Lady of the Lake' details a supposed adventure of the king in one of these excursions.

James VI. was crowned at Stirling (A.D. 1567) at thirteen months old; and during his childhood, usually resided here with his preceptor Buchanan, who wrote here his 'History of Scotland.' In the troubled period of his minority, while the Scottish parliament were assembled at Stirling (A.D. 1571), the leaders of it were surprised and captured by a party of 400 men, sent from Edinburgh castle by Kirkaldy of Grange, who held out in that fortress for Queen Mary. The surprising party were however defeated, and the prisoners rescued by the earl of Mar, who sallied from the castle. The earl of Lennox, the regent for the king, was mortally wounded in the fray.

The earls of Angus and Mar, with others of those concerned in 'the raid of Ruthven,' took possession of Stirling town and castle (A.D. 1584), but were soon obliged to quit the place and flee into England. Returning next year with a considerable force, they occupied the town, and prepared to invest the castle, where the king (James VI.) was with a very inadequate force. An accommodation took place, and the judicial sentence which had been passed against the fugitive lords was reversed. This transaction is commonly called 'the raid of Stirling.'

Prince Henry, eldest son of James VI., was born at Stirling (A.D. 1594), and his baptism was performed in the castle with great state.

On occasion of the disturbances which arose at Edinburgh on the introduction of the New Liturgy in the reign of Charles I., A.D. 1637, the privy council and the court of session removed to Stirling, to which town none were allowed to repair without a warrant from the privy council; but on the very evening on which proclamation to this effect was made, and another proclamation read appointing the use of the Liturgy, a body of 2000 armed men entered the town, from whence they marched next day to Edinburgh to consult about further proceedings.

The last victory gained by Montrose in his brilliant campaign of 1644-5 was in this county. General Baillie, an officer of experience, who nominally commanded the Covenanters, was compelled by 'the Committee' which had been appointed to direct and control him, to attack Montrose, who, with the Royalist army, was at Kilsyth. Baillie had 6000 infantry and 1000 cavalry, while the Royalists had only 4400 foot and 500 horse; but notwithstanding his superior numbers, he was utterly routed, and nearly all his infantry killed or taken. He fled with such of his cavalry as he could collect to Stirling.

After the failure of the Scots' expedition into England in favour of Charles I., under the duke of Hamilton (A.D. 1648), those who had opposed that expedition rose in arms and a body of Highlanders of the insurgent party, under the marquis of Argyle, was surprised at Stirling and cut in pieces or captured; the rest of the party, under the earls of Eglintoun and Loudon, were posted at Falkirk, and with them an accommodation was entered into, which brought the affair to an amicable issue. The Scotch army retired to Stirling after their defeat by Cromwell at Dunbar, A.D. 1650; and again occupied the town and encamped at Torwood, about six miles south of it, previous to their ill fated march to Worcester (A.D. 1651). Cromwell was encamped at Linlithgow, and vainly attempted to draw the Royalists, who were commanded by Charles II. in person, to a battle. He stormed Callender House, close to Falkirk, in their sight; and having obliged them to retreat from Torwood to Stirling, captured many of their sick and a considerable quantity of military stores. Charles having marched into England and been followed by Cromwell, Monk, whom the latter had left behind him, occupied the town of Stirling, and in a few days forced the castle to surrender. The castle, and the steeple of the church, near which the besiegers had planted their batteries, bear still the marks of the damage sustained during this siege.

In the rebellion of 1715 the Royalists, under the duke of Argyle, marched from Stirling to encounter the rebels under the earl of Mar, at Sheriff Muir near Dunblane. [PERTHSHIRE.] The highland district of Stirlingshire was about this period the resort of the celebrated Rob Roy. In the rebellion of 1745 6 General Cope took post at Stirling previous to his march into the north of Scotland; but the Young Pretender eluded him, crossed the Forth below Stirling, and marched to Edinburgh. On the retreat of the rebels from England they besieged Stirling castle (12th of January, 1746), and General Hawley, at the head of a considerable force, having advanced to relieve it, was defeated by them (17th of January) at Falkirk. The Royalists numbered about 6000 men, the insurgents rather more. The loss of men was not great, but some pieces of cannon were taken, and the whole affair was discreditable both to Hawley and his troops. The siege of Stirling castle was resumed after the engagement, but finally abandoned on the approach of the royal army under the duke of Cumberland; the rebels in their retreat blew up their powder magazine and abandoned their cannon and a number of their sick and wounded.

During the political excitement of the year 1820 some skirmishing took place at Bonny Muir, near Falkirk, between the Radicals and the military, who were sent to repress the disturbances. The Radicals, who were armed, were chiefly from Glasgow.

The principal antiquities, besides Stirling Castle and Cambuskenneth Abbey, are the remains of some old castles and towers There is the keep of an old castle near the Roman fort of Castle Cary, on the line of Urbicus' rampart. Duntreath Castle, in Strathblane parish, is a tolerable extensive ruin. The remains of Colzium Castle crown an eminence near Kilsyth; and the castle of Almond is a massive ruin between Falkirk and Linlithgow. The ruins of Manuel Priory are near the castle of Almond.

(*New Statistical Account of Scotland*; Nimmo's *History of Stirlingshire*; Tytler's *History of Scotland*; *Parliamentary Papers*, &c.)

STIVER. [MONEY.]

STIZOLO'BIUM, a genus of plants which was so named by Persoon, from *stizo*, 'to prick,' and *lobos*, 'a pod,' from the pods of the several species being covered with hispid hairs. The species have now been removed chiefly to Pachyrhizus [DOLICHOS] and to Mucuna: of the latter of these Stizolobium now forms a subgenus. The principle species of Mucuna have already been mentioned under the article COWITCH, or COWAGE, which is no doubt a corruption of the Hindostanee name *kiwach*, which is the *Mucuna prurita* of Hooker, indigenous in various parts of India, but usually confounded with *Mucuna pruriens*, a native of the West India Islands. The Indian M. prurita is distinguished by its smaller leaves, its more obtuse leaflets, the middle one being more truly rhomboidal, its flowers more constantly in threes, and by its legumes being much broader, compressed, and free from any raised line on the back of the valves, whilst in the American M. pruriens the pods are narrower, terete, and keeled on the valves. Another valuable but

little known species is *Mucuna utilis*, the *pois noire* of the islands of Mauritius and Bourbon, and thought to be a native of Arabia. It is universally employed in the above islands for enriching the soil for the cultivation of sugar. The thick covering of herbage with which the soil becomes covered, must be useful in preventing the soil from becoming parched, while the whole crop, being afterwards ploughed in, is found to be eminently useful in enriching the soil. The seed has been introduced into India and is spreading over the country.

STJERNSTOLPE, JONAS MAGNUS, was born December 8, 1777, in the parish of Stenquist, in the province of Södermanland, in Sweden, of respectable parents, but who were so poor that they could afford to give him only the most ordinary education. In all probability therefore his talents would have remained in obscurity, had not his unusual abilities attracted the notice of Baron Fletwood and one of his friends, who put him to school at Strengnäs, where he soon distinguished himself, and whence he was afterwards sent to finish his studies at Upsala. He seems however to have been very scantily provided for, since in order to eke out his means of support he was obliged to give lessons and employ himself in translating novels for booksellers. At length an event occurred in 1802 which he himself has described as a most propitious revolution of fortune, namely, his being taken into the family of M. Beskow, a merchant, as tutor to his two sons, one of whom (Bernhard) has since distinguished himself as a poet, and has edited some of Stjernstolpe's posthumous pieces, with an interesting biography of their author. From this event however no permanent advantage to his circumstances seems to have resulted, for notwithstanding his attachment to his studies, he determined to renounce his prospects in any of the learned professions, and to accept a small appointment in a public office (the Krigs-Expedition), devoting only his leisure time to literary occupations. These consisted at first merely of translations of Muller's 'Siegfried' and other German romances, to the extent of about 30 volumes. It was then that Beskow, wishing to assist him, offered him a situation in his own counting-house, with a salary more than double of what he then had; but he rejected the well-meant proposal, saying, that he preferred drinking water and writing verses to drinking wine and casting up accounts. Though he himself might not consider the labour of translating drudgery, that kind of it in which he first engaged was certainly unworthy of his talents. Therefore although it is to be regretted that he did not undertake some original work of similar extent, it was not without advantage to the literature of his own country that he afterwards transplanted into it some of the productions of such writers as Cervantes, Wieland, and Voltaire. Besides 'Don Quixote,' 'Oberon,' and some of the tales of Voltaire, his translations of this class include those of Pope's 'Rape of the Lock,' and Blumauer's 'Æneis' (which latter poem he completed by adding the three last books, and which is considered to be in many respects even superior to the original); not to mention a number of minor pieces, both from antient and modern poets. Among his original productions, which are comparatively few, the principal are, 'Lunkentus,' a dramatic popular tradition; the 'Argonauts;' and his comic tales in verse.

Notwithstanding his decided taste for works of fancy and humour, satire and wit, his reading extended to others of a very different class, to mathematics and the physical sciences, geology and astronomy, to which last study he was greatly attached. According to his biographer Beskow, the same remarkable sort of contrast displayed itself in his conversation, for he would pass alternately from the gayest and liveliest topics to the most serious, from the most playful to the most profound. His conversational powers were, in fact, of the highest order: it was there that the originality of his mind fully displayed itself, for he possessed such extraordinary *improvisatore* talents, that he would delight his auditors almost an entire evening by a continual flow of wit and eloquence, which carried away both himself and his hearers. These captivating qualities and the amiableness of his personal character, his frankness and his disinterestedness, caused his society to be greatly sought after by all who were distinguished in literature and art; whence it was said of him that he was not only known to all Sweden, but intimate with one half of it. He constantly refused however to become a member of any literary society for which institutions he entertained no great respect. His epistolary correspondence was very extensive, and was marked by the same qualities as his conversation, though hitherto but a few specimens of it have been published by his biographer. He had commenced a translation of Ariosto, but did not live to make any great progress with it, being carried off by a paralytic attack on the 17th of September, 1831. (Beskow, *Minnesteckning*.)

STOAT. [WEASELS.]

STOBAE'US, JOANNES, a native of Stobi in Macedonia, whence he derives his name Stobaeus, lived either at the end of the fifth or in the sixth century of our æra. Respecting his life no particulars are known. We possess through him a number of extracts from antient Greek writers. He collected them in the course of his extensive reading from more than five hundred authors, both in prose and in verse, and put them together, and arranged them according to subjects for the use and instruction of his son Septimius. We are thus indebted to Stobaeus not only for an immense number of fragments of well known antient writers, but some authors would be altogether unknown to us if Stobaeus had not preserved their names, together with some of their sentiments. The words of Greek poets are of course quoted verbatim, but in regard to prose writers he followed two different methods; sometimes he quotes the author's own words, and gives us real extracts, and sometimes he gives a mere summary or epitome of what his author contained. He himself called this anthology from Greek literature, Ἀνθολόγιον ἐκλογῶν, ἀποφθεγμάτων, ὑποθηκῶν, and divided it into four books. But the work has come down to us in a somewhat different form. In our MSS. it is divided into three books, which form two separate works. The first and second books are usually called Ἐκλογαὶ φυσικαί, διαλεκτικαί, καὶ ἠθικαί, and the third Ἀνθολόγιον, or Sermones. It has therefore been supposed that one book of Stobaeus is lost, but it is more probable that the 'Sermones' contain the third and fourth books in one, according to the original division. It is true that the third book at present consists of 127 or 128 chapters, while in the time of Photius the two last books together only contained 100 chapters. This difference in number however may be accounted for by supposing that some of the larger chapters were divided by copyists into two or more smaller ones.

The editio princeps of the 'Eclogae' is that by W. Canter, Antwerp, 1575, fol., with a Latin translation. It was reprinted, together with the 'Sermones' (the first edition of which was edited by Trincavelli, at Venice, 1536, in 4to.), at Geneva, 1609, in fol. C. Gesner published three editions of the 'Sermones.' under the title 'J. Stobaei Sententiæ,' Tigur., 1543; Basil., 1549, and Tigur., 1559, with many arbitrary alterations. The best modern edition of the 'Eclogæ' is that by A. H. L. Heeren, with notes and a Latin translation, Göttingen, 1792-1801, 2 vols. 8vo.; and the best edition of the 'Sermones' is that by T. Gaisford, Oxford, 1822, 4 vols. 8vo., reprinted at Leipzig, 1823 and 1824, in 4 vols. 8vo. A complete edition of both works of Stobaeus has been published by Tauchnitz, at Leipzig, 1838, in 3 vols. 16mo. (Schöll, *Geschichte der Griech. Lit.*, iii., p. 395-414.)

STOCK, the English name for the genus of plants named by Brown *Matthiola*. [MATHIOLA.] Many of the species of this genus are great favourites in gardens, on account of their handsome flowers and fragrant smell. In order to raise the more valued kinds, as the double-stock gilliflower, the Brompton and queen's stocks, the seed should be saved from plants growing among double flowers, as it has been proved that such seed produce more plants with double flowers than the seed obtained from plants bearing double flowers. The seed should be sown in May, and when the young plants have attained a height of two or three inches, they should be thinned out till they are about nine inches asunder. The plants that are taken out may be planted in the flower-border, at about six inches distance from each other. If the following winter should be severe, they should be covered over with mats. In the following spring they will produce their flowers. The annual or ten-week stock (*Matthiola annua*) may be sown three or four times in the season: in February, March, April, and May; those that are sown in the last month will blossom till Christmas. All the annual sorts may be treated in this way. The double varieties of the shrubby kind may be propagated by cuttings, under a hand-glass, and placed in a shady place. A soil that is light and mixed with sand is the best adapted for them. The stock will not bear transplanting at a late period of its growth, as its fusiform root is not

supplied with lateral radicles, and the spongioles at the end of the root are almost sure to be destroyed when this operation is deferred beyond a few weeks.

STOCKBRIDGE. [HAMPSHIRE.]

STO'CKHOLM, the capital of Sweden, is situated in 59° 20′ N. lat. and 18° E. long., on the channel by which the lake Mälarn discharges its waters into the Baltic. Following the numerous windings of this channel, the open sea is reached at a distance of 36 miles from the town, but in a straight line the distance does not exceed 24 miles. The channel varies in width between less than a mile and five miles, and is interspersed with numerous rocky islands.

The city of Stockholm is built partly on the continent and partly on nine islands formed by the above-mentioned channel: the islands are called *holmen*. In the middle of the channel are the islands of Stockholmen, also called Staden, because the town was originally first built on it, and Riddar Holmen (the island of the knights). South of them is the large island of Söder Malm, at the western extremity of which are Lang Holmen and Räkning Holmen. North of the channel a large portion of the town is built on the continent, and called North Malm. With this part is united the island of Kongs Holmen (King's Island), which lies west of it, and those of Blasii Holm, Skepps Holmen (Island of Vessels), and Kastell Holmen, which are east of North Malm.

The Staden, or Stockholm, occupies the centre of the town, and contains several fine public and private buildings. The royal palace, an edifice of great architectural merit, stands on an eminence, and is surrounded by a large garden. Besides the apartments in which the royal family reside, it contains a library, collections of paintings, coins, and antiquities. Before the extensive court-yard of the palace, and near the banks of the channel, is the colossal statue of Gustavus III, of bronze: and in its vicinity, along the eastern shore of the island, is the proper harbour of the town, in which the largest vessels find excellent anchorage. Along it there are large storehouses for foreign goods. Farther to the west is the cathedral, or St. Nicolai Church, also called 'storkyrka,' or head church, in which the kings of Sweden are now crowned: and at some distance from it, on the Riddarhustorg (or Square of the Hall of the Knights), is the statue of Gustavus Vasa, of bronze. From the square a stone bridge leads to the Riddarholmen, which is much smaller than Stockholmen, but which contains several large public buildings, among which are the old palace and the old church of Riddarholmen, in which the kings and distinguished persons born in Sweden are buried, and about five thousand flags are hung up, the trophies of the Swedes in their numerous wars. The legislative body also holds its meetings here.

Söder Malm, or the southern division of Stockholm, is built on the island of the same name, which is about three miles long and nearly two miles across in the widest part: it is joined to Stockholmen by a long bridge of boats, and provided with a large lock on account of the great rapidity with which Lake Mälarn sometimes discharges its waters. The surface of the island is rocky and very broken; and though there are also many fine buildings near the channel, the interior of this section of the town is mostly composed of small wooden houses situated between rocks and swamps, and of gardens and corn-fields. In the Söder Malm is the great depôt of iron, whence it is shipped to all quarters of the globe. The most remarkable of the buildings are the town-hall, the Danviken or Great Hospital, and the Maria Magdalene and the St. Catharine Church. The island of Lang Holmen, which is farther west, and is united to the Söder Malm by a bridge, contains the houses of correction; and on Räkning Holmen, which likewise is joined to Söder Malm by a bridge, there is a park.

The Norr Malm, or northern division of the town, is on a gentle slope, which gradually rises about 200 feet above the sea-level. It is much better built than the Söder Malm, and has several fine squares and streets, among which King's Street is distinguished by many good buildings. A well-built bridge connects it with Stockholmen. On the finest of the squares, called that of Gustavus Adolphus, is the bronze equestrian statue of that great king. One of the sides of the square is occupied by the opera-house, a fine large edifice. Not far from the square is the king's garden (Kungs Tregorden), a fine piece of ground, planted with trees and used as a public promenade, in which a statue of Charles XIII. has been erected; and near it is the play-house. Among the churches of this part of Stockholm, that of Adolphus Frederick is distinguished by its beauty. At the northern extremity of Norr Malm is the observatory, which is well provided with astronomical instruments and a library; and somewhat farther is the botanical garden. The island of Kungsholmen, which lies west of Norr Malm, is joined to it by two bridges. It is not much built on, but contains the great iron-foundry established by an Englishman, Mr. Owen; a large hospital, the Bible printing-office, and the royal cannon-foundry of Marieberg. Contiguous to the Norr Malm on the east is Ladugords Gärdet, on which formerly were some royal farms, a part of which however has been built upon; whilst another part has been converted into a royal park, called Humblegord (hop-garden), to which the public has access. The island of Blasii Holmen, which has been converted into a peninsula by filling up the narrow channel which divided it from the continent, is north-east of Stockholmen and south-east of Norr Malm, of which it now constitutes a portion. It contains some fine buildings. Contiguous to it, and only separated by a narrow channel, over which there is a bridge, is the small island of Kyrkholmen, from which a long wooden bridge leads to Skeppsholmen, where the flotilla of the skära is stationed. Another wooden bridge leads to Kastellholmen, a very elevated island, planted with fine trees: a castle is built here for the defence of the entrance of the harbour.

There is probably no capital in Europe, except perhaps Constantinople, which can be compared with Stockholm as to the beauty of its environs. The numerous channels between the islands—in some places contracted to the narrowness of a river, and at a short distance expanding to the dimensions of a lake, enclosed by a rocky bank, changing continually in elevation and form, and overgrown with beech, birch, and pines, and at several places cut by narrow valleys, partly cultivated and partly covered with meadows—present an infinite variety. Country-houses are dispersed over the hills surrounding the town; but the place which is most resorted to for pleasure is the zoological garden, which lies eastward of the town, and is separated from the Skeppsholmen and Kastellholmen by a narrow arm of the sea. It is a peninsula two miles long and about one mile wide, and its surface is diversified by groves of birch, beech, and pines, by steep rocks and numerous depressions, frequently covered with a fine turf. Within the zoological garden is the royal country-seat of Johansdal, formerly called Rosendal, which is surrounded by a large park. Other royal country-houses are north of Norr Malm, as Ulriksdal, Haga, and Carlsberg: the last is now a military academy. But the most distinguished of the royal country-houses lie to the west of the town, on islands in the lake of Mälern; they are Gripsholm, Drottningholm, and Swartsjö. Drottningholm is an edifice distinguished by great beauty, and contains a fine collection of pictures and coins. Swartsjö is surrounded by an extensive park.

Stockholm is the seat of the government, and generally also the place where the legislative bodies meet. It contains consequently the offices of all the branches of administration and the superior courts of justice. There are several scientific and literary societies, among which the Royal Society of Sciences has greatly contributed to the advancement of natural philosophy, chemistry, and natural history. There is also a Royal Academy of literature, history, and antiquities; the Swedish Academy, whose object is to promote the cultivation of the native language; an academy of military sciences, an academy of liberal arts, a musical academy, and an academy of agriculture. The charitable institutions are very numerous, and in this respect Stockholm is superior to any other city in Europe of equal size. The institutions for education are also numerous. Besides a well-conducted grammar-school, there are some schools for the middling classes, and 14 elementary schools, mostly conducted on the plan of Bell and Lancaster. There is also a school for grown-up persons whose education has been neglected, and who wish to improve their knowledge.

The population of Stockholm consisted, according to the census of 1825, of 79,473 individuals; in 1833, according to Forsell's account, of 81,000; and in 1839, of 83,585 persons, according to the same authority. The number of families in 1825 was 14,436, of which 1314 were rather wealthy, 8777 in comfortable circumstances, and 4345 poor. The number of persons employed by government and their families, the military included, did not exceed 8453; and

the remainder consisted of merchants, tradesmen, mechanics, and seamen, with their families, and the persons attached to their business.

Stockholm is the most industrious and commercial town of Sweden. There are manufactures of cloth, cotton, calico, silk, ribands, sugar, tobacco, leather, cast-iron, and soap. But no branch of manufacturing industry is carried to such an extent, either in Stockholm or in any other place in Sweden, as to supply the demand, and large quantities of foreign manufactures, and especially English, are annually imported.

The commerce of Stockholm is more important. Nearly the whole of the superfluous produce of the countries north and west of Stockholm is brought here, to be exported to foreign countries. It is mostly shipped in Swedish vessels, of which in 1827 Stockholm possessed 146, with nearly 27,900 tons burden, and crews amounting to 1507 persons. The most important article of export is iron: according to an average of ten years (1821-1830), it amounted annually to 31,993 tons. The second article is timber, boards, &c.; and the third is tar and pitch. Minor articles are copper, cobalt, ready-built vessels, linseed-oil and oil-cakes, tobacco, steel, bricks, and a few manufactured articles. The most active commerce is carried on with England, the United States of North America, Denmark, France, Prussia, Portugal, the Netherlands, and Italy. The most important articles of import are sugar, coffee, wine and brandy, rum, woollen manufactured goods, cotton, silk, linens, china and crockery, hemp, cotton, cheese, potash, hides and skins, tallow and candles, train-oil, dyeing-woods, raisins, almonds, pepper, cinnamon and cassia, tea, butter, and wool.

(Forsell's *Statistik von Schweden*; Forsell's *Anteckningar öfver Sverige*, Stockh., 1839; and Schubert's *Reise durch Schweden, Norwegen, Lapland*, &c.)

STOCKING WEAVING. [WEAVING.]

STOCKPORT, an important manufacturing town and parliamentary and municipal borough, on the river Mersey, partly in the parish of Manchester, in the hundred of Salford, in the county of Lancaster, but chiefly in the hundred of Macclesfield, in the county of Chester, 180 miles north-west from the General Post-office, London, by the coach (formerly mail) road, through Barnet, St. Albans, Northampton, Leicester, Derby, Ashbourn, Leek, and Macclesfield, and about seven miles south-east from Manchester.

Stockport, antiently called Stokeporte and Stocport, was made a free borough by Robert de Stokeporte, with the permission of Edward I. as earl of Chester: the same Robert had the grant of a market and an annual fair. There was an antient castle at Stokeport, of which not a vestige now remains. The town was garrisoned by the Parliamentarians in the great civil war, and was taken, A.D. 1644, by the Royalists, under Prince Rupert, who had previously repulsed the garrison, 3000 in number, when they marched out to attack him: the Parliamentarians subsequently recovered the place. Stockport-bridge was blown up in 1745, to prevent the retreat of the rebels after their advance to Derby; and they were in consequence obliged to wade through the river.

The parish of Stockport, which is wholly in Cheshire, comprehends an area of 24,810 acres, with a population of 66,610: it is divided into fourteen chapelries or townships, of which the township of Stockport (which coincided with the antient borough) had an area of 1710 acres, with a population of 25,469; but the town having extended beyond the township, and across the Mersey, into Lancashire, the parliamentary boundaries were, by the Boundary Act, made to comprehend, in addition, the most populous parts of the township of Heaton Norris (in Manchester parish), part of the township of Brinnington, in Stockport parish, and the hamlets of Brinksway and Edgeley, in the townships of Cheadle Bulkeley and Cheadle Moseley, in Cheadle parish; the whole having a population of about 43,000. The town stands at the junction of the rivers Tame and Mersey, and consists of a number of streets irregularly laid out, with a large open market-place in the centre. It is well paved under the provisions of the general Highway Act, and is lighted with gas under a local act. The principal part of the town is built on a steep and irregular hill of soft red sandstone, rising in some parts precipitously from the south bank of the Mersey. The market-place and the parish church are on a tolerably extensive level on the summit of the hill; the streets leading to them are steep and narrow. There are four bridges in or near the town, over the Mersey, and one over the Tame. The 'old bridge' over the Mersey, near the market-place, is of one arch, built high above the river to avoid the inconvenience caused by the sudden and violent swelling of the stream, and having its abutments built on the solid rock, which here lines the banks of the river. Below the 'old bridge' is another bridge, of eleven arches, crossing not only the river, but its valley, at an elevation of 40 feet above the water. The arch over the river is of 90 feet span; most of the dry arches are on the Cheshire side. This bridge was built that the Manchester and Buxton turnpike-road might avoid the ascent and descent caused by the uneven site of the town.

The parish church is, for the most part, modern, having been rebuilt early in the present century, in the perpendicular style of architecture. It has a tower with pinnacles and pierced battlements, a nave with side aisles, and a chancel. The chancel is the sole remaining part of the former building, but it has been much altered. It had a fine east window of decorated English character, but much decayed, the old church having been built of soft red-sandstone: there were also some fine stone stalls in the south wall of the chancel. There are three other places of worship of the establishment in the borough, viz. St. Thomas's church, built A.D. 1825, a handsome building of Grecian architecture, with a tower surmounted by a cupola; St. Peter's chapel, a neat brick building, erected about the middle of the last century; and a district chapel of modern erection in Heaton Norris. Besides these, there are a number of dissenting meeting-houses of different persuasions. There were, in 1834, three for Independents, three for Methodists, and one each for Baptists, Unitarians, Roman Catholics, and Quakers. There are some very large Sunday school-rooms, built by subscription at a cost of above 6500*l.*; a grammar-school, lately rebuilt by the Goldsmiths' Company of London; a very large national school, an infirmary, which is a very ornamental building, and a small theatre.

Stockport is one of the principal seats of the cotton manufacture. Pigott's 'Directory' for 1834 enumerates nearly one hundred and twenty firms in Stockport and Heaton Norris engaged in different branches of this manufacture; there are also three cotton-printing establishments, two bleaching establishments, and several dye-houses. To the cotton manufacture, which is the staple of the town, may be added the manufacture of silk goods, thread, hats, brushes, spindles, and shuttles. About 4500 men were, in 1831, engaged in manufactures in and round the town. There are several breweries, a distillery, several iron and brass foundries in the town, and a great number of bricks are made in the neighbourhood. There are three banking establishments. A branch canal communicates with the Manchester and Ashton canal, and the town is on the line of the Manchester and Birmingham Railway, which has been opened between Manchester and Stockport. The market is on Friday, and is the most important in Cheshire for corn, oatmeal, and cheese. There are four yearly fairs, chiefly for cattle.

Stockport was formerly incorporated, but the corporation, previously to the late Municipal Reform Act, had gone to decay; a mayor was chosen at the court leet and baron of the manor; but his office was merely nominal, the jurisdiction of the town being in the hands of the county magistrates. By the Reform Act Stockport was made a parliamentary borough to return two members; the boundaries of the borough have been already described. The number of voters, in 1835-6, was 1137; in 1839-40, 1279. By the Municipal Reform Act the parliamentary boundaries were adopted for municipal purposes, the borough was divided into seven wards, a number which the revising barristers reduced to six; the town council consists of fourteen aldermen and forty-two councillors, and the town has a commission of the peace.

Stockport has an auxiliary Bible society, a news-room, and a subscription library. Two newspapers, 'The Stockport Advertiser' and 'The Stockport Chronicle,' are published in the town.

The living of Stockport is a rectory, in the rural deanery of Macclesfield, and in the archdeaconry and diocese of Chester, of the clear yearly value of 1882*l.*, with a glebe-house. The chapelries of St. Thomas and St. Peter are curacies, of the clear yearly value of 110*l.* and 220*l.* respectively; Heaton Norris is a chapelry, in the parish and rural deanery of Manchester and in the same archdeaconry and diocese as

Stockport; its clear yearly value is 116*l.* The townships of Stockport, Brinnington, Heaton Norris, Cheadle Bulkeley, and Cheadle Moseley, which are wholly or partly in the borough, had the following number of schools in 1833:—

	Day Schools.	Scholars.	Sunday Schools.	Scholars.
Stockport .	50	1962	8	7259
Brinnington .	2	114	..	..
Heaton Norris	9	481	4	1141
Cheadle Bulkeley	9	336	3	653
Cheadle Moseley	4	163	1	345
	74	3056	16	9398.

One of the day-schools at Stockport is an endowed grammar-school, under the patronage of the Goldsmiths' Company of London. It had, in 1833, 150 boys; another was a national school, with 235 boys and 170 girls. One of the Sunday-schools, 'the Stockport Sunday-school,' was not exclusively connected with any denomination. The Bible was used as the school-book, and the children were taken alternately to church and to dissenting places of worship. This school, with four branches, had, in 1833, 5244 scholars, about half of each sex. It was supported by subscription, and was under the management of a committee elected from among the subscribers of a guinea and upwards, and of visitors chosen from among the persons actively engaged in the school. There were two libraries, a teachers' library of 850 volumes, and a scholars' library of 1700. There were connected with the school a religious tract society which circulated yearly 30,000 tracts, and a Bible association which distributed yearly about 400 copies of the Scriptures. There were no paid officers connected with the institution.

STOCKS, in Horticulture, are young trees which are designed for the reception of the grafts or buds from other trees. The process by which a part of one tree is transferred to another is called grafting or budding [GRAFTING], and the object attained by it in gardening is the securing the continuance and multiplication of an individual plant that may possess peculiarities deemed worthy of preservation. It is by this process that the great number of varieties of cultivated fruits are preserved with remarkable integrity, and by which a constant improvement may be ensured.

In the process of grafting much depends on the stocks which are employed, and it is by ascertaining the best modes of growing stocks, and the relation that exists between the various kinds of stocks and the grafts and buds that are placed upon them, that we are to look for the improvement of the various kinds of garden fruit.

Stocks are for practical purposes divided into three kinds. Crab stocks, free stocks, and dwarf stocks. Crab stocks are those which are grown from the seeds of wild and ungrafted trees, as the cherry, plum, apple, &c. These stocks are commonly used where a large and hardy growth is desirable. In the selection of wild stocks, those which grow cleanest, and are freest from irregularities of the stem and defects in the bark, should be chosen. Free stocks are those which are raised from the seeds or layers of fruit and orchard trees which have been grafted. These stocks are found desirable when the object of grafting is to obtain choice varieties of apples, peaches, nectarines, apricots, or plums. Dwarf stocks are those which are raised from low-growing shrubby trees. They are used in the grafting of low-standards for small gardens, also for wall-trees, and espaliers.

Stocks are raised in nurseries from seeds, suckers, layers, and cuttings. When raised from seeds, they should be sown in the autumn, in beds of common light earth: all lateral branches should be cut off as they grow up; and, according to circumstances, they will be fit for grafting in one, two, or three years. Stocks may be used when they have attained the size of a goose-quill, up to that of a man's finger. When stocks are wanted expeditiously, they may be produced from suckers taken up and planted in the autumn, when they will be ready for use the following July or August. They are not often raised from layers and cuttings.

In the selection of stocks, not only is care required that they be of the same kind as the graft or scion, but that there is a proper relation between the rapidity of their growth according to the objects wished to be attained. When the growth of the scion is more rapid than that of the stock, it will sometimes die. This is the case with peach-trees budded on plum-stocks and pears on the hawthorn. At the same time, when trees are naturally too luxuriant in leaves and branches, they may be dwarfed in their growth and made fruitful by placing a scion from them on a stock that grows slower than themselves. In this way apples may be dwarfed by being grown on paradise, pear, or quince stocks. Of this fact Knight gives the following explanation:—'The disposition in young trees to produce and nourish blossoms, buds, and fruits, is increased by this apparent obstruction of the descending sap; and the fruit of such young trees ripens, I think, somewhat earlier than upon other young trees of the same age which grow upon stocks of their own species; but the growth and vigour of the tree, and its power to nourish a succession of heavy crops, are diminished, apparently by the stagnation, in the branches and stock, of a portion of that sap which, in a tree growing upon its own stem or a stock of its own species, would descend to nourish and promote the extension of the roots. The practice therefore of grafting the pear-tree on the quince-stock, and the peach and apricot on the plum, where extensive growth and durability are required, is wrong; but it is eligible wherever it is wished to diminish the vigour and growth of the tree, and where its durability is not thought important.' (*Hort. Trans.*, ii.)

It is frequently desirable to select those stocks which are hardier than the scion, for the purpose of ensuring the growth of the latter. Not that the stock has any power of communicating hardiness to the scion; but those stocks that are accustomed to colder latitudes will supply a sufficient quantity of sap, and be able to resist the influence of a decrease of bottom heat.

M. Dubreuille of Rouen has lately pointed out the fact that the kind of soil in which a stock grows has something to do with its being adapted for the growth of certain scions Thus he found that in the chalky gardens about that city, neither the plum nor the wild cherry would do as stocks for stone-fruit, nor the doucin or quince stock for pears and apples. The crab was found best for the apple, the wild pear for the cultivated pear, the almond for the plum, and the mahaleb for the cherry.

The following table, from Dr. Lindley's 'Theory of Horticulture,' p. 24, gives a comparative view of the stocks that were found best suited for the scions of the apple, pear, plum, and cherry, in three different soils:—

Scions.	*Stocks.* Loamy soil.	Chalk soil.	Light soil.
Apple .	Doucin.	Crab.	Doucin.
Pear .	Quince.	Wild pear.	Quince.
Plum .	Plum.	Almond.	Almond.
Cherry .	Wild cherry.	Mahaleb.	Wild cherry.

It has long been known that many scions did better on another species of stock than on their own, but it was not known that soil could have any influence on this; and hence is opened a field of interesting inquiry for the vegetable physiologist and horticulturist.

STOCKS, a term applied to the various 'Funds' which constitute the national debt. The number of distinct accounts of stock on which dividends were paid in 1839 was as follows:—

Dividends not exceeding		Dividends not exceeding	
£ 5 . .	85,069	£ 500 . .	2827
10 . .	45,147	1000 . .	1367
50 . .	98,946	2000 . .	266
100 . .	26,205		
200 . .	14,816	Exceeding	
300 . .	4,495	2000 . .	192

Each proprietor of stock may transfer his interest to others by sale. When the transfer is effected by a broker he must be authorised by a power of attorney from his principal, the stamp-duty on which is 21*s.* 6*d.*; and the document may be so drawn as to empower him both to buy and sell stock and to receive the dividends for the person by whom he is commissioned. Few persons buy or sell stock except through the medium of a broker, but the general practice is to receive their dividends themselves. The purchaser acquires the dividend due upon the stock for the current half-year, and thus at one point there will be a sum of 29*s.* 4*d.* due on three-per-cent. stock, and a fortnight afterwards only 1*s.* 8*d.* On the bargain being completed, the parties repair to the Bank or South Sea House (according to the stock), where the actual transfer is effected. 'For this purpose the seller makes out a note in writing, which contains the name and designation of the seller and purchaser, and the sum and description of the stock to be transferred. He delivers this to the proper

clerk, and then fills up a receipt, a printed form of which, with blanks, is obtained at the office. The clerk, in the mean time, examines the seller's accounts: and if he find him possessed of the stock proposed to be sold, he makes out the transfer. This is signed in the books by the seller, who delivers the receipt to the clerk; and upon the purchaser's signing his acceptance in the book, the clerk signs the receipt as witness. It is then delivered to the purchaser upon payment of the money, and thus the business is completed.' (Dr. Hamilton, *History of the National Debt.*)

Bargains in stock are transacted in the Stock Exchange, in Capel-court, Bartholomew-lane. Brokers and jobbers who are not members assemble in the open court in front of the building. All the more respectable brokers are members of the Stock Exchange, into which association they are elected annually by ballot; but many of the jobbers are said to be persons of wealth. The governing body consists of a committee of twenty-four, also elected by ballot. The established rate of brokerage is one-eighth per cent. (or 2*s.* 6*d.* in the 100*l.*) upon the amount of stock transferred. There is no stamp-duty or tax of any kind upon transfers of Government Stock; but the transfer of Bank Stock under 25*l.* costs 9*s.*, above that amount, 12*s.*; of South Sea Stock under 100*l.*, 10*s.*, above it, 12*s.*; and of India Stock, of any amount, 1*l.* 12*s.*

The dividends on all descriptions of stock are due half-yearly, either on the 5th of January and 5th of July, or on the 5th of April and 10th of October, and are paid about a week afterwards; and for about six weeks previously, the books at the Transfer Office being closed, transfers cannot be regularly made. The transfers on each stock are effected at other times only on certain days in the week, which may be ascertained by a reference to any Almanac.

The bargains for *time* form a very important portion of the business of the Stock Exchange. They are bargains to deliver stock on a certain day at a certain price, the seller of course believing that the price will fall, and the buyer that it will rise. When the period for completing the bargain has arrived, a settlement is usually effected without any payment of stock, the losing party simply paying the difference. 'These bargains are usually made for certain days fixed by a committee of the Stock Exchange, called *settling days*, of which there are about eight in the year, viz. one in each of the months of January, February, April, May, July, August, October, and November; and they are always on Tuesday, Wednesday, Thursday, or Friday, being the days on which the commissioners for the reduction of the national debt make purchases. The settling days in January and July are always the first days of the opening of the Bank books for public transfer; and these days are notified at the Bank, when the books are shut to prepare for the dividend. The price at which stock is sold to be transferred on the next settling day is called the price *on account.* Sometimes, instead of closing the account on the settling day, the stock is carried on to a future day on such terms as the parties agree on. This is called a *continuation.*' (Dr. Hamilton.) Time bargains cannot be enforced in a court of law, and the parties are held to them only by a sense of honour and self-interest, and the fear of exclusion from the Stock Exchange, which ruins their credit. A defaulter, in the language of the Stock Exchange, is termed a 'lame duck,' and his name is posted for a certain time in the great room. The sellers of time bargains are also technically called 'bears,' and the buyers 'bulls;' the interest of the former being to beat down prices, and of the latter to raise them.

Stock of a high denomination may usually be bought cheaper than that of which the nominal interest is lower; and it is therefore the most advantageous for temporary investment. There is always a probability that the stock bearing the highest rate of interest will be reduced by the government when a favourable occasion presents itself; but the price of any one stock may be taken pretty nearly as an indication of the prices of the rest. For example, when 100*l.* in three per cent. stock costs 90*l.*, the par would be 105*l.* in a three and a half per cent. stock. When the Government reduces the interest on a particular stock, it is guaranteed against further reduction for a specified period; and this period having expired in regard to the New Three and a half per Cent. Stock, its relative value, compared with the Three per Cent. Stock, is as 90 to 99, there being always a probability that the interest on the former may be reduced. The fluctuation in the price of stocks generally may be traced to an almost infinite variety of causes—to the abundance or scarcity of money, and the opportunities of employing it to advantage in mercantile speculations; to the rumours of a new loan, or of the imposition of a fresh tax, or even the repeal of a tax; to rumours of war; and to innumerable other circumstances relating to the trade, finance, and other domestic affairs of the country. In 1797 the Three per Cents. were reduced to the lowest point which they have ever reached (47⅞) by the success of the French armies, combined with adverse circumstances at home.

The following is a brief notice of each description of stock at present existing, which are bought and sold on the Stock Exchange, with the amount of each on the 5th of January, 1841:—

1. South Sea Stock, divided into the Company's Stock, or trading capital, amounting to 3,662,784*l.*; Old South Sea Annuities, 3,497,870*l.*; New South Sea Annuities, 2,460,830*l.*; and South Sea Annuities of 1751, 523,100*l.*, all of which have been created out of the capital of the famous South Sea Company by successive Parliamentary arrangements. The interest paid by the State upon the whole amount of this stock is now 3 per cent., although the dividend received by the proprietors of the 3,662,784*l.* of Company's trading stock is 3½ per cent. The additional half per cent. is obtained from certain fines and from the allowances made by Government for the management of this portion of the public debt.

2. Debts due to the Bank of England, amounting to 14,686,800*l.*, advanced at different times by the Bank to the public; the Bank receives interest on the amount at the rate of 3 per cent.

3. Bank Annuities, created in 1726, amounting to 825,251*l.* This stock was originally 1,000,000*l.*, which was raised in 1726, by lottery, to pay off arrears that had accumulated on the Civil List, and for which Exchequer bills had been previously issued: it bears interest at 3 per cent.

4. Consolidated Annuities, commonly called Three per cent. Consols. The amount of this stock, in January, 1841, was 362,542,977*l.* It was originally formed by the union of several funds which had before been kept separate, in the year 1751, at which period it was little more than 9,000,000*l.*

5. Three per Cent. Reduced Annuities, amounting to 125,861,030*l.* This stock consists of various sums originally borrowed at a higher rate of interest, but on which the interest has been afterwards reduced at different times.

6. Annuities at 3½ per Cent., 1818, amounting to 10,159,721*l.* Formed in 1818, partly by the funding of Exchequer bills, and partly by the conversion of certain 3 per cent. consolidated and 3 per cent. reduced annuities.

7. Reduced 3½ per Cent. Annuities, amounting to 66,259,849*l.* Formed in 1824, by the conversion of a former stock called the Old Four per Cents.

8. New 3½ per Cent. Annuities, amounting to 145,225,865*l.* Formed in 1830 out of the former stock called the New Four per Cents.

9. New 5 per Cent. Annuities, amounting to 428,076*l.* Formed in 1830, by the same arrangement out of which the New 3½ per Cent. Annuities then arose.

The total amount of the Irish Stocks, on the 5th of January, 1841, was 33,909,266*l.*

Besides these several stocks, there are—

1. The Long Annuities, occasioning an annual charge of 1,294,140*l.* These have been granted at different times, chiefly as premiums or douceurs to the subscribers to loans, and all expire on the 5th of January, 1860.

2. The Annuities per 4 Geo. IV., ch. 22, commonly called The Dead Weight Annuity. This is an annuity of 585,740*l.* paid every year by the public to the Bank of England, and to be so paid till the year 1867, in consideration of advances to the amount of 13,089,419*l.* made by that establishment. [NATIONAL DEBT.]

3. Life Annuities per 48 Geo. III., ch. 142, 10 Geo. IV., ch. 24, and 3 Will. IV., ch. 14, occasioning a charge of 857,856*l.* These are annuities upon the lives of individuals, which the Commissioners for the redemption of the National Debt were originally empowered to grant by an Act passed in 1808, in exchange for so much stock in interminable annuities as was calculated to be of equivalent value, according to a scale varying with the fluctuations in the prices of stocks. In 1829, however, Mr. Finlaison, the Government actuary, discovered that the tables which had been all along used in these calculations were erroneous,

when the Act upon which the annuities are now granted was passed.

4. Annuities for terms of years, under the above Acts, of which the present charge is 1,314,927*l.* These annuities are granted for various terms of ten years and upwards.

5. There are certain Tontines, and other Life Annuities granted by various Acts, of which those forming part of the English debt occasioned, in January, 1841, a charge of 9,969*l.*, and those forming part of the Irish debt, a charge of 34,230*l.*

The two following descriptions of stock, in addition to the above, are constantly operated upon by the sale and purchase of shares at the Stock Exchange.

1. Bank Stock, being the trading capital of the Bank of England, or that upon which interest is paid to the proprietors, amounting formerly to 14,553,000*l.*, but since the last renewal of the charter, in 1833, to only 10,914,250*l.* The interest is 8 per cent.

2. East India Stock, or the capital belonging to the East India Company, amounting to 6,000,000*l.* Ever since 1793 the interest upon this stock has been 10½ per cent.

Besides these English funds, shares in many descriptions of foreign stocks, which have been created by loans raised in this country, are constantly for sale in the money-market, as are also shares in railway, canal, mining, and numerous other similar speculations.

STOCKS, a wooden machine formerly much used for the punishment of disorderly persons by securing their legs. The time when they were first used in England does not appear; but in the second Statute of Labourers, 25 Edw. III., A.D. 1350, in the octave of the Purification, it is enacted that refractory artificers shall be put in the stocks by the lords, stewards, bailiffs, or constables of the towns where their offence has been committed, by three days; or sent to the next gaol, there to justify themselves; and that stocks be made in every town for such occasion between that time and the feast of Pentecost. (*Rot. Parl.*, ii., 234.) In 1376 the commons prayed the king for their establishment in every village. (*Ibid.*, 341.)

In 'King Lear,' act ii., sc. 2, Shakspere has introduced the stocks upon the stage. Farmer, commenting upon the passage (see Malone's *Shaksp.*, edit. 1821, vol. x., p. 99), says, 'It should be remembered, that formerly in great houses, as still in some colleges, there were moveable stocks for the correction of the servants.' The last pair of stocks seen in London remained till within these very few years in Portugal-street, Lincoln's-Inn-Fields. A whipping-post usually adjoined the stocks.

STOCKTON, distinguished as STOCKTON-UPON-TEES, a town in the south-west division of Stockton ward, in the county of Durham, 340½ miles from the General-Post-office, London, by railway through Birmingham, Warrington, Manchester, Normanton, York, and Darlington; or 212½ miles by the coach (formerly mail) road through Barnet, Biggleswade, Norman Cross, Stamford, Grantham, Newark, East Retford, Doncaster, Abberford, Boroughbridge, Thirsk, and Yarm.

Stockton was at an early period the residence of the bishops of Durham, who had a hall here, which afterwards was called the castle, though in fact only a strong moated manor-house, where Bishop Morton took refuge (A.D. 1640) when the army of Charles I. was defeated by the Scots in the skirmish at Newburn. In 1645 the town was occupied by the Scotch army; and in 1647 the castle was ordered by parliament to be dismantled, and was entirely demolished in 1652. It commanded the passage of the river. The traces of the moat and embankment still mark the site.

The town is situated on the left bank of the Tees, which approaches the town in a northward direction, and then makes a sudden bend toward the east. The town is laid out with considerable regularity; the principal street is broad, and extends nearly a mile in a straight line from south to north: other streets either branch from this at right angles or run parallel to it. The wharf is on the bank of the river, just above the bend, and runs parallel to the High Street. Near the south end of the High Street the London and Darlington roads, united, enter it from the west; and quite at its southern extremity a road from it bends first to the south-east, then to the east, and crosses the Tees into Yorkshire by a stone bridge of five arches, erected (A.D. 1764-1771) in the place of the previously-existing ferry. The streets are well paved, and lighted with gas, under a local act. The houses are for the most part of brick; the few that are built of stone are from the materials of the castle. The church is on the east side of the High Street, and at the eastern end of the church is a green, now inclosed and formed into a square. Altogether Stockton is one of the handsomest and cleanest towns in the north of England. The church is a spacious and convenient brick building, erected early in the last century, with a tower at the west end 80 feet high. There are places of worship for Independents, Baptists, Unitarians, Quakers, Wesleyan and Primitive Methodists, and Roman Catholics. The town-hall, in the middle of the High Street, is a respectable quadrangular building, surmounted by a clock tower and spire. There are a custom-house, a news-room, assembly-rooms, billiard-rooms, and a small theatre. There is a race-course on the opposite side of the Tees.

The parish of Stockton comprehends an area of 4190 acres: the population, in 1831, was 7991: it is divided into the three townships of Stockton, Hartburn, and Preston: the township of Stockton, which contains the town, has an area of 2610 acres, with a population, in 1831, of 7763. The principal manufacture is that of linen and sail-cloth, which latter employs 400 hands: some ship-building, rope and sail making, and yarn and worsted spinning are carried on: there are also iron and brass foundries, breweries, and several corn mills. Stockton is a port: the harbour is formed by the river Tees, the navigation of which has been improved by a cut just below the town, whereby a considerable bend is avoided. The chief imports are timber, deals, masts, spars, staves, iron, hemp, flax, tallow, oak-bark, linseed, clover-seed, hides, &c., chiefly from the Baltic, Holland, Hamburg, and British America; and groceries, wine, spirits, and colonial produce, brought coastwise. The exports to foreign parts are chiefly lead, and that in small quantities: the exports coastwise to London, Leith, Hull, Sunderland, &c, are chiefly of flour, butter, cheese, bacon, oak timber, linen, linen and worsted yarn, lead, and especially coal, the export of which has much increased. Communication is maintained with London and with Newcastle-upon-Tyne by steam-packets; and with Darlington, York, Manchester, Birmingham, and London by railway. The Stockton and Darlington Railway, which forms the first part of this line of communication, has one terminus on the quay, in the very heart of the town, and extends by Yarm and Darlington to Witton Colliery, near Bishop Auckland. A branch to Middlesbrough, a rising port in Yorkshire, lower down on the Tees, parts from the main line just to the south of the town of Stockton, and is carried over the Tees by a suspension bridge (just above the stone bridge at Stockton), 240 feet long within the piers, and 30 feet above low-water mark. This railway was commenced under an act obtained in 1821, and was opened in 1825. Its whole length with the branches is 54 miles: it is the first railway on which locomotive engines were employed. A branch of the Clarence Railway (which extends from the Stockton and Darlington Railway, between Darlington and Bishop Auckland, to the mouth of the Tees, on the Durham side), has its terminus on the east side of the town. There are two weekly markets (Wednesday and Saturday) and two yearly fairs, besides a cattle-fair or great market on the last Wednesday of every month. There are four banking establishments at Stockton. There are extensive coal-works and some brick-yards near the town, and a salmon and other fishery in the Tees.

Stockton has a savings'-bank, a mechanics' institution, a dispensary, and almshouses.

Stockton is a borough by prescription; it has no charter, nor had the corporate officers any jurisdiction. Petty-sessions were held weekly by the county magistrates for Stockton ward. The borough comprehended only a small portion of the town; but a considerable extension of its limits has been recommended. By the Municipal Corporations' Reform Act the borough was divided into two wards, and has six aldermen and eighteen councillors. The borough has now a commission of the peace. Stockton is a polling-station for the southern division of the county of Durham.

The living of Stockton is a vicarage, in the archdeaconry and diocese of Durham, of the clear yearly value of 247*l.*, with a glebe-house.

The township had, in 1833, twenty-one day-schools, with 902 children of both sexes; and five Sunday-schools, with 611 children. Of the day-schools, one, with 203 boys and 70 girls, was supported by endowment; and another, with

40 girls, partly by endowment and partly by annual subscription. The other townships of the parish have no school. A later account enumerates a grammar-school, a national school, a blue-coat charity-school, and seventeen private schools.

STOFFLER, JOHN, a celebrated German astronomer, who was born December 10, 1452, at Justingen in Swabia. He was appointed professor of mathematics in the University of Tübingen (in Wirtemberg), where, besides pure mathematics, he taught astronomy and geography, and he appears to have been successful in gaining the esteem of his numerous pupils, among whom are said to have been Melanchthon and Sebastian Münster. In the year 1530 he made a journey to Vienna, in order to be present at the installation of a professor of mathematics in the University of that city; and, according to Melchior Adam, he died of a contagious malady at Blaubeuren, February 16, in the following year, being 79 years of age. His funeral was celebrated with great magnificence, and his tomb was adorned with his effigy.

According to the practice of astronomers in that age, Stoffler spent much of his time in the computation of ephemerides, and he appears to have been first brought into notice by continuing the series which Müller (Regiomontanus) had commenced. He constructed an astrolabe, which was intended to be used as an instrument for making celestial observations, and on the plane of which were projected the circles of the sphere: an account of the astrolabe was given by him in a tract which was published at Tübingen in 1513; and in the same tract there is given an account of an instrument for determining the hour of the day by an observed altitude of the sun. Stoffler was addicted to the study of astrology; and in the ephemeris for the year 1524 he announced that, in consequence of a conjunction of the superior planets in the month of February, there would happen a deluge which would be fatal to the human race. Many persons had faith in the prediction, and took measures to save themselves, and it is remarkable that the fact of the prediction being found to be erroneous, neither disposed the author to renounce the study of astrology nor diminished the sale of his ephemerides. He published these works in a regular series from the year 1500 to about 1531.

Stoffler employed himself on the subject of reforming the Julian Calendar, and it is stated that he was the first who proposed to rectify the error of that calendar by the omission of ten days in one year, in order to make the succeeding days of the year correspond, as at first, to the place of the sun in the ecliptic. It is said also that Stoffler offered his project to the Lateran council, and that it was not accepted.

Besides the ephemerides, and the above-mentioned tract on the use of the astrolabe, Stoffler published astronomical tables (Tübingen, 1500); a tract on the calendar (Oppenheim, 1518); and a commentary on the Sphere of Proclus (Tübingen, 1531)

STOICS. [ZENO.]

STOKE, distinguished as STOKE-UPON-TRENT, one of the new parliamentary boroughs created by the Reform Act, in the northern division of Pyrehill hundred, in the county of Stafford. Stoke, which gives name to the borough, and Burslem, one of the principal towns in it, are each 152 miles north-west from the General Post-office, London, by Barnet, St. Albans, Daventry, Coventry, Coleshill, Lichfield, Stone, and Newcastle-under-Lyne; or 162 miles by the Birmingham and Grand Junction railways to Stafford, and from thence by Sandon and Newcastle. Hanley, the largest town in the district, is about a mile farther.

This borough has this peculiarity, that instead of comprehending one principal town and its suburbs, it consists of a considerable district, extending 7½ miles in length from north-north-west to south-south-east, and above 3 miles in breadth at the widest part. It includes the township or liberty of Tunstall Court in Wolstanton parish; the township of Burslem with the vill of Rushton Grange and the hamlet of Sneyd, in Burslem parish; and the chapelries of Hanley and Lane-End, and the townships of Shelton, Penkhull, Boothen, Fenton-Vivian, Fenton-Culvert, and Longton, in Stoke parish. In this district, the chief seat of the earthenware manufacture of England, familiarly designated 'the Potteries,' are the market-towns of Burslem, Hanley, Lane-End, Stoke, and Tunstall Court. The district is of no historical interest; its importance has arisen from the manufacture of which it is the seat. [EARTHENWARE.] Burslem is described elsewhere. [BURSLEM.]

Hanley is near the centre of the district, about a mile from Stoke. It is united with Shelton into one market-town, the largest in the district. It stands on the south-western slope of a gently rising eminence. Most of the streets have been laid out within the present century; they are wide and have a brick pavement for foot passengers on each side, and are lighted with gas. There are some spacious and elegant houses, but the generality are smaller and of tolerably uniform height, viz. of two stories. The market-place is large and surrounded by spacious shops; in it is a pump or fountain, in the form of a Doric pillar of cast-iron, surmounted by a lamp. The market-hall is convenient; in one corner is the watch-house, in another corner is a two-celled prison or lock-up-house. The church, or rather chapel, at Hanley is a commodious brick building with a tower 100 feet high. A new church has been built in Shelton. There is a neat building for the national school, and a handsome one for a British school. There are several places of worship for different classes of Dissenters; that for the Methodist New Connection has a large Sunday-school room attached to it, capable of containing 1000 children.

The population of Hanley chapelry and Shelton township, in 1831, was 16,388: 1444 men were returned as engaged in manufactures; they were nearly all engaged in the earthenware manufacture, in which they were assisted by their families. There is one banking establishment, and there is a large paper-mill of modern erection. Etruria, a long street of about one hundred and twenty houses, with a Wesleyan Methodist chapel and a large British school, an extensive earthenware manufactory (Wedgwood's) and a mansion (Etruria Hall), erected by Josiah Wedgwood, the great improver of the earthenware manufacture of the district [EARTHENWARE, vol. ix., p. 243] is in Shelton township, and its population is included above. These are well supplied markets on Wednesday and Saturday, the latter being the principal; the tolls, which a few years since produced 700*l.* per annum, are appropriated to the improvement of the town.

Lane-End is at the south-south-east extremity of the district, about three miles from Stoke. It was formerly remarkable for the irregularity with which it was laid out, but the more modern parts are regularly laid out, and built with tolerable uniformity. There are two places of worship of the establishment; one built, or rather rebuilt, in 1795, the other in 1834; several Dissenting or Methodist meeting-houses, and a Catholic chapel; an English free-school, and a large national school. Lane-End has two market-places: one, with regular shambles and stalls, is used for the weekly market; the other, with a spacious market-hall, commonly used for public meetings, is appropriated for the yearly fairs. The market tolls are devoted to the improvement of the town. The population of the chapelry of Lane-End, and of the township of Longton, into which the town extends, was, in 1831, 9608; of whom 981 men (besides their families or assistants) were employed in manufactures, almost entirely of earthenware. There is an iron-work for smelting the ironstone found in the neighbourhood. There are two banking establishments. The market is on Saturday. There are several yearly fairs.

Stoke has a number of modern houses, regularly laid out. The streets have their footpaths paved with brick, and are lighted with gas. In the centre of the town is the extensive earthenware manufactory of Messrs. Spode and Co, covering an area of several acres. The town-hall is a neat building, well adapted to its purposes, with an engine and lock-up-house beneath. The church is a modern structure, of Gothic architecture, erected in place of an older one now pulled down: it has a tower 112 feet high. There is a handsome and commodious national school adjoining the churchyard. The population of the township of Penkhull, in which the town stands, was, in 1831, 5876, of whom 609 men were employed almost entirely in the manufacture of earthenware. The earthenware manufactories of Stoke are not numerous, but are among the most important in the district. The market is on Saturday, and is well supplied.

Tunstall-court has risen during the present century from a mere hamlet of sixty houses. It is on the declivity of a considerable eminence, about four miles north from Newcastle-under-Lyne. It has a new church, built about ten years since, and three Methodist meeting-houses. The spacious market-place was formed in 1815. There are a market and court house, with lock-up cells for offenders. The

population of Tunstall-court township in 1831 was 3673, of whom only 19 men were returned as employed in manufacture, but there was obviously some mistake in the return here. Earthenware and blue tiles are manufactured; and there are corn-mills and chemical-works. The market is on Saturday.

These are the principal places in the borough, the total population of which, in 1831, was as follows:—

	Houses. Inhab.	Houses. Uninh.	Houses. Build.	Families.	Population.
Burslem, township .	2731	94	11	3042	12,250
Rushton Grange, vill*	..	..	..	..	..
Sneyd, hamlet .	170	4	..	186	963
Hanley, chapelry .	1321	76	18	1402	7,121
Lane-End, do. .	278	18	..	299	1,488
Shelton, township .	1810	61	26	1971	9,267
Penkhull, do. .	1071	38	12	1215	5,876
Boothen, do. .	21	..	..	22	121
Fenton Vivian, do. .	189	18	..	222	1,062
Fenton Culvert, do. .	535	54	21	629	2,708
Longton, do. .	1593	201	7	1815	8,120
	9749	564	95	10,803	47,916

In the borough, or in its immediate neighbourhood, about 4400 men, with their families, were, in 1831, engaged in the manufacture of earthenware. A number of men are employed in the adjacent coal-works. Coals, marl, and potters' clay are dug in the neighbourhood. The potters are generally steady men, as attested by the fact that a greater number reside in houses belonging to themselves, purchased by their savings, than in any other place of equal population in England. Many of them rent small plots of ground, on which they raise in rotation crops of potatoes, wheat, and oats; the straw is used in packing the earthenware. The hazel-rods and coppice-wood of the surrounding district are used in considerable quantity in making crates to pack the earthenware. The Trent and Mersey Canal and the Caldon Canal run through the heart of the Potteries. The Manchester and Birmingham Railway was designed to run through them, but the line has been altered.

The living of Burslem is a rectory, of the clear yearly value of 455*l.*, with a glebe-house; the benefice of the new church at Burslem is a perpetual curacy, of the clear yearly value of 109*l.* The benefice of the new church at Tunstall is a perpetual curacy. The living of Stoke-upon-Trent is a rectory, of the clear yearly value of 2717*l.*, with a glebe-house. The benefices of Hanley, Shelton, Lane-End, and Longton are perpetual curacies. The clear yearly value of Hanley is 226*l.*, and of Lane-End, 151*l.*, each with a glebe-house. All these places are in the rural deanery of Newcastle and Stone, in the archdeaconry of Stafford and diocese of Lichfield. There were in the borough, in 1833, besides private day-schools, two infant-schools, with 164 children: one at Hanley and one at Lane-End; three national schools, namely, the Hanley and Shelton school, with 215 boys and 156 girls; the Stoke-upon-Trent school, with 120 boys and 187 girls; and the Lane-End school, with 103 boys and 64 girls; a Lancasterian or British school at Shelton, with 150 boys and 100 girls, and a Roman Catholic school in Lane-End, with 90 girls. The national schools are attended by many hundred children in addition on Sundays, and there are many Sunday-schools, some of them very large. There are a literary society at Tunstall, and a mechanics' institution called the Pottery Mechanics' Institution. The North Staffordshire Infirmary is in the township of Shelton; it is a spacious and commodious brick building.

The number of voters on the register for 1835-6 was 1445; for 1839-40, 1623, showing an increase in four years of 178. The number of qualifying houses (*i.e.* houses worth 10*l.* a year) in proportion to the population is unusually small, rents being very low, owing to the abundance of building-ground and the cheapness of building materials. The borough returns two members to parliament.

(Shaw's *History of the Staffordshire Potteries; Parliamentary Papers.*)

STOLE, originally a long vestment, a matron's robe, from the Latin *stola*, and that from the Greek στολή. Pitiscus, in his 'Lexicon Antiquitat. Roman.,' has a long article upon the *stola* as worn by the antients.

In later times stola was the term more particularly applied to a broad strip of cloth or stuff, with three crosses upon it, worn by priests of the Romish church as a sacerdotal vestment, with whom it was also called *Orarium*. 'Orarium est stola,' says Lyndwood, in his 'Provinciale,' 'qua sacerdos in omni obsequio divino uti debet, et sao collo imponitur ut significet se jugum Domini suscepisse.'

The stole or orarium, according to Palmer (*Origines Liturgicæ*, vol. ii., pp. 316, 317), has been used from the most primitive ages by the Christian clergy. It is spoken of by the first council of Braga, A.D. 563; by Isidore Hispalensis, A.D. 600: the Council of Laodicea, in Phrygia, A.D. 360; Severianus Gabalitanus, in the time of Chrysostom; and many others (see Bingham's *Antiq.*, b. xiii., c. 8, § 2; and Gerberti, *Liturg. Aleman.*, tom. i., p. 240); and it has been continually used by all the churches of the west and east, and by the Monophysites of Antioch and Alexandria. 'The stole,' says Palmer, 'always called Ὀράριον by the Greeks, was fastened on one shoulder of the deacon's albe, and hung down before and behind. The priest had it over both shoulders, and the two ends of it hung down in front. The Eastern churches call the stole of the priests ἐπιτραχήλιον. Thus simply were the dresses of deacons and priests distinguished from each other in primitive times.'

The pall of the metropolitans was originally only a stole wound round the neck, with the ends hanging down behind and before.

That the word stole, in the sense of a sacerdotal vestment, was of early adoption into the English language, appears from the 'Saxon Chronicle' under the year 963, when Archbishop Dunstan, at the time of personally confirming King Edgar's grant of lands to the monastery of Peterborough, added that he himself gave, among other vestments, his *stol* to St. Peter. (Ingram's *Sax. Chron.*, p. 156.)

STOLE. [STEM.]

STOMACH. One of the most constant characters by which animals are distinguished is the possession of an internal digestive cavity, in which their food is received and subjected to a peculiar chemical change before it is appropriated to the nutrition of the different parts of the body. In some animals the chemical change is effected in every part of the cavity; in others it goes on in one portion of it exclusively, and this portion is named the stomach. Its forms in each of the chief divisions of the animal kingdom are considered in their appropriate articles: in the present, therefore, the anatomy and a part of the physiology of the human stomach alone will be described. Most of the important facts concerning its office are detailed in the article DIGESTION; but since that was published, the knowledge of the process has been greatly increased by some researches into the minute structure of the stomach, the nature of the digestive substance, and the results of artificial digestion.

The human stomach is a membranous sac of an irregularly conical form, which lies almost transversely across the upper and left portion of the abdominal cavity. [ABDOMEN.] Its larger extremity is directed to the left, its smaller to the right. To the left it is in contact with the spleen; to the right, with the liver: above it is covered by the diaphragm, and, at about one-third of the distance from its left to its right extremity, it communicates, by an orifice called the cardia, with the œsophagus: at its right end it opens by another orifice, named pylorus, into the intestinal canal. Of these orifices the pyloric lies rather lower than the cardiac: they are separated from each other by the upper and shorter border, or small arch, of the stomach, the greater part of the cavity being formed as if by the dilatation of the left side of the œsophagus into a great cul-de-sac and great arch, which form the left and inferior boundary of the stomach.

The coats or walls of the stomach are composed of three distinct membranes, connected by a firm but very extensible cellular tissue. The external or peritoneal coat is a layer of fine compact cellular tissue, woven into a thin membrane, and covered by a fine cuticle or epithelium, from which, like all the other organs within the abdominal cavity, it obtains a perfectly smooth and polished surface. The peritoneum invests every part of the stomach except the upper and lower borders, where there are spaces in which the trunks of the blood-vessels run, and from each of which the peritoneum is continued in a double layer to form the greater and less omenta. [OMENTUM.] Its only purpose seems to be to permit the stomach to move easily upon the adjacent organs.

Between the peritoneal and the internal or mucous

* Included, we believe, in Burslem township.

membrane, there is a stratum of loose cellular tissue, in which are inlaid the fibres of the middle or muscular coat. This is composed of three different sets of fibres, resembling in their structure those of most involuntary muscles. [MUSCLES.] The fibres in the first and most superficial layer run longitudinally: they are continued from those of the outer coat of the œsophagus, which, at the cardia, expand or radiate, and pass in fasciculi at some distance apart, from left to right, along both the anterior and posterior surfaces of the stomach. The second layer is composed of circular fibres which form numerous fasciculi, each of which encompasses a considerable portion of the circumference of the stomach. The third and internal layer consists of two principal fasciculi of muscular fibres, which proceed from the cardia and expand over the great cul-de sac and middle portion of the organ. By the differently combined contractions of these fibres, all the motions of the stomach, described under DIGESTION, are performed.

The interior or mucous coat of the stomach is that in which the essential apparatus for the production of the digestive material is placed. To the naked eye it appears a soft spongy membrane, about one-tenth of an inch thick, with a polished slippery surface. After death it varies considerably in its colour, but during life has a light pinkish tinge, and, accordingly as the stomach is distended or contracted, is either perfectly smooth or is thrown into various deep and irregular but chiefly longitudinal wrinkles. At the pylorus it forms a deep fold, between the two layers of which are strong fasciculi of circular muscular fibres: these constitute the pyloric valve, by which the aperture between the stomach and intestines is guarded. At the cardiac orifice the boundary between the mucous membrane of the stomach and that of the œsophagus is marked by a jagged line, at which the thick and opaque epithelium of the latter terminates, and the much finer epithelium lining the stomach commences.

The more intimate structure of the mucous membrane can be seen only with the aid of the microscope. If its surface be examined with a lens whose magnifying power multiplies diameters about forty times, it appears to be covered by minute polygonal fossæ, from $\frac{1}{100}$ to $\frac{1}{250}$ of an inch in width, surrounded by narrow sharp-edged borders, to which little leaf-like processes are sometimes attached. At the bases of each of these fossæ there are, at least during digestion, from six to ten minute apertures leading into tubes which pass vertically into the substance of the mucous membrane. A thin section of the membrane, made perpendicularly to its surface, shows that nearly its whole substance is composed of these tubes, which are minute cylindrical glands, opening on the surface in the fossæ just described, but closed below, and set compactly side by side in groups. They vary in length from one-fourth of a line to nearly a line, the longest being situated near the pylorus. Near their bases they measure about $\frac{1}{300}$ of an inch in diameter, and near their orifices about $\frac{1}{500}$. Their lower closed extremities sometimes seem (but only seem) a little convoluted or baccated. They lie in every part of the mucous membrane, but are largest and most densely set, so that they are actually in contact, near the pylorus; a few of them are branched, two or more tubules opening by a single orifice. The small blood-vessels pass vertically in the cellular tissue between the groups of tubules from the submucous tissue to the surface of the stomach, on which they form an angular network, marking out the borders of the shallow fossæ.

The walls of these little tubular glands are composed, near the surface of the stomach, of a fine structureless membrane, and, at the deeper part, of minute nucleated cells adhering by their edges. Their office seems to be the production of cells containing the fluid for digestion. In different parts of the stomach, and at different times, they vary in the nature of the substance which they contain; and it seems probable that these variations depend on whether the tubes are, or are not, engaged in producing digestive fluid. Those which are so occupied are completely filled with cells in different stages of development; those which are inactive are empty, and have their walls lined internally by epithelium, similar to that which invests the interior of the stomach. In the production of the cells containing the digestive fluid, small granules are first generated in the deeper part of each tubular gland: these, coalescing by twos or threes, form nuclei, on which the cells are developed according to the ordinary mode of formation of primary cells. [NUTRITION.] The cells are of an oval form, about $\frac{1}{2000}$ of an inch in length; and, as fast as they are produced, they are pushed towards the orifices of the tubes, from which, while digestion is going on, they are discharged in such numbers as to form, with a small quantity of fluid separated at the same time, the thick layer of mucus by which the whole interior of the stomach is lined, and by which the portions of food are invested. In the intervals between successive acts of digestion, it seems probable that the orifices of the tubules are closed by small portions of epithelium similar to that by which they are lined, and which are elevated and broken through for the discharge of the cells as soon as the active process commences.

During digestion there are also often found, just beneath the surface of the mucous membrane, around either the cardiac or pyloric orifice, and along the lesser arch of the stomach, a number of small closed sacculi, filled with an opaque white fluid containing cells, which, when their contents are matured, burst and discharge them into the interior of the stomach. But the exact office of these bodies (which have been generally described as the gastric follicles, or lenticular glands of the stomach) is not known; they are certainly not always present, but, probably, are produced rapidly while digestion is going on, and, having discharged their contents, are again rapidly absorbed.

The distinctive character of the fluid contained in the cells formed by the tubular gastric glands is, that it holds in solution a peculiar chemical principle, to which the name of Pepsin has been given, and which in conjunction with a small quantity of acetic or muriatic acid constitutes the true gastric juice or digestive fluid. It may be extracted from the mucous membrane of the stomach after death, and if a slightly acidulated solution of it be mixed with food, the latter will pass through the same changes as are produced by digestion in the living stomach or in the gastric fluid obtained during life, and will be at last converted into chyme. [DIGESTION.]

The simplest proceeding for observing this process of artificial digestion, is to macerate a stomach (if taken from a ruminant animal, it must be the fourth stomach) in about twice its weight of lukewarm water, to which about $\frac{1}{10}$th part or any sufficient quantity of muriatic or acetic acid has been added, to make it taste pretty strongly sour. The maceration having been continued for eight or ten hours at a temperature between 80° and 100° Fahrenheit, the liquor may be poured off, and will serve for all ordinary experiments. A purer digestive fluid is obtained by removing the mucous membrane from the middle portion of a pig's stomach (which contains the greatest number of active glands), washing it carefully, digesting it for a few hours in about six ounces of distilled water at a temperature of 90° Fahrenheit, and then again repeatedly washing it in cold water till it begins to be a little putrid. The liquor in which it has been macerated and washed must be filtered, and acetate of lead being added to it will be precipitated in combination with the pepsin. The precipitate should then be repeatedly washed, and a stream of sulphuretted hydrogen gas passed through the water in which it is kept suspended by constant stirring. By this means the lead is removed; and the fluid, being again filtered and evaporated to the thickness of syrup, must be mixed with absolute alcohol, which will precipitate the pepsin combined with a small quantity of acetic acid in white flocculi. These may be collected on a filter and dried in the air.

Slightly acidulated water, in which $\frac{1}{60000}$ part of its weight of pepsin thus prepared is dissolved, forms an active digestive fluid, and portions of meat, albumen, &c. are converted into chyme after a few hours immersion in it, at a temperature between 70° and 100° Fahr. This peculiar property, its power of coagulating milk, and its not being precipitated from its acid solutions by ferro-cyanide of potassium, are the chief qualities which distinguish pepsin from albumen; in all other chemical characters they closely agree.

The best method of exhibiting the action of an artificial digestive fluid is, to put small pieces of boiled white of egg, bread, meat, &c. into several chemical test-tubes; and to add to those in the first tube some solution of pepsin with acid, to those in the second some of the same solution without acid, to those in the third some water with the same proportion of acid, and to those in the fourth some water alone. After remaining for a few hours at the temperature already mentioned, the substances in the first tube alone will have under-

gone any material alteration. In about twenty-four hours, they will be nearly or completely dissolved, and will have lost many of their chemical properties; the albumen, for instance, being no longer coagulable, but resolved into osmazome, salivary matter, and some new substance, while the same materials in the other tubes will be still unchanged. In short, the changes that may be effected by this artificial fluid are exact repetitions of those described under DIGESTION as resulting from the gastric juice. To this article therefore we may again refer, only observing that all the facts of artificial digestion render it nearly certain that the similar process which takes place in the living body is not due to any vital property of the gastric fluid, but to its peculiar chemical condition; though in what this peculiarity consists, and whether the acid or the pepsin be the actual solvent principle, are questions at present altogether undecided.

The best works in which the subjects here considered may be further studied, are Sprott Boyd, *On the Structure of the Mucous Membrane of the Stomach*, in *Edinburgh Med. and Surg. Journal*, 1836; Purkinje, *Isis*, 1838, and Müller's *Archiv.*, 1838; Bischoff, *Ueber den Bau der Magenschleimhaut*, Müller's *Archiv.*, 1838; Krause, *ibid*, 1839, cxx.; Eberle, *Physiologie der Verdauung*; Schwann, Müller's *Archiv.*, 1836; Wasmann, *De Digestione*, and the *Physiological Systems of Müller and Wagner*.

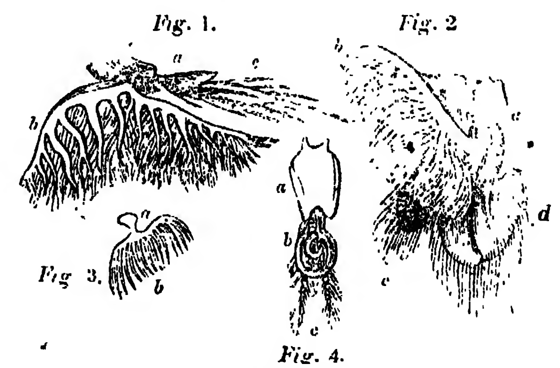
STOMAPODS. M. Milne Edwards comprises in the order *Stomapodes* all the podophthalmous crustaceans which are deprived of thoracic branchiæ lodged in internal cavities.

ORGANIZATION.

This division is entirely composed of swimming crustaceans, whose body is elongated, and whose general form often approaches closely to that of the macrourous decapods; but in those animals the concentration of the rings of the head and thorax is carried less far. In the greater part of the Stomapods the ophthalmic and antennular rings are not confounded with the rest of the head, and they even sometimes acquire a remarkable development. As in the other *Podophthalma*, there always exists a *carapace*, which is formed by the enlargement of the dorsal arch of the antennary or mandibular rings: but the dimensions of this buckler vary greatly. Sometimes it covers nearly the whole of the thorax, and only leaves exposed a portion of the last ring of that part of the body; sometimes, whilst it prolongs itself above the thoracic rings, it only adheres to those which are near the mouth, and leaves the others free and complete under its lower surface. In other cases it does not reach the four or five last rings of the thorax, which then resemble those of the abdomen. In form it varies too much for general description. The *thorax* is generally elongated, and entirely composed of segments moveable upon each other. Sometimes all the rings of this part of the body are united into a single piece. The conformation of the *abdomen* varies still more; this portion of the body presents in general nearly the same disposition as in the macrourous decapods, and terminates by a great caudal fin composed of appendages of the sixth ring and the following segment: but in some stomapods the abdomen is rudimentary. The disposition of the limbs is equally variable. The *eyes* are always carried on a first pair of moveable appendages, the length of which is often very considerable, and whose disposition is essentially the same as in the macrourous decapods. The first pair of *antennæ* are rather long, and terminate in two or three multiarticulate filaments; their peduncle is always cylindrical, and they can never be bent back under the front as in the brachyurous decapods. They are inserted below the eyes, near the median line, or externally to the base of those organs. The second pair of antennæ vary still more; their conformation however generally approaches that in the SHRIMPS. The basilary joint of their peduncle nearly always carries above a great ciliated blade, and they terminate by a long multiarticulate filament. In the greater part of the Stomapods they are inserted outside the first pair, nearly on the same transversal line. The distance which separates the mouth from these appendages is generally very considerable; and the carapace never recurves below, so as to form round that aperture a well determined frame serving to lodge the jaw-feet, as in the greater part of the decapods. In the majority the buccal apparatus is more simple than in the preceding order, and is only composed of an upper lip, a a pair of mandibles, a lower lip, two pairs of jaws, and a single pair of jaw-feet; these last organs are either altogether wanting, or are transformed into natatory feet, and nearly always the seven following pairs of members are all so formed as to constitute natatory or prehensile feet. It is also worthy of note, that in the stomapods the second pair of jaws never carry at their base a lamellar appendage analogous to the valvule, which, in the decapods, fulfils functions so important in the mechanism of respiration; and this modification of structure is a natural consequence of the absence of a respiratory cavity which includes the thoracic branchiæ, as in the preceding order.

There are generally seven or eight pairs of feet, often presenting the same mode of conformation. They are nearly always provided with an appendage, which may be considered as the analogue of a palp. There is often found also at the base of many of the anterior feet another soft and vesicular appendage, which has sometimes the form of a *galette*, and which represents the flagrum, an organ which, in the greater portion of the decapods, is lamellar and of a horny consistence; but which, in certain shrimps, presents a structure similar to that in the stomapods. Three of the last pairs, or a greater number, are always natatory; the first pair, or even the four first, are often prehensile; but they never terminate in a didactylous pincer, as in the decapods: they are subcheliform, that is to say, nothing more than a moveable claw which falls on the preceding joint. The greater part of these organs are approximated to the mouth, or even applied against it; a disposition which has been the cause of the appellation *Stomapods*. The abdominal members present nothing peculiar; their number is nearly always six pairs.

The *branchiæ* of the stomapods are always external, and present in general a more complicated structure than those of the decapods. Instead of being composed of lamellæ or simple filaments, they are framed of cylinders ranged in parallel order, giving origin to other smaller cylinders, which, in their turn, are equally fringed. Sometimes these ramose branchiæ are fixed at the base of the thoracic feet, and suspended under the thorax: but in general they spring from the basilary joint of the abdominal false feet: in some of the order they are reduced to a rudimentary state; in others nothing is to be seen which can be considered as a special organ of respiration; and, in such cases, there is every reason to believe that this function is exercised by the general surface of the teguments.



Branchiæ of Stomapods.

1, one of the branchiæ of *Thysanopoda* a, base of the posterior foot; c, palp; b, branchiæ. 2, a branchia of *Squilla* a, base of the false foot; b, branchia; c, d, the two terminal branches of the false foot. 3, a, one of the branches of this ramose branchia; b, the branchlets (ramuscules). 4, one of the abdominal false feet of *Cynthia*. a, basilary joint; b, branchia; c, lamellar appendages.

The apparatus of *circulation* differs much from that of the decapods. In the *Squillæ*, the only stomapods which have been anatomically examined, the heart, instead of being nearly quadrilateral, and situated towards the middle of the thorax, has the form of a long cylindrical vessel, which extends throughout the length of the abdomen: the arteries which spring from this tubular heart are distributed in a peculiar manner; and the principal venous sinuses, instead of being situated on the thorax, occupy the abdomen.

The *stomach* of some stomapods presents vestiges of the solid framework, which, in the decapods, is armed with teeth serving to bruise the aliments in the interior of the digestive cavity; but in general nothing similar is to be found. The structure of the *liver* also varies: and in those species in which the organs of *generation* have been examined, remarkable peculiarities have been observed in their disposition. The *nervous system* in this order presents also

modifications which have not been found in the decapods; and its disposition varies too much to enable M. Milne Edwards to say anything general of it.

Such is the organization of the stomapods, as stated by M. Milne Edwards, an order less numerous than the decapods, but comprising crustaceans which differ much from each other, both in general form and in the particular structure of their principal organs.

Systematic Arrangement and Natural History.

The same excellent author, and we can follow none more deeply versed in the subject, divides the stomapods, after the example of Latreille, into three families:—the *Caridoïdes*, the *Bicuirassés*, and the *Unicuirassés*.

1. *Caridoid Stomapods.*

The crustaceans arranged by M. Milne Edwards under this family bear a close resemblance in their general form, he observes, to the family of *Salicoques* or Shrimps; and indeed till lately their position had been in the order *Decapoda*, where they constituted a small and peculiar family under the name of Schizopoda; but the anatomical investigations made by M. Milne Edwards with respect to the organs of respiration in these animals, and the discovery of new species which establish a passage between the former and Phyllosoma, led him to propose new limits between the decapods and stomapods, and to place the schizopods in the second of those groups. This innovation, he remarks, had been adopted by Latreille in his last work (*Cours d'Entomologie*): and that scientific naturalist gave to the new division of the order *Stomapods*, established for the reception of those *Podophthalmous Crustaceans* which are deprived of internal thoracic branchiæ, but are similar to certain *Salicoques* in their external form, the name of *Caridoids* from that resemblance.

Family Character.—Body thick, and slightly compressed laterally; head confounded with the thorax, and all the rings of the last-named part (with the exception, sometimes, of the last, or of the two last) completely united together and soldered above with the carapace. *Abdomen* considerably developed, and terminating by a great fin composed of five laminæ or blades, disposed in a fan-shape, as in the *Macrourous Decapods*. The *carapace* descends on each side against the base of the feet; covers the whole, or nearly the whole, of the thorax, as well as the head; and presents only a rudimentary rostrum in front: there is no moveable plate in place of this frontal prolongation, as in *Squilla*, and the ophthalmic ring is in general very short and naked. The disposition of the eyes, of the antennæ, and of the pieces of the mouth, varies. The thoracic plates are all slender, natatory, and resemble each other; but their number varies much. The *abdomen* is composed, as ordinarily, of seven rings, the five first of which carry natatory false feet, whilst the seventh forms, with the appendages of the sixth segment, the caudal fin: these last appendages consist each of a small very short basilary joint, and of two great terminal plates disposed as in the macrourous decapods. Finally, the conformation of the respiratory apparatus varies: sometimes the branchiæ do not exist; sometimes vestiges of them are found at the abdominal false feet; and sometimes they are, on the contrary, very much developed, and suspended under the thorax. (M. E.)

M. Milne Edwards divides the *Caridoïds* into two small tribes, the *Mysians* and the *Luciferians*.

1st tribe. Mysians.

This tribe resembles the *Salicoques* so closely, that till lately the species forming it had been arranged under the *Macrourous Decapods*, where they constituted the family designated *Schizopods*.

Character of the Tribe.—*Carapace* extending to the base of the ocular peduncles, and presenting in general in the middle of the front a rudimentary rostrum. *Antennæ* inserted on two lines and formed as in the shrimps, excepting only that the lamellar appendage of the second pair is less. *Mouth* situated very near the base of these last, and composed essentially of a *labrum*, a pair of mandibles furnished with a palpiform stem, a lower lip, and two pairs of lamellar jaws: sometimes the whole suite of limbs, which succeed to those appendages, belong to the apparatus of locomotion; but, in other cases, one or even two pairs of these organs constitute jaw-feet, without their form always differing much from that of the thoracic feet. These feet each present two branches which are well developed and carried on a very short basilary joint, so that they seem to be bifid from their base. *Abdomen* of moderate length; *false feet* fixed to its first rings, sometimes rudimentary. (M. E.)

Under this family M. Milne Edwards arranges the genera *Mysis*, *Cynthia*, and *Thysanopoda*.

Mysis.

Generic Character.—*Body* narrow, elongated. *Carapace* covering the anterior extremity of the trunk as well as the greater part of the thorax, and bent down on each side so as to apply itself against the base of the feet. It is free laterally, and does not adhere to the last rings of the thorax; anteriorly it is narrowed considerably, and terminates by a small flattened and very short rostrum; its posterior border is deeply notched. *Eyes* large, short, and with their base hidden under the anterior part of the carapace. *Internal Antennæ* inserted below the eyes, near the median line; peduncle of the same form as in the shrimps, and carrying at its extremity two multiarticulate and rather long filaments. The *second pair of antennæ* inserted below the preceding, and, equally, directed forwards: the first joint of their peduncle gives origin to a very elongated lamellar appendage, which is ciliated on the internal border that covers the base of those organs, as in the shrimps. The two succeeding joints of the peduncle are slender and cylindrical, and the terminal filament is filiform, multiarticulate, and longer than the upper antennæ. *Mouth* very much approximated to the base of the antennæ, and presenting, as ordinarily, an upper transversal lip succeeded by a pair of mandibles, a lower lip, two pairs of jaws, and a certain number of jaw-feet. *Mandibles* toothed on their internal edge and carrying a highly developed palpiform stem extending forward to a considerable length. The first pair of *jaws* each composed of two small flattened blades or flattened lobes ciliated on the internal border. Second pair of jaws larger and much resembling those of *Squilla*, without being however so narrow. They are lamellar and divided on the external side into four lobes, by more or less deep incisions; the last of these lobes is formed by the terminal joint, and the first belongs also to a distinct basilary joint; but the two median lobes are confounded together to their base, and would seem to belong to a single joint, the external border of which is dilated, rounded, and ciliated; the internal border of these organs is equally furnished with hairs. The *jaw-feet* are two in number; but differ very little from the true feet. The first pair are short, rather long at their base, and composed of three branches; the internal is pediform, divided into five joints, furnished with hairs, and bent back internally before the mouth; the median branch or palp is more elongated, and presents a very large basilary joint succeeded by a kind of ciliated strap (lanière) on each side, and composed of a very great number of small joints. Finally, the external branch or flabelliform appendage is represented by a semimembranous blade which is directed upwards and lodged between the carapace and the sides. The second pair of jaw-feet have the same form, but their internal branch is more elongated and they want the flabelliform appendage; as in the preceding, the last joint of their internal branch is lamellar, wide, short, and rounded at the end. The six pairs of thoracic feet, which succeed the buccal apparatus, and which are composed of members corresponding to external jaw feet and to the five pairs of ambulatory feet in the decapods, are all slender and divided into two branches; their length increases progressively from before backwards, and they are all formed for swimming only. The internal branch presents nearly the ordinary form, but terminates in an unguiform tarsus, which is hardly visible, and precedes a styliform joint, which seems multiarticulate, and is ciliated in its two borders. The external branch or palp is nearly as long as the internal branch, and has the same form as that of the jaw-feet. The four first pairs of feet carry no external branch or flabelliform appendage, whilst those of the two last are provided with it. In the males, those appendages are rudimentary, but in the females they acquire an extreme development and constitute great semicorneous blades bent in under the sternum, so as to form a species of pouch destined for the lodgment of the eggs, and of the young during the early part of their life; a disposition very analogous to that observable in the Isopoda. The two last rings of the thorax are entire, more or less completely exposed, and resembling those of the *abdomen*, which is elongated, nearly cylindrical, and gradually narrowed from before backwards: the dorsal portion of these last rings is not prolonged laterally so as to encase the base

of the false feet, as in the majority of the shrimps: it terminates by a great caudal fin, composed of five blades disposed in a fan-shape, exactly as in the macrourous decapods. Finally, the five first pairs of feet are rudimentary, and are only composed each of a small ciliated blade in the female: but in the male may be distinguished a peduncle and a terminal blade; the first and last pairs acquire sometimes a considerable development.

There is no vestige of branchiæ, either at the vault of the sides or at the base of the feet, or at the lower surface of the abdomen, and the only appendage which would seem to be modified in its structure so as to become more proper than the rest of the body to fulfil the functions of an organ of respiration, is the flagrum of the first pair of jaw-feet, whose disposition, for the rest, is nearly the same as that which may be remarked in a great number of crustaceans provided with branchiæ. Some authors give the name of branchiæ to the basilary joint of the external branch or palp of the thoracic feet, but without supporting this determination by any argument which might lead one to adopt it.'

Such is M. Milne Edwards's luminous description of this most interesting genus of crustaceans; but we must not overlook the distinguished labours of Mr. John V. Thompson, so well known for his accurate and original observations relating to the *crustacea* and other marine animals of the Irish seas. To the last-named zoologist, more than perhaps to any other, we owe our knowledge of the organization and habits of these *opossum shrimps*, as they have been named from the pouch or personal nest, above described, provided for the reception of their eggs and young. He closely examined the circulation of these animals, and has shown that their heart is elongated and occupies the posterior part of the thorax. Anteriorly it gives origin to a slender vessel which has its course above the stomach, and is continued backwards with a large abdominal artery; on each side, it receives a vessel which appears to be a branchio-cardiac trunk. The pulsations of the heart are so rapid that they resemble vibrations, and the blood is so transparent and so little coloured, that its movement is only to be distinguished by means of the globules floating therein. Mr. Thompson states that on observing with attention the termination of the posterior aorta at the end of the tail, a periodical action may be noticed, as of the opening and closing of a valvular opening on each side, accompanied each time by the filling of the corresponding end of a vessel of considerable size, lying on each side of the intestinal canal; and that these vessels or veins propel the blood towards the heart by successive contractions of their muscular fibres, and seem to be lost at length in a great sinus or auricle, lying beneath the heart. But Mr. Thompson adds that it remains to be ascertained by dissection, whether this is the case or not; he thinks however that there can scarcely be a doubt that the two large veins constitute the *venæ portæ*, and ultimately send their blood to the branchia.

The same diligent observer thus describes the *valvular pouch*:—'Attached to the base of each of the inner divisions of the two posterior pairs of feet in the *female*, is a large concave scale, strongly pectinate in front, of which the posterior is the outermost, largest, and most concave, lapping considerably over the anterior scale, so as to admit of a considerable extension of the size of the pouch which they form by meeting each other in front, in order to accommodate its capacity to the growth of the ova and young brood. In the *male*, in place of the valvular pouch of the female, we perceive attached to the inner part of the last pair of feet only, a single small hollow scale on each side, ciliate in front, and provided with a marginal row of slender hooks at the apex: these are probably an appendage of the male organs, which have a similar situation in the shrimps.'

Within this pouch in the female, the eggs, or rather embryos, Mr. Thompson informs us, are received when excluded from the ovarium, and enveloped in a mucous or subgelatinous secretion, and gradually developed without any visible attachment to the parent. 'The ova when first received into the pouch are considerably more advanced than those of the shrimps, crabs, &c. on their first expulsion, and by no means so numerous, a circumstance more than compensated by the rapidity with which one brood succeeds another during the whole of the spring and summer months. The number of broods produced by one individual, as well as the time occupied in their evolution, have not been determined; but the changes which the embryo undergoes in configuration are sufficiently obvious; in the present instance, these cannot be considered as metamorphoses, but simply a gradual development of parts; hence the *Schizopoda* may be regarded as one exception to the crustaceans undergoing transformations, another character by which they are separable from the true shrimps, &c. The first change which is perceptible in the ova after their reception into the external pouch, is a slight elongation at one end, and the appearance of two short members on each side; this elongation, which proves to be the tail, increasing in length, shortly after becomes forked at the end, accompanied by a proportional growth in the four lateral members, and which are the rudiments of two pair of antennæ in the perfect animal; the embryo going on thus with a progressional development from day to day, begins to assume a more complete form, and an approximation to that of the parent, in which stages the divisions of the abdomen, the tail, the pedunculate eyes, and the various members are sufficiently distinct; a still more close resemblance to the perfect animal is attained before the young are finally excluded, which is effected by the parent spreading open the valves of its pouch, when the whole brood emerge at once into the ambient element, and, in most of the species, continue associated with the community from which they sprang: the slight differences which they now present (and which are necessary to be known in order to preclude the possibility of their being mistaken for individuals of a different species) affect only the inner rows of feet, the subabdominal fins, the outer antennæ, and the tail; the first of these, in place of the multarticulate termination, have but one or two short joints and a curved claw superadded to the end of the tibiæ, and hence this division of the limb is shorter in proportion; the subabdominal fins consist only of a linear joint surmounted by a few bristly hairs; the outer antennæ differ in no other respect than in the ciliated scale which is attached to their base being shorter and less developed, as is also the brush of hair in the males; the three intermediate scales of the tail are proportionally shorter, but yet present the character peculiar to the species in their form, indentations, and appendages, so as to testify the acuteness of Dr. Leach in having fixed upon this part to distinguish the species from each other. What is further remarkable in the embryos is the way in which they are arranged within the pouch from the moment they assume an elongated form; their heads being towards the breast of the mother, with the curvature of the tail part suited to that of the outline of the pouch, and the large size and blackness of their eyes.'

The different stages of development, &c. are illustrated by Mr. Thompson, in his 'Zoological Researches,' the work in which he gives the above description, and which is most valuable for the insight afforded to the naturalist into some of the most curious and hitherto obscure phenomena manifested by the crustaceans generally. The student will, no doubt, be led to compare the development of the young opossum shrimps with that of the quadrupedal MARSUPIALIA.

Geographical Distribution of the Genus.—The species swim freely in the sea in numerous troops, and are particularly abundant in the north, where, according to Otho Fabricius, they constitute a principal portion of the food of the whale-bone whales (*Balænæ*). Captain James Ross, R.N., states that *Mysis flexuosus* (*Cancer flexuosus*, Müller), though but sparingly found in the seas of Europe, inhabits some parts of the Arctic ocean in amazing numbers, and constitutes the principal food of the prodigious shoals of salmon that resort thither in the months of July and August, and upon which the inhabitants of BOOTHIA depend, in great measure, for their winter store of provisions. He further observes that it is also the chief food of the whale, by which such a prodigious quantity of fat is produced in the body of that immense animal. Captain Ross adds that during the summer these crustaceans assemble in vast myriads at the mouths of rivers, but in the winter are more generally distributed along the whole line of coast, and, together with the *Argonauta Arctica* (*Clio helicina* of Phipps and Gmelin—HYALÆIDÆ, vol. xii., p. 372), are to be seen in every crack that opens with the tide, even at the coldest period of the year. The natives call this crustacean *[illegible]kak*. (*Appendix to the Second Voyage of Captain Sir John Ross.*)

M. Milne Edwards divides the genus *Mysis* into the following sections:—

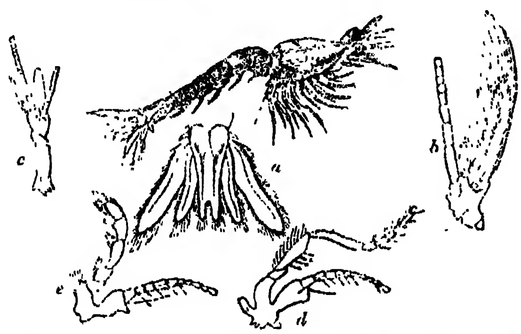
1. *Species which have the middle blade of the caudal fin bifurcated*

Example, *Mysis spinulosus*, Leach.

Description.—Rostrum depressed and triangular, and not more than the third of the length of the ocular peduncles. Carapace extending nearly on the penultimate thoracic ring. Peduncle of the internal antennæ stout and very short. Lamellar appendage of the external antennæ narrow, of the same length (width?) to the end, and ciliated within and at the end. Median blade of the caudal fin furnished with spines on its lateral borders, and deeply notched at the end: internal blades of the lateral appendages narrowing gradually towards the end, and the external blades very obtuse. Length about 10 lines; colour brownish, with a small star in the middle of each of the rings of the abdomen.

Locality.—The British Channel and the coasts of La Vendée. (M. E.)

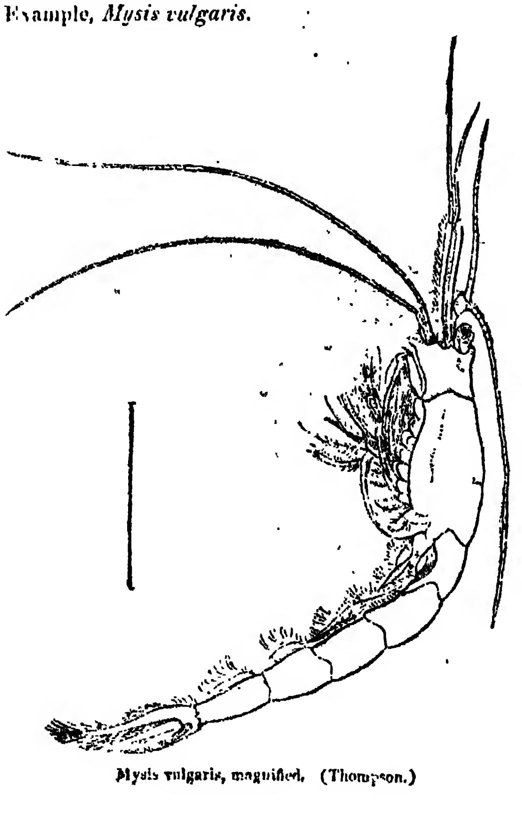
M. Milne Edwards gives the following as synonyms of this species:—*Praunus flexuosus*, Leach; *Mysis Leachii*, Thompson (*Zool. Res*). Leach's *Mysis Fabricii* does not appear to M. Milne Edwards to differ notably from *M. spinulosus*, especially if one may judge of it from the figure given of it by Desmarest; but at the same time, he observes, one ought not to forget that Latreille has represented, in the atlas of the 'Encyclopédie,' the lamellar appendage of the external antennæ as being ciliated externally as well as internally; a disposition which, if it really exist, would be characteristic.



Mysis Fabricii magnified. *a*, The last ring of its body, or its terminal fin; *b*, base of a lateral antenna; *c*, base of an intermediate antenna, *d*, one of the second pair of jaw feet; *e* one of the first four. These parts highly magnified. (Desm.)

2. *Species which have the median blade of the caudal fin entire at the end.*

Example, *Mysis vulgaris.*



Mysis vulgaris, magnified. (Thompson.)

Description.—Rostrum moderate; internal antennæ short, having their peduncle formed as in *M. spinulosus;* lamellar appendage of the external antennæ as in *Mysis longicornis;* lateral and middle fins of the caudal fin diminishing gradually in width from their base to their extremity; length about an inch; colour greyish.

Locality, Habits, &c.—Common on the Irish coast. Abounding in the Lee, even up to Cork, from the early part of spring to the approach of winter, according to Mr. Thompson, who states that during the still period of the tide at low-water, they repose upon the mud and stones at the bottom of the river, and, as the tide rises, may be observed forming a wide belt within its margin, the youngest swimming nearest to the shore, the oldest farther out and in deeper water. They appear, he adds, to be mostly females, the males being few in proportion, and they swim in a horizontal position, contributing towards the food of various young fish, from which they frequently escape by springing up out of the water.

Cynthia. (Thompson.)*

Generic Character.—Body slender and of the same form as in *Mysis;* but the carapace of *Cynthia* is smaller and terminates anteriorly by a small rostral prolongation; behind it a certain number of thoracic rings are exposed. *Eyes* stout and short, of moderate length. First pair of *antennæ* excavated at their base to make room for the eyes; their peduncle is stout, and they have two terminal filaments. The second pair of antennæ are inserted below the preceding, as in *Mysis*, but they are much smaller; the lamellar appendage which covers their base is shorter than the peduncle of the upper antennæ. Conformation of the buccal apparatus nearly the same as in *Mysis:* palpiform stem of the mandibles very large; second pair of jaws lamellar and divided on the internal side into many lobes. The eight pairs of limbs which succeed the jaws, ought, according to Mr. Thompson, to be considered as natatory feet; but M. Milne Edwards does not agree in that opinion, and the latter believes that the first pair of these organs also belong to the buccal apparatus, and constitute jaw-feet. In fact, observes M. Milne Edwards, those appendages, although more elongated than in *Mysis*, are bent back just in the same way as in that genus below the jaws, and their internal branch terminates by an enlarged joint, which is proper for retaining the aliments during mastication, whilst the feet terminate in a small hooked nail. The middle branch or palp of those jaw-feet is formed as in *Mysis*, but the flagrum or external branch, which, in the last-named genus constitutes a great membranous blade, appears to be completely wanting. The first pair of thoracic limbs differ also a little from the six last pairs of feet; they are more enlarged, and terminate by a lamellar joint, whose borders are ciliated; but nevertheless, by reason of their length and their position, they ought, remarks M. Milne Edwards, to be considered as assisting in locomotion, and they furnish us with a new example of the gradual manner in which the passage is effected between animals in which the same organs are modified in their structure to serve different purposes. In *Cynthia* the number of thoracic feet amounts to seven pairs, and in their structure and functions they do not differ remarkably from the same organs in *Mysis;* their two branches are equally well developed, only the penultimate joint of the internal stem is stouter, does not narrow towards its end, is not ringed so as to appear multiarticulate, and the terminal nail is larger. M. Milne Edwards observes that the conformation of the appendages which probably exist on the posterior feet of the females, and which to all appearance ought to fulfil the same functions as in *Mysis*, is not known; in the males may be remarked, at the base of the posterior feet, a small blade which represents the flabelliform appendage. *Abdomen* formed as in *Mysis*, excepting that the false feet fixed to the five first rings are very well developed, and of the same form as in the shrimps; each of these limbs is composed of a very stout peduncular joint and of two long blades, which are multiarticulate and ciliated on their edges. *Branchial appendages* of a particular form are attached to the extremity of the peduncles of the false feet behind the terminal blades; these appendages consist of a membranous cylinder bifurcated near its base, each of whose branches is rolled upon itself.

Example, *Cynthia Thompsonii.*

Description.—Rostrum very short; carapace extending to the last ring of the thorax, and but little narrowed for-

* Appropriated by Savigny to certain *Ascidians.* [CYNTHIA.]

wards; peduncle of the internal antennæ of the length of the lamellar appendage of the external antennæ, and having the last joint furnished within with a small piliferous scale; median blade of the caudal fin long, truncated at the end, and furnished laterally with spines; external blades shorter than the middle ones, and only having hairs or spines on their internal border and at their extremity; middle blades furnished with spines on their internal border; length about four lines.

Localities.—The Atlantic Ocean, between Madeira and the Antilles. (M. E.)

N. B. M. Milne Edwards observes that the *Cynthiæ* are of small dimensions, and seem to have the same habits as the species of *Mysis*, with which last they are frequently found. He further remarks that the males only have been as yet observed, and that possibly, when both sexes are known, it may be necessary to modify the characters assigned to this genus.

Thysanopoda. (M. Edwards.)

M. Milne Edwards states that these crustaceans resemble the shrimps greatly in the general form of their body, but are distinguished from the Decapods, as well as the other Stomapods, by the disposition of their respiratory apparatus. The branchiæ, he tells us, are each composed of a kind of stem, whence spring, at a right angle, a certain number of lateral branchiæ, whose inferior border is in its turn furnished with a series of long cylindrical filaments. This mode of organization is, he observes, very analogous to what may be seen in the *Squillæ*, but the branchiæ (see the cut, p. 77), instead of being inserted in the abdomen, as in the last-named crustaceans, occupy the thoracic part of the body, as in the Decapods. Nevertheless they are not enclosed in particular cavities, as in that order; they are situated on the exterior of the body, and float freely in the water with which the animal is bathed. They are fixed at the base of the eight pairs of thoracic feet, and their length increases from before backwards.

Generic Character.—External form resembling that of *Mysis*. *Body* presenting the same divisions as in the macrourous decapods. *Carapace*, which covers the head, hiding also the whole of the thorax. *Abdomen*, whose length much exceeds that of the cephalo-thorax, extended backwards, and composed of seven segments, the three median of which present on their posterior and superior borders a small spine, directed backwards. Carapace terminated anteriorly by a small pointed *rostrum*, which does not reach to the extremity of the eyes, whose peduncles are stout and short. *Antennæ* four in number, inserted on two lines, and nearly equal in length: the upper with a peduncle recurved at its base, to receive the eyes, and composed of three cylindroid joints: they are terminated by two rather long filiform stems. Base of the lower antennæ covered by a long lamellar scale, the extremity and internal border of which are ciliated, the terminal stem presenting nothing remarkable. *Mouth* situated at a small distance from the point of the insertion of the lower antennæ, and surrounded, as ordinarily, with a rather stout labrum, a bifid tonguelet, and a pair of *mandibles*, which are armed on their internal border with some pointed teeth, and carry a short and flattened palp, divided into three joints. Two pairs of *jaws* are applied on the mandibles and tonguelet. The first pair offer nothing remarkable. The second are composed of three lamellar joints, the two first of which are bilobated on the internal side: no trace is here to be seen of the great foliaceous appendage which always exists on the external side of these organs in the decapods, and which assists in the mechanism of respiration: their form and structure are absolutely the same as in *Squilla*, *Alima*, &c. The eight pairs of limbs which succeed the jaws, and which correspond both with the jaw-feet and ambulatory feet of the decapod crustaceans, have here all the same form and the same uses: not one of them enters into the composition of the buccal apparatus; but all serve for locomotion. These *feet*, with the exception of the last pair, are long, slender, and bifid, as in *Mysis*. Their basilary joint, stout and short, carries within a long stem, furnished with numerous hairs, and externally a palp or middle branch, composed of two pieces, the last of which is delicate, lamellar, and ciliated on the borders. The length of these natatory feet increases a little from the first to the fifth pair, and then diminishes; those of the eighth and last want an internal stem, and consist only of the external branch or palp. The five first segments of the abdomen support also small natatory feet, formed of a cylindrical peduncle, carrying two elongated and ciliated blades on the borders, the internal of which, shorter than the external, carries in its turn a small cylindrical appendage. The limbs of the sixth and seventh rings of the abdomen become lamellar, constituting a fan-shaped fin, the median narrow and pointed piece of which terminates in three sharp spines; and the lateral ones, equally narrow, are furnished on the borders with long hairs. (M. E.)

Example, *Thysanopoda tricuspida*, the only species known. Length about 15 lines. *Locality.*—Found far at sea, in the Atlantic Ocean, by M. Reynaud.

M. Milne Edwards thinks that the genus *Podopsis**, or *Hammer-headed Shrimp* of Thompson, may belong to this family; but he observes, that it is too imperfectly known to warrant the assignment of precise characters to it. This crustacean, which was found in the Atlantic Ocean, and is phosphorescent, is figured and described in the interesting *Zoological Researches* above quoted.

2nd Tribe. Luciferians.

M. Milne Edwards observes that the genus *Lucifer*, established by Mr. Thompson, is one of the most singular known; and as it does not, without difficulty, admit of arrangement in any of the tribes already established, M. Milne Edwards, though he remarks that its history is still very incomplete, is of opinion that it should be taken as the type of a particular tribe, to which he thinks certain magnified figures of crustaceans in the atlas of Krusenstern's 'Voyage' ought to be referred.

Mr. Thompson states that this singular and extraordinary type, like *Noctiluca*, also described and figured by him in his *Zoological Researches*, conduces to the sparkling appearance of the sea in the tropical regions, and the individual figured by him (see cut) was taken in the Atlantic, in 11° 56′ N. lat. and 32° 55′ W. long.

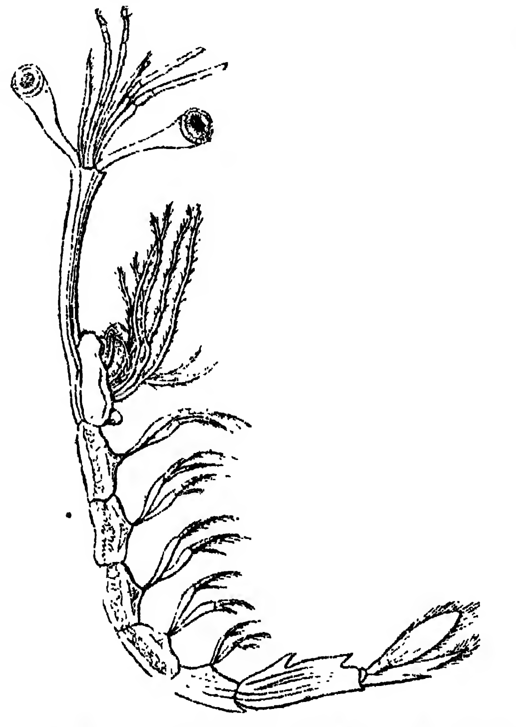
M. Milne Edwards observes, that one of the most remarkable traits of this crustacean is the excessive length of the anterior portion of the head; the extreme brevity of the part of the body occupied by the mouth, and constituting the thorax; and the great development of the abdomen.

Generic Character.—M. Milne Edwards, whose description is more full than that of Mr. Thompson, and who records two species, *Lucifer Reynaudii*, and *L. Typus*, states that the general form of the body is nearly linear. *Eyes* and *Antennæ* carried at the extremity of a long, slender, and cylindrical prolongation, which is much longer than all the rest of the cephalo-thoracic portion of the body, and seems to be formed principally by the antennary ring. A small *carapace* covers the whole of the posterior portion of the cephalo-thorax, and presents nearly the same form as in *Mysis*. The *Eyes* are large, and carried at the extremity of very long peduncles. The first pair of *antennæ* are slender, short, and terminated by a multiarticulate, rudimentary stemlet; the second pair are inserted below, close to the preceding, and are equally slender: near their base is seen a small lamellar appendage, but their mode of termination is unknown. *Mouth* projecting and situated behind the base of the prolongation, which carries the eyes, &c. Here are found *mandibles*, which are strong and toothed, but deprived of a palpiform stem; two pairs of *jaws*, each bearing two blades; two pairs of short and lamellar *jaw-feet*, and one pair of external *jaw-feet*, which are long, pediform, and bent back against the mouth. In succession to these organs may be seen four pairs of long and slender natatory feet, which gradually lessen toward the end, and are furnished with scattered hairs. M. Milne Edwards could find no vestige of a palp or a flagrum at the base of these feet, nor could he perceive any trace of the existence of the last pair of feet, which are here wanting to complete the normal number of the thoracic feet; but he observes that in the figure given by Mr. Thompson, there is at the posterior part of the thorax a tubercle, which is, perhaps, a vestige of those appendages. The *abdomen* is very narrow, and is composed, as ordinarily, of seven rings, but acquires a development entirely abnormal; for each of these segments is at least as long as the whole cephalo-thoracic portion of the body, where the mouth and feet are situated. The five first rings are nearly equal, and each carry a pair of very long false feet, composed of a basilary, cylindrical joint, and of one or two natatory, elongated, multiarticulate, and ciliated blades; in individuals which

* Previously used for a supposed genus of *Conchifera*. [Spondylidæ, vol. xxii, p. 371.]

M. Milne Edwards presumes to be males, the first pair of false feet present towards the middle of their basilary joint a fleshy appendage of odd shape (forme bizarre). The sixth ring is compressed, very long, and toothed below. The abdomen is terminated by a caudal fin, composed, as ordinarily, of five blades disposed in a fan-shape. M. Milne Edwards did not find any vestige of thoracic branchiæ.

Example, *Lucifer Typus*. The same author states that this species differs from *Lucifer Reynaudii* (which was found in the Indian Ocean by M. Reynaud) in the form of the median piece of the caudal fin, which is lamellar, and without any notch below, in the more considerable length of the middle blades, and in the apparent absence of a separation between the carapace and oculiferous prolongation.



Lucifer Typus, Long-headed Shrimp, magnified, and of its natural size. (Thompson.)

The crustaceans numbered 9 and 10 in the atlas of Krusenstern's 'Voyage' are those which, according to M. Milne Edwards, belong to this genus.

II. *Bicuirassed Stomapods*. [PHYLLOSOMA.]

III. *Unicuirassed Stomapods*.

M. Milne Edwards remarks, that the crustaceans of this family are provided with a sufficiently large carapace, but that they nevertheless approach the EDRIOPHTHALMA in the conformation of the thorax, for the greater number of the rings of this middle portion of the body are complete, moveable, and naked, or simply covered by the dorsal buckler without any adhesion to it. The independence of the first segments of the body is carried even farther, he observes, in these crustaceans than in any other, for in the greater part of them, not only the ophthalmic ring, but also the antennular ring remains free, and in some there is a transversal piece at the base of the second pair of antennæ, which seems to be the representative of the lower arch of the third cephalic ring, and not soldered, as ordinarily, with the succeeding ring, of which the carapace is an appendix. Frequently all the thoracic and cephalic rings situated behind this last are equally distinct from each other and more or less moveable, but, with the exception of the four last, they are incomplete above, and represented only by their sternal arch. The abdomen is always very well developed, and is composed of seven moveable segments, the last of which constitutes a very large caudal blade. The *eyes* are stout and convex (*renflés*) towards the end; the first pair of antennæ are inserted below and behind their peduncle, and are composed of a cylindrical peduncle formed of three joints and terminated by three filaments, which are ordinarily multiarticulate. The second pair of antennæ are inserted behind and outside the preceding, and are provided with a great lamellar appendage fixed on a stout and cylindrical joint, at the extremity of the first joint of their peduncle, which also carries in front a filament which is, ordinarily, multiarticulate. The *mouth* is rather distant from the antennæ, and carried on a nearly triangular eminence, the base of which corresponds with the insertion of the prehensile feet. The upper lip is large, projecting, and semicircular. The *mandibles* are directed downwards and terminate by two toothed branches, one of which ascends in the back part of the mouth, towards the stomach; the palpiform stem which carries these organs is small and sometimes null. The lower lip is large and partially covers the extremity of the mandibles. The jaws are very small and applied exactly against the mouth; the first pair terminate by a kind of hook directed inwards, and armed with spines along the internal border of their second joint; there is also a small rudimentary palpiform appendage. The second pair of jaws are lamellar, nearly triangular, and composed of four or five joints placed end to end; nothing resembling a flabelliform appendage is to be seen. The members which belong to the seventh cephalic ring, and which, ordinarily, constitute the anterior *jaw-feet*, do not seem to belong to the buccal apparatus; they are very much elongated and form a pair of slender feet, generally enlarged towards the end, the uses of which are not known. The thoracic limbs of the first pair, which are the analogues of the second jaw-feet of the Decapods and of the anterior feet of the Edriophthalms, are largely developed and constitute great raptorial feet (*ravisseuses*), the last joint of which bends back as a long claw along the internal border of the preceding joint, and forms, after a fashion, a kind of pincer which the animal uses either for defence or the seizure of its prey. The three succeeding pairs of feet are much smaller, and in some sort brought forwards so as, ordinarily, to occupy a curved transversal line, and place themselves between the base of the raptorial feet; they are, in general, applied upon the mouth, and appear to serve only for the prehension of the aliments; they all terminate in a kind of oval hand, armed with a moveable claw, disposed so as to bend itself back against its internal border. These five pairs of limbs carry at their base, on the external side, a membranous vesicular appendage, flattened into the form of a disk and pediculated, which is the analogue of the flagrum, and which, according to some authors, may be a respiratory organ. The three last pairs of thoracic feet are rather distant from each other and directed downwards; they are slender, cylindrical, and nearly always furnished with a styliform appendage which springs at the extremity of their second joint. There are six pairs of abdominal limbs; the five first pairs are formed nearly as in the macrourous decapods, except that their peduncle is much wider, and that, in general, they give insertion to the branchiæ. The appendages of the sixth abdominal ring concur to form the caudal fin; they are directed outwards and terminated by two ciliated blades, between which is a great lamellar prolongation of the basilary joint; the external branch of these false feet is, ordinarily, composed of two joints. There is sometimes on the posterior border of the last segment of the abdomen a pair of moveable spines which may be considered as vestiges of a seventh pair of abdominal limbs. *Branchiæ* ramose, and composed of a great number of small cylinders, carried on stemlets, which, in their turn, spring from a stouter stem (see cut, p. 77); sometimes these organs are completely wanting or do not exist except in the state of vestiges, but, in general, they are highly developed. They are suspended under the abdomen, at the base of the external blade of the five first pairs of false feet, and float freely in the water.

M. Milne Edwards divides this family into two small tribes, *Ericthians* and *Squillians*.

1st Tribe. Ericthians. [ERICHTHUS.]

2nd Tribe. Squillians.

Corresponding with the genus *Squilla* of Fabricius, and the majority of authors, this tribe comprehends, according to M. Milne Edwards, the genera *Squilla* (containing the *Squillæ*, properly so called), *Gonodactylus*, and *Coronis* of Latreille. All these crustaceans have, observes M. Edwards, the greatest resemblance to each other, and the differences upon which these genera are established have not perhaps as much importance as was once thought.

The *Squillians*, says the author last quoted, are, of all the podophthalmous crustaceans, those in which the various constituent rings of the body are the most equally developed and the most independent of each other. With the exception of those which immediately surround the mouth, all these rings are more or less moveable on each other, and the greater part are complete. The *carapace* neither covers the two first rings of the head nor the four last rings of the thorax, and constitutes a horizontal buckler nearly quadrilateral, which is divided longitudinally into three lobes, more or less distinct, by two longitudinal furrows. In front of this buckler is a small triangular and moveable plate, which seems to be a dependence of it, and which covers the antennular ring; its form varies, and as it may be an element in specific differences, M. Milne Edwards terms it the *frontal plate*. The ring which carries the eyes is small, nearly quadrilateral, and moveable on the succeeding segment: the *eyes* are large, short, and convex. The antennular ring is also nearly quadrilateral and moveable, but larger, and gives insertion to the *internal antennæ* by its anterior border on each side of the ophthalmic ring. These appendages are directed forwards; their peduncle is long, slender, and composed of three cylindrical joints, and they terminate in three multiarticulate filaments of moderate length. The *second pair of antennæ* are inserted under the anterior border of the carapace, on each side of the antennular ring, and are formed nearly the same as in the *Erichthians*: the first joint of their peduncle is large and short, and continues itself with an articulation equally stout, which carries at its extremity a great oval blade, analogous to the palp or middle branch of the thoracic limbs, and the basilary scale of the external antenna of the shrimps; the internal branch, which, ordinarily, is greatly developed, remains here slender and so small, that it only seems to be an appendage of the middle branch; it springs from the anterior angle of the common basilary joint, and presents a peduncular portion, composed of two cylindrical joints and of a terminal multiarticulate filament. The *epistome* is very much elongated and constitutes a great projecting mass nearly triangular, the base of which directed backwards forms the upper lip. The *mouth* is situated towards the posterior third of the carapace, and presents on each side a mandible furnished with a small palpiform stem, which is directed forwards on the sides of the epistome: these mandibles are vaulted, and terminate in two diverging branches with dentilated borders, one of which ascends vertically in the interior of the œsophagus. A lower lip, deeply notched, closes the mouth behind, and is applied against the mandibles. The *first pair of jaws* are small, and furnished within with a denticulated lamina on the border, and with a conical lobe bent back upon itself, and terminated by spines: externally these organs carry also a small rudimentary appendage. The *second pair of jaws* are more developed, and cover the whole of the rest of the buccal apparatus; they are lamellar, nearly triangular, and composed of many joints placed end to end. The members, which ordinarily constitute the second pair of jaws, form, as in the preceding tribe, two long, slender, and cylindrical feet, which advance on each side of the head, and bear considerable resemblance to the external jaw-feet of certain macrourous decapods; the vesicular blade fixed to the base of these organs is rather large. The succeeding pair of limbs, which in the decapods constitute the anterior jaw-feet, acquire here a great development, and take the form of raptorial or captatory feet; they are in general bent back thrice upon themselves, and their form calls to mind the anterior feet of the insects of the genus *Mantis* [MANTIDÆ]; the conformation of their claw varies a little, and thus furnishes characters for distinguishing the true *Squillæ* from the *Gonodactyli*. The three succeeding pairs of thoracic limbs, instead of being directed outwards like the raptorial feet, are directed forwards, and applied against the buccal apparatus; they are inserted upon a semicircular line, and the last touch at their base and are brought between the preceding, so that the thoracic ring to which they belong seems at first sight to be apod; their confirmation is essentially the same as in the preceding tribe. The same is the case with the three last pairs of thoracic feet: only they are more developed than in the Erichthians; their appendage is sometimes styliform, sometimes enlarged, and the joint which terminates them is in general lamellar, oval, and ciliated on the border. The rings which carry these three last pairs of feet, and even that which precedes them, resemble almost entirely those of the abdomen, only they descend but little or not at all laterally on the outside of the insertion of the limbs. The *abdomen* is very large, and constitutes a powerful natatory organ: the caudal fin which terminates it is of great size; the basilary joint of the limbs of the penultimate segment is very long, very large, and is prolonged posteriorly into a great pointed blade, which advances between the two terminal branches of those organs; the internal branch consists, as ordinarily, of an oval blade, with ciliated borders; but, as in the preceding tribes, the external branch is composed of two joints placed end to end, of which the first is of some size, and the second lamellar. The false feet of the five first abdominal rings are very large; the basilary joint is quadrilateral, and carries two lamellar branches, the external of which gives attachment by its posterior surface, close to its peduncle, to a great ramose branchia disposed in the form of a plume.

The same author observes that the internal structure of the *Squillians* differs considerably from that of the decapods. The *heart*, instead of being quadrilateral, and enclosed in the middle part of the thorax, has the form of a long vessel, rather enlarged anteriorly, which extends nearly throughout the length of the abdomen as well as of the thorax, and which furnishes laterally in each of the rings which it traverses a pair of arterial branches; by its anterior extremity, this dorsal vessel gives origin to three branches, which seem to be the analogues of the ophthalmic and antennary arteries of the decapods; and, posteriorly it terminates by a small artery which penetrates into the last abdominal segment. The venous sinuses, in which the blood collects before it goes to the branchiæ, are extremely large; the principal cavity belonging to this system occupies the median line of the body, and goes below the intestine and between the lateral muscular masses of the abdomen; its lower wall is formed by a blade of cellular tissue, which encloses in its thickness the ganglionary nervous cord, and which is joined (accolée) to the teguments of the lower surface of the abdomen; on each side it communicates with the intermuscular lacunæ which surround the base of the false feet, and lead to the branchiæ. The peduncle of each of these last organs encloses two longitudinal vessels, the external of which seems to be the afferent canal, and the internal the efferent canal: this last conduit is continued superiorly with an irregular canal, with walls formed only of very fine cellular tissue, and which ascends on the lateral parts of the abdomen, and plunges between the upper longitudinal muscles and the viscera, to reach the upper surface of the heart, where may be seen a double series of branchio-cardiac apertures.

The *stomach* is very large, and advances into the head very far before the œsophagus, which is vertical and extremely short. The solid work (charpente solide) of this organ is much less complicated than in the decapods, and is reduced nearly exclusively to the subpyloric portion, which forms a species of valvule in front of the entrance of the intestine. This last tube is straight, and is surrounded with a cellular and granular mass which appears to be the liver, and which gives origin laterally to small prolongations which insinuate themselves between the muscles of the base of the feet.

This organ, according to M. Duvernoy, is a nervous sinus; but M. Milne Edwards thinks that the appearance which gave rise to this opinion depends on alterations which take place in the *Squillæ* after death, for the results of the dissection of several fresh individuals appeared to the latter incompatible with this new determination proposed by the scientific professor of Strassburg. (See *Compte Rendu*, 8th May, 1837.)

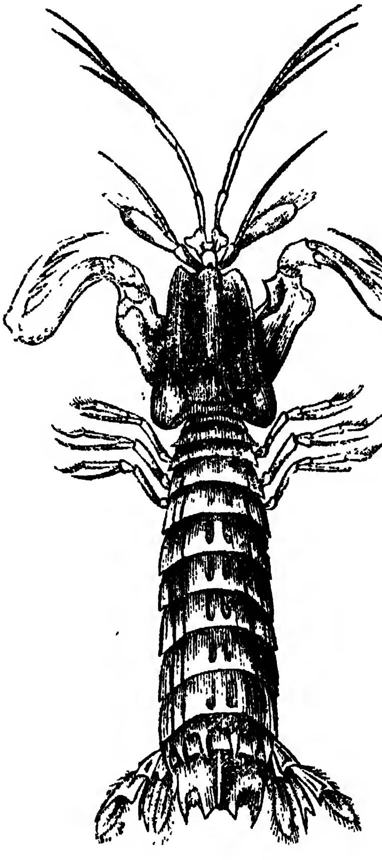
The organs of generation are situated above the digestive apparatus. In the male there issues from the base of each of the posterior feet a long slender cylindrical and white tube, which, in making a great number of circumvolutions, is directed backwards on the sides of the intestine, and terminates towards the anterior third of the abdomen in a whitish and lobulated mass, which is the analogue of the testicle, and which extends to the anus. The penes have the form of two horny tubes, the length of which is often very considerable. The ovary occupies the same place as the testicle, but is larger.

The nervous system presents nearly the same disposition as in the greater portion of the macrourous decapods; in the abdomen the ganglions are well developed, and the cords double; it is the same with the thoracic ganglions of the three last pairs, but all those of the anterior portion of the thorax are united in a single oval mass.

Genera.—*Squilla; Gonodactylus; Coronis.*

Squilla. (Rondeletius.)

M. Milne Edwards points out that the true *Squillæ* are probably more carnivorous than the other crustaceans of this tribe, for they are furnished with much more powerful offensive arms. The claw which terminates their raptorial feet has a falcular form, the sharp edge of which is provided with long pointed teeth, and can be received into a groove of the corresponding border of the hand, which is equally compressed, and in general armed with spines on its prehensile border. The three last pairs of thoracic feet carry a slender, cylindrical, and elongated appendage, which represents the palp. The body is in general more slender and narrowed behind the carapace than in the other *Squillians*.



Squilla, seen from above.

Locality, Habits, &c.—*Squillæ* show themselves in the British Channel; but the species which are numerous are abundant only in the seas of warm regions; they keep in general at a distance from the coast, and at considerable depths. Their abdominal false feet are continually in motion, and they swim with great swiftness, striking the water with their powerful tail.

M. Milne Edwards divides the true *Squillæ* into two subgenera:—1, *Squilles Fines-tailles;* and, 2, *Squilles Trapues.*

1. Slender Squillæ.

The species arranged by M. Milne Edwards under this subgenus are remarkable for the narrowing of the posterior portion of their thorax and the gradual enlargement of the abdomen. The carapace, enlarged backwards, hardly reaches the anterior edge of the thoracic ring which precedes the three last segments provided with feet. The rostral plate hardly ever covers the ophthalmic ring. The last segment of the abdomen is never furnished with moveable marginal spines. The subgenus is divided by M. Milne Edwards into the following sections:—

a. Species whose abdomen presents above neither crests nor large tubercles, and has its last segment twice and a half as wide as it is long; rounded and hardly dentilated.

Example, *Squilla maculata.* Length from ten to twelve inches, and rather more. Colour yellowish; with three bluish bands on the carapace and a similar transversal band on the articulation of the rings of the abdomen.

Locality.—The Asiatic Seas.

β. Species whose abdomen presents above many longitudinal crests, or large elongated tubercles, and has its last segment in general nearly as long as it is wide.

* *Rostral plate not covering the ophthalmic ring.*

Example, *Squilla Mantis.* Length six or seven inches and upwards. Colour very pale yellowish grey.

Locality.—The Mediterranean.

* * *Rostral plate entirely hiding the ophthalmic ring.*

Example, *Squilla Ferussaci.* Length about four inches. Moveable claw armed with three teeth only. Colour purplish washed with greenish.

Locality.—The coasts of Sicily.

2. *Stout Squillæ.*

This subgenus has the body very convex, all of a size, without any notable narrowing at the back part of the carapace. The posterior portion of the thorax is as wide as the abdomen, and the carapace reaches ordinarily to the antepenultimate thoracic ring. The rostral plate covers the ophthalmic ring entirely. The two posterior teeth of the last ring of the abdomen carry each at their extremity a moveable spine.

Example, *Squilla stilifera.* Last segment of the abdomen furnished above with seven delicate crests; two moveable spines inserted near the median line. Length about three inches.

Locality.—The Isle of France.

Gonodactylus. (Latreille.)

This genus bears a strong resemblance to the *Stout Squillæ* (Squilles Trapues). The principal distinction lies in the mode of conformation of the raptorial feet. The last joint of these organs, in lieu of having the form of the claw lamellar and strongly dentated, is straight, styliform, more or less convex at its base, and presents at most only vestiges of teeth on its prehensile border, which is enlarged. In general the convexity of the basilary portion is very considerable, and suffices to distinguish these crustaceans at the first glance.

* *Rostral plate armed on the median line with a long spiniform tooth.*

Example, *Gonodactylus Chiragra.* Length about three inches and a half.

Localities.—Probably all the seas of warm climates; Mediterranean, American coasts, Seychelles Islands, Trincomalee, and Tongataboo.

* * *Rostral plate rounded and nearly pointed in front.*

Example, *Gonodactylus Scyllarus.* Length about four inches and a half.

Localities.—Indian Seas and the coasts of the Isle of France.

Coronis. (Latreille.)

This form does not appear to M. Milne Edwards to differ sufficiently from the *Squillæ*, properly so called, to authorize its generic separation; but as he had not observed it himself, he continues to retain it as a genus. The following is Latreille's character:—

Lateral and posterior appendage of the third joint of the six last feet (the adactylous and thoracic) in form of a membranous blade or battledore (palette), which is nearly orbicular and a little bordered (rebordée).

Example, *Coronis Scolopendra.* (See Guerin, *Iconographie*, pl. 24, fig. 2.)

STOMATE'LLA. [HALIOTIDÆ, vol. xii., p. 16.]

STOMATES (from the Greek στόμα, an 'opening,' or 'mouth'), in Botany, are small longitudinal openings occurring in the epidermis of plants, and usually bounded by two or more lunate or kidney-shaped vesicles. The epidermis of plants has been described by Brongniart and others as consisting of three parts, which may be easily demonstrated by a lengthened maceration. The outermost of these consists of an 'extremely delicate homogeneous pellicle,' which does not present any decided marks of organization, and is perforated in places where the stomates exist. The second part consists of a single layer, sometimes of more than one, of flattened vesicles of cellular tissue. These vesicles are very small, and of various figures, but the most frequent form is the hexagonal. The third

part of the epidermis is the stomates, which are placed under the above-mentioned pellicle and on the same plane with the layer of flattened vesicles.

The first botanist who observed the existence of stomates was Grew, who, in his 'Anatomy of Plants,' published in London, in 1682, gave an imperfect representation of these organs, and stated that they existed on several parts of plants, but he gave them no especial name. Malpighi afterwards described their existence in the epidermis of Marchantiaceæ, where they are very large, but entirely overlooked them in the higher plants. Guettard was the next writer who noticed them, and, believing them to perform the office of glands, called them *glandes miliaires* (glandulæ miliares). Saussure also thought them glandular bodies, and called them cortical glands. Hedwig and Gleichen were the first to give accurate drawings of them; and from that time their existence excited general attention, but they received a variety of designations. Hedwig called them *spiracula* and *pori exhalantes*; De Candolle, *pores corticaux*; Krocker, *rimæ annulatæ*; Mirbel, *pores allongés*. Sprengel and other German writers designate them as Spaltöffnungen; Rudolphi called them pores of the epidermis; Link proposed the name stomata, which has since been adopted by De Candolle, Brongniart, and Mirbel in France, and Lindley and Henslow in England. Link has however since proposed the name of Hautdrüsen (skin glands), and this term is adopted by Meyen and later German botanists.

The structure of the stomates is best seen in the monocotyledonous plants, in which they generally occur of a larger size. They are quite imperceptible to the naked eye, but may be discovered by a lens of low power. In general they will be found to consist of two kidney-shaped bodies, which are merely cells of cellular tissue filled with a green matter, and from this circumstance contrast with the transparent cuticle in which they are placed. The kidney-shaped bodies lie with their incurved edges presented to each other, and their extremities unite with each other so that they leave between them a little oval chink or opening. This opening communicates with the parenchyma of the leaf or other organ underneath the cuticle, and at this point the cellular tissue is loose, and frequently a large cavity is observed, into which the stomate opens. Nees von Esenbeck, Brown, and others denied at first that the space between the kidney bodies was an opening, but the observation of later writers seems to have proved this point. (Lindley, *Introd. Bot.*, p. 52.) This difference among observers may perhaps be explained by the fact that the kidney-shaped bodies have a power of contracting and dilating, and thus closing or opening the space between them. This was first observed by Comparetti, and has since been confirmed by other writers.

The stomates are not all composed of two cells; those of Marchantia, according to Mirbel, are composed of four or five cells, which are arranged circularly, forming an upper outer rim of the stomate. Sometimes additional cells are found above these, but they differ little, except in their arrangement, from the cells of the tissue by which they are surrounded. This is one of the simplest forms of stomate. In *Nerium oleander* the stomates consist of cavities in the cuticle, which are filled up with little hairs. Dr. Lindley has described in Nepenthes two sorts of stomates, 'the one oblong, semitransparent, and almost colourless, with numerous pellucid globules in the cavity of the cells; the other roundish, much more opaque, and coloured red.' Although the form of the stomates is most frequently elliptical, they are sometimes quite spherical, as in *Oncidium altissimum*, and Link has noticed them of a quadrangular form in *Yucca gloriosa*.

The stomates are mostly arranged irregularly upon the surface of the epidermis, occupying generally about equal distances from each other. There are however some remarkable exceptions. In the grasses, for instance, and some other monocotyledonous plants, the stomates are arranged in regular rows, which run parallel with the bundles of woody tissue which enter into the composition of the leaf. In *Phormium tenax* and in Pinus the stomates are also arranged in a longitudinal series. In *Begonia spathulata* the stomates on the under surface of the leaves are collected together in the form of little rosettes. The same is seen in *Crassula cordata* and *arborescens*.

Stomates are found on plants whenever there is a distinct epidermis, and they exist on nearly all the parts of a plant exposed to the light. In the lower cryptogamic plants, as mosses, fungi, lichens, and algæ, they have never been found. Plants growing in the dark do not possess them, nor are they present on roots or the ribs of leaves. They are found on the bark of herbs and trees, but in the latter only whilst the bark is herbaceous. In those plants which live under water, as the Zostera, Ceratophyllum, and Potamogeton, they are not found. Those parts of the leaves of some plants which are concealed under the ground, as in the onion, &c., have no stomates. All the parasitical plants which have not a green colour, as the Orobanchaceæ, Lathrea, and Monotropa, are destitute of stomates, whilst those which are green, as the Loranthus, have abundance. They are only rarely found upon the filaments of the stamens, the anthers, or the styles. With the exception of Canna, they have not been found on the seeds of plants, nor are they present on fruits, except such as are membranous.

Stomates are not always present on both surfaces of the leaves. They are however much more frequently absent on the upper than on the under surface of the leaf.

The number of stomates contained in a given surface varies very much in different species and families of plants. Many observers have occupied themselves in counting them, and the following table gives the result of some of the observations of Sprengel, Krocker, Thomson, and Lindley on this point:—

Names of Plants.		Number of Stomates in a square inch.	
		Under side.	Upper side
Lilium album . .	Sprengel	17,280	3,556
——— bulbiferum .	Hedwig	83,000	not count
Tradescantia discolor .	Sprengel	9,000	
Alisma Plantago .	Thomson	16,000	12,000
Andromeda speciosa .	..	32,000	none
Hydrangea quercifolia	..	160,000	none
Sempervivum tectorum	..	6,000	10,710
Rumex acetosa .	..	20,000	11,088
Viscum album . .	..	200	200
Prunus Laurocerasus	Lindley	90,000	none
Crinum amabile .	..	20,000	20,000
Stapelia (stem) . .	..	..	15,000
Cactus (stem) . .	..	..	15,000
Aloe (leaf) . .	..	20,000	25,000
Yucca . . .	..	40,000	40,000
Pinus halepensis .	Krocker	2,700	
—— Abies . .	..	3,600	
Aloe nigricans . .	..	7,200	
Citrus aurantium .	..	409,824	
Solanum sanctum .	..	448,704	

Meyen, who records Krocker's calculations, does not state on which side of the leaf he observed the stomates.

Brown is of opinion that the figure, number, and size of stomates might often be made use of to indicate the affinities of genera and natural families of plants, and has proved that this is the case in Proteaceæ. Schleiden also, in a recent paper, has pointed out the relations and differences of these organs in Cactaceæ, Coniferæ, Piperaceæ, and other orders.

The different names that have been given to the stomates by various writers will at once indicate the differences of opinion that have existed with regard to their functions. It was an early opinion that they were excretory glands, and that through their agency the bloom that exists on the leaves, &c. of many plants was formed. But this exists, as on the surface of plums, where there are no stomates. Link and Meyen still maintain that they are glands. The latter observes that the structure of the cells of the stomates is precisely similar to that of many of the glands of plants, and that supposing the stomates were only looked upon as organs by which exhalation is effected, yet that process is one of excretion rather than of simple evaporation. It is for this reason he still calls them Hautdrüsen (skin-glands), and looks upon them as excretory organs.

Bonnet found that leaves when flagging were restored by placing one of their surfaces in water, and hence he concluded that one of the functions of the stomates was to absorb moisture from the atmosphere, but the hygroscopicity of vegetable tissue would account for this absorption,

and would effect it when necessary without having recourse to the supposition that a special organ was provided for it.

That they are organs by which the process of exhalation is carried on as a vital process, there is much reason to suppose. They exist in the greatest abundance in those parts of plants in which this operation is going on, they are also most abundant in membranous leaves, which are known to exhale most, and are deficient in succulent leaves, in which there is little exhalation. It was long ago observed by Comparetti, that the mouths of the stomates were open by day and closed at night, and this is quite in accordance with what we know of the action of light on the function of exhalation. It is more active in the day, and the mouths of the stomates are opened to allow of the exit of the vapour. Another argument in favour of this view is derived from the non-existence of stomates in those families of plants in which no proper transpiration takes place.

For further information consult Meyen, *Pflanzen Physiologie*; Lindley, *Int. Bot.*; De Candolle, *Organographie Végétale*; Brongniart, *Ann. des Sc. Nat.*, 1834.

STOMA'TIA. [HALIOTIDÆ, vol. xii., p. 17.]

STO'MIAS, a genus of fishes of the Pike tribe (family *Esocidæ*), distinguished by the muzzle being very short, the mouth very deeply cleft, the opercula reduced to small membranous laminæ; the maxillaries fixed to the cheeks; the intermaxillary, palatine, and maxillary bones are rather sparingly furnished with teeth, and these are long and hooked, and similar teeth are observable on the tongue. The body is elongated, the ventral fins are placed very far back, and the dorsal fin is placed opposite the anal fin, on the hinder extremity of the body.

Only two species of this genus are known, both of which are inhabitants of the Mediterranean. One, the *Stomias barbatus*, has been so called on account of its having a long barbule on the chin. Both species are of a black colour, but have numerous rows of small silver spots on the abdomen.

The genus *Chauliodus*, Schn., appears to be closely allied to the present fishes, presenting much resemblance in the structure of the head and jaws, which are furnished, in front, each with two teeth which cross when the jaws are closed. The dorsal fin is placed opposite the interval of the pectoral and ventral fins, which are not placed so far back as in *Stomias*. The first ray of the dorsal is produced into a filament. One species only is known, the *Esox stomias* of Schneider, a fish found at Gibraltar (and apparently nowhere else), and which attains the length of about fifteen or eighteen inches, and is of a deep green colour.

STONE, METEORIC. [AEROLITES.]

STONE. [CALCULUS.]

STONE. [STAFFORDSHIRE.]

STONE, EDMUND, a mathematician of North Britain. He was of humble origin, having been the son of a gardener in the service of the duke of Argyle, and he was born near the end of the seventeenth century, probably on one of the duke's estates. A servant of the family taught him, when a boy, to read; and with no other guide than his own genius, he at length became learned in the higher branches of mathematical science.

The duke, happening accidentally to become acquainted with the extent of his scientific acquisitions, took an opportunity of drawing from him an account of the steps by which he had attained them, and learned with surprise that, from a desire to understand the use of a rule and compasses, and how to make computations relative to the art of building, the youth from books only had taught himself arithmetic and geometry, together with as much of Latin and French as enabled him to read scientific works in those languages.

It will be readily imagined that the young man was not left in his then obscure situation: in fact the duke, his master, generously gave him an employment which allowed him to have sufficient leisure for his studies; and he continued to cultivate the mathematical sciences to the end of his life. He was elected a fellow of the Royal Society in 1725, and there is inserted in the 'Philosophical Transactions' (vol. 41) a paper by him in which is an account of two lines of the third order, which are not mentioned by Sir I. Newton or by Mr. Stirling.

It is not known from what circumstance Mr. Stone lost the support of the noble family which had patronised him; but it appears that in the latter part of his life he subsisted by giving lessons in mathematics, and that he died in poverty in 1768.

Mr. Stone published, in 1723, a translation of Bion's 'Treatise on Mathematical Instruments;' in 1726, a 'Mathematical Dictionary,' in 1 vol. 8vo.; and in 1730 a translation of the Marquis de l'Hôpital's 'Analyse des Infiniment Petits,' together with a treatise by himself on the 'Method of Fluents, or the Inverse Method of Fluxions.' This work has been criticised by John Bernoulli; but the mistakes which occur in it are candidly ascribed to the circumstances under which it was written. In the following year Stone published 'The Elements of Euclid,' in 2 vols. 8vo., and in 1735 a translation, from the Latin, of Dr. Barrow's 'Geometrical Lectures.'

STONECHATS. [WARBLERS.]

STONEHENGE, an assemblage of upright, horizontal, and prostrate stones on Salisbury Plain, England; generally supposed to be the remains of an antient Druidical temple. The name is probably derived from the Saxon, *stan*, stone, and *heng*, or *hang*, to hang or support. By the Welsh antiquaries it has been called *choir-gaur*, *chorea-gigantum*, or, according to Stukeley, *chorus magnus*, the great choir or circle.

Stonehenge, with the far-famed pyramids of Egypt, and other works of the same class, may be considered as the oldest monuments of man's labour. Being anterior to all written evidence, their history is entirely unknown, and they have been the subjects of much unprofitable speculation, some of which however will require a short notice.

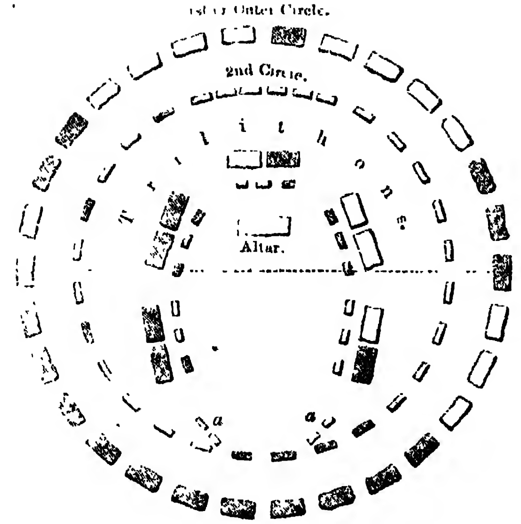
Stonehenge is situated about two miles due west of the town of Amesbury, and seven north of Salisbury, in Wiltshire. From its singular character and peculiar situation, which is easy of access, it has attracted more attention than any other relic of antiquity in Great Britain. Viewed at a distance it appears a trifling object; for its real magnitude appears diminished in the extensive plain or open country which surrounds it; and even on a near examination it often fails to satisfy expectation.

In various parts of the world there are circles of upright stones, some of which consist of a single circle, and others of many circles: but Stonehenge is of a peculiar character, and is, we believe, wholly unlike any other antient monument. Many of the stones have been squared, or hewn by art, and the horizontal stones of the outer circle are carefully attached by mortices to the uprights, which have tenons: whereas nearly all other examples of what are generally called Druidical circles are composed of rough unhewn upright stones, without imposts. The accompanying diagrams will give an exact notion of the form, arrangement, position, and general design of the whole structure, in its original as well as in its present state.

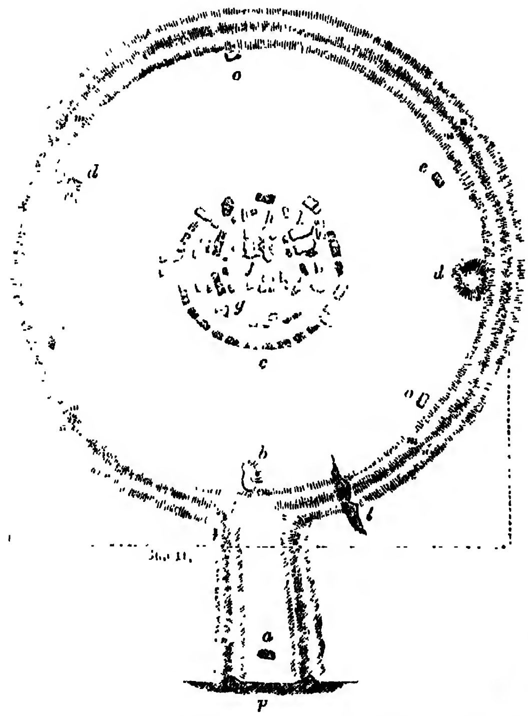
The stones are surrounded by a circular vallum, or bank of earth, within a ditch or foss. Withinside this bank are three stones, two of which are in an upright position, and the other is prostrate. It has been conjectured by Browne, with some probability, that those originally formed part of a circle. In the centre of the enclosed space is what is usually called the temple itself, which comprised originally an outer circle of thirty upright stones, at nearly equal distances apart, sustaining as many stones in a horizontal position, forming a continuous impost. Each of the upright stones had two tenons or projections on the top, which were adapted to fit into and fill up two mortices or hollows in each superincumbent slab. Within this was another, or second circle, consisting of about the same number of perpendicular stones, of much smaller size, and without imposts. This circle enclosed an elliptical arrangement of large and small stones: the former, which were divided into groups of three stones each, are called trilithons by Dr. Stukeley and subsequent writers. There were five trilithons, each of which consisted of two upright stones, and an impost, covering or extending to the extreme edges of the standing stones. Before each trilithon stood three small upright stones; and in the central space, or adytum, of the temple (in front of the principal trilithon) was a large flat stone, called the altar. This description will be readily understood by an examination of the accompanying cuts.

The plan No. 1 shows the original design of the main part of the temple: the stones which have fallen, or are entirely removed, are marked in outline, whilst the stones remaining in their original positions are shaded. The plan No. 2 shows, more minutely, the present dilapidated state of the edifice, together with the vallum and fosse, and other exterior works.

No. 1.



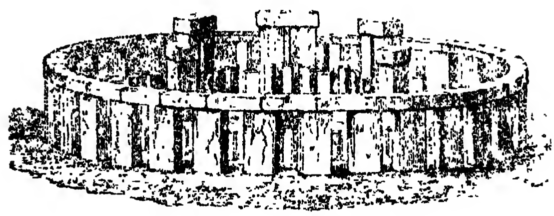
No. 2.



Ground-plan of the whole work in its present state, showing the approach or avenue from the north east, with one stone still standing, *a*, at the distance of about one hundred feet from the ditch; *b*, fallen stone in the ditch; *c* supposed entrance through the exterior circle, in a line with the avenue, and near the middle of the temple. *d*, *d*, two cavities or hollows in the ground; *e*, *e*, two stones, adjoining the surrounding bank; *f*, a flat stone, usually called the altar; *g*, a small impost stone with two mortices. The small size of this stone, as compared with the imposts of the outer circle and those of the trilithons, has caused much conjecture and speculation among the writers on this monument, as it could not have belonged to or formed any part of those portions of the structure. Some contend that it was part of a small trilithon in that situation, and that there was another of similar proportion on the opposite side, or on the right hand of the entrance (See Plan No 1, *a*, *a*) : *h*, the tallest stone in the place, and forming part of the chief trilithon, or most prominent part of the structure; its corresponding stone, as well as the impost, have fallen: *i*, *i*, two standing and nearly perfect trilithons: *k*, a fallen trilithon, its three stones perfect, showing the full forms, proportions, and junction of the uprights and the impost; these fell in the year 1797: *l*, section through bank and ditch, marked *m*, *n*; *p*, section of banks on each side of the avenue: *o*, *o*, sites of two stones near the surrounding bank.

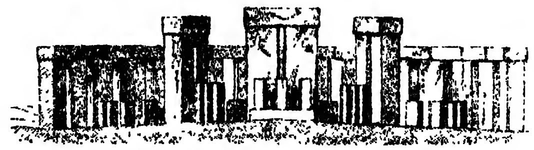
With respect to the two principal circles, the restorations given by Stukeley, Inigo Jones, Wood, and Smith, vary in no essential particulars; but as regards the number and arrangement of the trilithons, and the small upright stones before them, they differ materially from each other. Jones, for instance, made the number of trilithons *six*. The plan No. 1 (from Stukeley) seems fully justified by the existing remains, as shown in plan No. 2, whilst the discordant opinions on this point are easily accounted for by the fact that the central portion of the temple is comparatively in a much more ruinous condition than the two principal circles.

No. 3.



Stonehenge.—Perspective Elevation.

No. 4.



Stonehenge: section 1 to 2 (ground-plan, No. 1), 105 feet.

The plans (1 and 2), perspective view (3), and section (4), render it unnecessary to give a description of the present state of Stonehenge. The dimensions of the stones, and the space occupied by the structure, as nearly as they have been ascertained, are—

Diameter of the space enclosed within the vallum or bank . . .	300 feet.
Height of vallum . .	15 feet.
Diameter of the outer circle	100 feet.
Do. of the second circle .	83 feet.
Height of the stones of outer circle	14 (*sides* 7 feet by 3).
Do. of trilithons .	16 ft. 3 in., 17 ft. 2 in., 21 ft. 6 in.
Do. of one of the small stones before the same . .	7 ft. 6 in.

The stones of the outer circle, the trilithons, the stones in the avenue, and adjoining the vallum, are, according to Dr. Townson, in 'Tracts and Observations on Natural History,' &c., 'a pure, fine-grained, compact sand-tone, differing only a little in their colour, some being white, and others inclining to yellow.' They precisely resemble the grey-wethers and numerous other detached masses which lie on the surface of the downs in the vicinity of Avebury and Marlborough. The stones of the second circle, and the row within the trilithons, consist of 'a fine-grained grünstein,' interspersed with black hornblende, felspar, quartz, and chlorite, excepting four in the circle, one of which is a siliceous schist, another is an argillaceous schist, and the others are hornstone, with small specks of felspar and pyrites. The slab or altar-stone is different from all these, being a kind of 'grey cos, a very fine-grained calcareous sandstone,' which strikes fire with steel, and contains some minute spangles of silver mica.

The surrounding plain is covered with a profusion of barrows and earth-works, perhaps unparalleled in any spot of similar extent in England, and probably in the world. Many of the barrows were opened by Sir Richard Hoare and his indefatigable coadjutor Mr. Cunnington, and were found to contain, in some instances, cists or chests, filled with burnt bones, and in others entire skeletons, with various relics of British and Roman art. Some other objects besides the barrows demand our notice. The principal of these are the avenue and the cursus, the former of which has been previously noticed. It is a narrow strip of raised ground, bounded on each side by a slight bank of earth, and extending in a straight line from the entrance, through the vallum of the structure on the north-east, to the distance of 594 yards, at which spot it divides into two branches, one of which continues southward, and is seen between two rows of barrows: while the other proceeds northward, and approaches within a few yards of the cursus. The cursus is a very curious and interesting appendage to Stonehenge, if it can be properly so considered. It is a flat tract of land, bounded by two parallel banks and ditches, and is situated about half a mile north-east of Stonehenge: it measures one mile five furlongs and 176 yards in length, and 110 yards in breadth. Its direction is from east to west; and at the former extremity is a mound of earth resembling a long barrow, which stretches entirely across it. The western extremity is destitute of any mound like that at the eastern end, but there

are two barrows irregularly placed near this end within the area of the cursus, a part of which appears also to be cut off by a slight bank. The original purpose of this bank is difficult to determine, for we can scarcely suppose that if the chariots started from the east end, they would be driven *over* this bank, to the termination of the course at this end. We should therefore be inclined to think that it had been raised at a later period, for some object distinct from racing, if there were not another similar bank thrown across a second and smaller cursus, which is situated at the distance of nearly a mile from the larger one. From the near resemblance of the above work to the genuine circus of the Romans, it is reasonable to suppose that, if not formed by the Romans, it was made in imitation of their chariot-course, and by a people familiar with their manners and customs. Hoare's 'Antient Wiltshire' contains a very interesting map, showing the surface of the plain around Stonehenge to the extent of about five miles from east to west by three miles from north to south. Within that area are two large encampments, two cursuses, other embankments supposed to mark British villages, and at least three hundred barrows or tumuli of various sizes and shapes. Hence it may be reasonably inferred that Stonehenge was a place of great importance in former ages.

The earliest published notice of Stonehenge occurs in the writings of Nennius, who lived in the ninth century. He narrates the particulars of the murder of four hundred and sixty British nobles at a conference between King Vortigern and Hengist, in the latter part of the fifth century, at or near the spot on which Stonehenge is situated; and attributes the erection of the monument to the surviving Britons, who thus endeavoured to perpetuate the memory of that tragical event.

The historical 'Triads of the Welsh Bards' refer its origin to the same cause, and relate that it was constructed by Merlin, after the death of King Vortigern. This likewise is the account of Walter Mapes [GEOFFREY OF MONMOUTH], who is very circumstantial in his narrative.

Geoffroy of Monmouth, who wrote in the 12th century, gives a similar account of its origin, with the addition of a legend, which is repeated by most subsequent writers. He states that Merlin employed supernatural agency to remove the stones from Kildare in Ireland and place them upright on Salisbury Plain; and he adds that they had been in the first instance conveyed to Ireland from Africa. The same story appears in Giraldus Cambrensis (1187), who mentions a similar monument which he had seen on the plains of Kildare.

Henry of Huntingdon, who also wrote in the twelfth century, discredits the story of Merlin; and says that no one can devise by what means or for what purpose such a work could have been raised. Neither Gildas, Bede, William of Malmsbury, Hovedon, Ingulphus, Matthew Paris, nor Florence of Worcester, have any notice of this remarkable monument; a circumstance which Henry of Huntingdon attributes to their inability to give any account of its origin or use.

Polydore Virgil (1534) says that it was raised by the Britons to the memory of Aurelius Ambrosius. Camden, who wrote in 1586, gives no opinion on its origin or purpose. His description and representation are so very erroneous, that it is doubtful if he ever visited the place. John Aubrey, in a manuscript referred to by Bishop Gisbon, and Sir Richard Hoare, attribute its origin to the Britons prior to the Roman invasion.

Such is the scanty information which our old writers contain about this curious monument of antient times. Modern writers on Stonehenge, rejecting all historical evidence, have raised their theories on purely speculative foundations. Inigo Jones, in his essay on Stonehenge, undertaken at the desire of King James I., and which was published in one small folio volume, by his son-in-law John Webb, A.D. 1655, endeavours to show that Stonehenge was a temple of the Romans, of the Tuscan order, dedicated to Cœlus; but he has committed palpable errors in his restorations, to say nothing of the absurdity of his general assertion. The next essay was written about 1660, and published anonymously, in Langtoft's 'Chronicle,' called 'A Fool's Bolt soon shot at Stonage.' The writer considers it to have been a British temple, commemorative of a victory gained by the Cangi of Somersetshire, over King Divitiacus and his Belgæ. In 1663 Dr. Charleton published his 'Reflections on Stonehenge,' in which he contends that it was erected by the Danes, in the time of King Alfred, as a place for the crowning of their kings. Charleton's 'Reflections' called forth an essay of 228 folio pages, in support of Inigo Jones, by his editor John Webb, published in 1664: this essay is of no value. In 1676 appeared a volume by Aylett Sammes, who remarks, 'Why may not these giants (alluding to the title of *Chorea Gigantum* given to this monument) be the Phœnicians; and the art of erecting these stones, instead of the stones themselves, brought from the furthermost parts of Africa, the known habitations of the Phœnicians?' To this sage question one may answer, why may not the stones have come from the moon, and dropped down in their present position?

Bishop Gibson, in his edition of Camden's 'Britannia,' 1694, after opposing the theories of Jones and Charleton, concludes, 'One need make no scruple to affirm that Stonehenge is a British monument; since it does not appear that any other nation had so much footing in this kingdom as to be authors of such a rude and yet magnificent pile.' The bishop thinks that some part of this temple may have been erected subsequently to the Roman invasion; a conclusion which seems to be very probable. With reference to its modern name, Gibson refers to a Saxon manuscript of good authority, printed by Dugdale in the 'Monasticon,' in which it is called *Stanhengist*, proving its traditional connection, at an early period, with Hengist. In 1720 J. G. Keysler, a learned German antiquary, published, at Hanover, 'An Explication of the *Anglo-Saxon* Monument of Antiquity on Salisbury Plain, called Stonehenge.'

In 1740 Dr. Stukeley published a folio volume, entitled 'Stonehenge, a Temple restored to the British Druids:' he attributes the work to the British Druids. The plates which accompany his volume are good; and Stukeley's restorations are valuable; but a huge portion of his essay is occupied with fanciful and irrelevant speculation.

J. Wood, an architect of Bath, published a series of elaborate plans of this structure, in 8vo., 1747. It is his opinion that it was a temple erected by the British Druids, about 100 years before the Christian æra.

The Rev. W. Cooke, in a treatise entitled 'An Enquiry into the Patriarchal and Druidical Religion, Temples, &c.,' 1755, supposes Stonehenge to have been held sacred by the Druids, and appropriated to the meetings of great assemblies, on civil as well as religious occasions; for which, he adds, 'the world does not afford a nobler spot.'

Dr. Smith's work on Stonehenge, called 'Choir Gaur,' 1771, gives a minute description of the structure, with a notice of most of the theories to which we have referred. He considers it to have been of Druidical origin, and that it was a 'great orrery,' erected as well for the purposes of astronomical observation as for religious ceremonials.

Edward King, in his 'Munimenta Antiqua,' devotes much space and applies great learning to the consideration of antient stone monuments. He conjectures that Stonehenge was constructed in the latest ages of Druidism, when that religion was struggling against Christianity.

Mr. Davies, the learned author of 'Celtic Researches,' 1804, and the 'Mythology of the Druids,' 1809, has discussed the question respecting the origin and use of Stonehenge perhaps with more research than any previous writer. He supposes that this structure and Silbury Hill are two of the three works alluded to in a Welsh Triad as constituting the greatest labours of the island of Britain; *i.e.*, 'lifting the stone of Ketti,' 'building the work of Emrys,' and 'piling the Mount of the Assemblies.' That Stonehenge is really a Druidical structure, the same learned writer remarks, 'is evident, from the language in which it was described, and the great veneration in which it was held, by the primitive bards, those immediate descendants and avowed disciples of the British Druids.' 'It was not exclusively dedicated to the Sun, the Moon, Saturn, or any other individual object of superstition; but it was a kind of Pantheon, in which all the Arkite and Sabian divinities of British theology were supposed to have been present.' As to its date, he remarks that 'it was a monument of venerable antiquity in the days of Hengist, and that its peculiar sanctity influenced the selection of the spot for the place of conference between the British and Saxon princes. Mr. Davies further cites a passage in Diodorus Siculus, who quotes Hecatæus, describing a round temple in Britain, dedicated to Apollo, which he concludes to have been most likely Stonehenge. (Diod., ii., 47.) Sir R. Hoare has entered more fully into this passage (*Antient Wiltshire*, i. 155),

The Rev. Jas. Ingram, in his 'Inaugural Lecture on the Utility of the Saxon Literature' (1808), considers Stonehenge to have been intended for a heathen burial-place, and the cursus adjoining as the hippodrome on which the goods of the deceased were run for at the time of the burial. This opinion is entitled to some consideration, from the vast number of barrows and other earth-works which abound in this part of the plain.

The late Mr. Cunnington, in Sir R. C. Hoare's 'History of Antient Wiltshire,' folio. 1812, observing the difference in quality and size between the stones of the exterior and interior circles, supposes that Stonehenge was erected at different times. He imagines that the larger stones, with their imposts, constituted the old or original work; and that the small stones of the second circle, and those of the inner range, were raised at a later time, as 'they add nothing to the grandeur of the temple.' But this opinion is not warranted by any example among the numerous Druidical circles of Great Britain; on the contrary, it seems more consistent to conclude that the second circle, of small, rough, unhewn stones, with another circle immediately within the ditch, and some other members now destroyed, formed the original or pristine temple, and that the larger hewn stones with imposts were afterwards added. Many arguments might be alleged in support of this opinion, and also to prove that the great circle of upright chiselled stones, with their imposts, and the third row of trilithons, were posterior to the former, raised by another class of people, and executed at a time when their principles and arts had been considerably changed. At the same time it is conjectured that an avenue of stones was raised, extending from the temple towards the cursus to the north-east, and also that those places for races and other sports were formed at a time when the inhabitants of Britain had intercourse with the Romans.

The 'Topographical Account, &c. of Wiltshire,' by J. Britton, forming the fifteenth volume of the 'Beauties of England and Wales,' 1814, contains an accurate description of Stonehenge and of other antiquities in its immediate neighbourhood.

In 1823 H. Browne published 'An Illustration of Stonehenge and Abury,' in which he endeavoured to show that both of those monuments were antediluvian, and even that the latter was formed under the direction of Adam. He ascribes the present dilapidated condition of Stonehenge to the operation of the general Deluge: 'for,' he adds, 'to suppose it to be the work of any people since the Flood, is absolutely monstrous.'

Godfrey Higgins, in a large 4to. volume, 1829, entitled 'The Celtic Druids: or an attempt to show that the Druids were the Priests of Oriental Colonies, who emigrated from India,' has given an elaborate account, with plates, of Stonehenge, but both the plates and the description are from the works of Stukeley, Sir R. C. Hoare, and others. His opinion is that Stonehenge 'was raised by the Druids, the priests of the nation, who were its sacred architects.'

About fifty years back Mr. Waltire gave lectures on Stonehenge, illustrated by models and drawings, and fancifully represented the temple as a place devoted to sacred and mysterious rites, and as forming a planisphere, in connection with the surrounding barrows and other works. Taking up a part of this theory, but allowing a wider latitude to conjecture, the Rev. E. Duke has lately published, in the 'Salisbury Journal,' a long series of essays, in which he endeavours to show that Stonehenge was one of the members, or planets, of a vast planetarium, representing the solar system, and extending over a wide extent of country, 'on a meridian thirty-two miles in length.'

The late John Rickman, in the 'Archæologia,' vol. xxviii., p. 399, supposes that 'Silbury hill, the Abury circus, and the avenues of approach to it, were not constructed earlier than the third century of the Christian æra, and that the more difficult operations requisite for the formation of Stonehenge may be assigned to the next century, or (to speak with due caution) that this temple was completed before the final departure of the Romans from Britain.'

The Rev. Thomas Maurice, in 'Indian Antiquities,' vol. vi., has a dissertation on Stonehenge, and endeavours to show that the Druidical rites and ceremonies of the West were derived from antient India, and that this monument or temple must have been erected more than 500 years before the Christian æra.

In 'Palestine: the Bible History of the Holy Land,' 8vo., 1841, by John Kitto, there is a learned essay 'On Antient Monuments of Stone, Druidical Remains,' &c., with an elaborate review of this much controverted subject.

In conclusion it may be observed that there appears much less reason for ascribing the erection of Stonehenge to any of the successive conquerors or colonists of Britain, than to its original inhabitants the Celtic Britons; and if this be admitted, it is a probable conjecture that the structure was erected for religious purposes under the direction of the Druids. The practice of commemorating an important event by raising a number of stones, is of the greatest antiquity; and there is nothing in the history either of the Romans or the Saxons to lead us to suppose that those nations ever erected temples or monuments like the stone circles of Avebury and Stonehenge.

STONEHOUSE, a township and parish in the county of Devon, 217 miles west by south from London, and about midway between the large towns of Plymouth and Devonport.

Apart from local distinctions Stonehouse would be considered as a component part of the one great town which Plymouth, Devonport, and Stonehouse really constitute. In a narrower point of view, Stonehouse would be regarded as a suburb of Plymouth, being on the same level, and connected with it by uninterrupted lines of buildings; while it is separated from Devonport by a creek, and by a long and steep ascent beyond, which is unoccupied by buildings: a toll-bridge over the creek makes the separation still greater. But when the Reform Act was drawn up, it was deemed proper to associate Stonehouse with Devonport in the exercise of the elective franchise, which neither had previously enjoyed. Stonehouse was constituted a township by this act, and is divided into two wards. It is under the jurisdiction of a bench of county magistrates, who sit every Tuesday at the so called town-hall, which is only a part of the watchhouse, which is used for the confinement of offenders until they are removed by order of the magistrates.

Stonehouse was originally called Hippeston, the name of a mansion first inhabited by Joel de Stonehouse, in the reign of Edward III. The original, or *West* Stonehouse, was on the other side of the water, at Cremhill, under Mount Edgcumbe, to the noble proprietor of which *this*, usually distinguished as *East* Stonehouse, also belongs.

For several centuries Stonehouse was a fishing village, with a small chapel. During the civil wars its population was between 700 and 800. The establishment of the Royal Naval Hospital in 1762, and of an extensive depôt for the Royal Marines in 1784, gave a great impulse to the prosperity of the place, which has, within the present century, been greatly strengthened by the late earl of Mount Edgcumbe, who, by granting leases on liberal terms, has caused the town rapidly to increase. The recent removal of the Royal Victualling Establishment from Plymouth to the extremity (Cremhill Point) of the peninsula on which Stonehouse is situated, will increase its prosperity.

The streets of Stonehouse are wider and more regularly laid out than we usually see in a town of its class. The houses are very neat, but small, except in two or three streets, which the gentry inhabit. There is no public building of any note, except those pertaining to the port of Plymouth, which have been already named. The parochial chapel of St. George, which has 1000 sittings, was built in 1789, and is a perpetual curacy, in the gift of the vicar of St. Andrews, Plymouth. The new chapel of St. Paul's, which has 950 sittings, was opened in 1831, and its minister is appointed by the incumbent of the parish. There is another episcopal chapel in the Royal Hospital. The Methodists, Calvinists, Independents, Baptists, and Roman Catholics, have their several places of worship, with sittings altogether for 2033 persons. In Stonehouse there are six commercial and classical schools, with 378 pupils; a national school with 188 boys and girls, and an infant school with 113 boys and girls. The Sunday schools are five, one belonging to the church, and the rest to the several denominations, with 752 children. Stonehouse has the usual charitable societies for the benefit of the poor, and an almshouse for eight poor widows has been lately established by Mrs. Bint. The workhouse is a plain structure, erected in 1801. There is a small library and a reading-room, connected with the Naval Club, which is not confined to the naval service. The market-place is a neat and convenient building. There are two annual fairs, one held in May, the other in September. The population of Stonehouse was 3407 in 1801, 6043 in 1821, and 9712 in

1841; but the last number is a very slight increase (141) upon 1831.

STONESFIELD FOSSILS. The accumulation of organic remains in the thin slaty limestones of Stonesfield is one of the most remarkable phenomena known regarding the distribution of the fossils in the oolitic rocks. Coniferous, cycadeous, and filicoid plants; lamelliferous corals, conchifers, gasteropods, cephalopods, crustaceans, insects, ganoid fishes, terrestrial and aërial saurians, marsupial mammalia; all these occur together, and suggest to the naturalist a variety of inferences and speculations. Viewed in their most general relations, the slaty beds of Stonesfield appear to be deposits produced in the sea near the shore in shallow water, at points to which fresh-water currents might send, at intervals, some of the spoils of the land. The marine conchifers are often found with valves united, and otherwise in conditions which indicate residence on or near the spot where they are buried; but the broken state of the land plants, the scattered elytra of insects, the detached state of the teeth and bones of fishes, saurians, and mammalia, seem the effect of transport from some distance. A great distance cannot well be supposed, for in that case we must imagine the course of a great river, and look for its effects over much wider areas than that of the Stonesfield fossils. There are indeed several rather similar deposits, and perhaps of the same or nearly the same geological date, in the oolitic series of Northamptonshire and Yorkshire, but they seem to be due to separate areas of littoral agitation.

Admitting then the original *habitat* of the Stonesfield fossils to be nearly identical with their present locality, we may venture to ask, to what local fauna and flora in any of the natural regions of the existing land and sea does the Stonesfield series of life offer the greatest analogy? Professor Phillips (*Treatise on Geology*, 1837, vol. i., p. 105), in discussing generally the resemblance of fossil and recent local groups, observes that 'it is impossible to turn to Australia without a suspicion that the anomalous productions of that region have more than the average resemblance to the primeval fauna and flora. For here, and near it, tree-ferns, *cycadeæ*, araucariæ, casuarinæ, grow upon the land; corals and sponges abound on the coast even of Van Diemen's Land; while *trigoniæ*, cerithium, isocardia, a cardium like C. hillanum of the green-sand, and quadrupeds of the peculiar marsupial races to which the Stonesfield animal is referred by Cuvier, seem to invite attention to the yet unexplored sea and land of this prolific region, as likely to yield still further analogies to antient animals and plants, and by consequence to furnish new and important grounds for determining the antient physical conditions of the globe.' A similar view of the determinate analogy of the races of animals and plants now living in Australia, and long since buried in the oolitic strata, has presented itself to Professor Owen, whose decision of the marsupial and mammiferous character of the lower jaws of quadrupeds found at Stonesfield is a gratifying confirmation of the opinions of Cuvier and Buckland, and one of the most important data for the palæontologist. (*Report to the Brit. Assoc.*, 1841.)

There is yet no complete catalogue published of the very numerous species of fossils found at Stonesfield, and preserved in the collections of Buckland and other geologists. Many of the plants are noticed by Sternberg, Brongniart, and Hutton; Mr. Sowerby has figured many of the shells; the work of Agassiz may be consulted for the fishes; Dr. Buckland's *Bridgwater Treatise*, and Professor Owen's *Report*, already alluded to, and other works of the same author, for the reptiles and mammalian remains.

STONHOUSE, SIR JAMES, who was originally a physician, afterwards a clergyman, and who became a baronet late in life, on the death of a distant relation, was born July 20, 1716, at Tubney, near Abingdon. His father was a country gentleman, and died when his son was only ten years old. He was educated at Winchester School, and afterwards at St. John's College, Oxford, where he took his degree of M.A. in 1739, that of M.B. in 1742, and that of M.D. in 1745. He was indebted for much of his medical knowledge to Dr. Frank Nicholls, with whom he resided for [illegible] years in his house in Lincoln's Inn Fields. He attended St. Thomas's hospital for two years under Sir Edward Wilmot, Dr. Hall, and Dr. Lethe[illegible]nd, and carried on his medical studies for two years more at Paris, Lyon, Montpellier, and Marseille. On his return he settled at Coventry, where he married the eldest daughter of John Neale, Esq., member of parliament for that city. This lady, who died in 1747, soon after their marriage, in the twenty-fifth year of her age, is introduced as one of the examples of frail mortality in Harvey's 'Meditations,' and is further commemorated there in a note. In 1743 Dr. Stonhouse removed to Northampton, where his practice became very extensive. He was in all respects a great benefactor to the poor, and, among other schemes for their relief, founded the County Infirmary. During his residence at Northampton the celebrated Dr. Akenside in vain attempted to get a footing, for he found that Dr. Stonhouse, as Johnson observes, in his Life of Akenside, 'practised with such reputation and success, that a stranger was not likely to gain ground upon him.' After twenty years' practice in Northampton, Dr. Stonhouse quitted his profession, assigning as his reason that his practice was too great for his time and health; but neither the natural activity of his mind nor his unceasing wish to do good would permit him to remain unemployed. As he was particularly fond of the study of divinity, he determined to take orders, and was ordained deacon by the special favour of the bishop of Hereford, in Hereford cathedral, and priest the week after, by letters dismissory to the bishop of Bristol, in Bristol cathedral. In May, 1764, he was presented to the living of Little Chevrel, and in December, 1779, to that of Great Chevrel, where he applied himself to the duties of his station with fervour and assiduity, and became very popular as a preacher. About ten years before this, he had married his second wife Dr. Stonhouse's piety, for which he was most admired, had not always been uniform. He tells us that he imbibed erroneous notions from Dr. Nicholls, and that he was for seven years a confirmed infidel, and did all he could to subvert Christianity. He went so far as to write a keen pamphlet against it; the *third* edition of which he burnt. He adds, 'for writing and spreading of which, I humbly hope, as I have deeply repented of it, God has forgiven me, though I never can forgive myself.' His conversion to Christianity (which he attributes to some of Dr. Doddridge's writings), and the various circumstances attending it, were such, that he was persuaded to write the history of his life. This he intended for publication after his death, but, in consequence of the suggestion of a friend, and his own suspicions lest a bad use might be made of it, he was induced to destroy it. He died at Bristol-Wells, Dec. 8, 1795, in the eightieth year of his age. Among other ways of doing good, Sir James Stonhouse was convinced that the dispersion of plain and familiar tracts on important subjects was one of the most important and he accordingly wrote several of these, some of which have been adopted by the Society for Promoting Christian Knowledge. Much of his general character and conduct, his sentiments, and the vicissitudes of his professional employment, may be learned from his correspondence, published in 1805, 2 vols. 12mo., with the title, 'Letters from the Rev. Job Orton and the Rev. Sir James Stonhouse,' &c. See also *Gent. Mag.*, lxv., lxvi., and lxxxi.; and Chalmers, *Biog. Dict.*

STONY STRATFORD. [BUCKINGHAMSHIRE.]

STOP, a set of pipes in an organ. [ORGAN.]

STOPPAGE IN TRA'NSITU is the seizure by the seller of the goods sold during the course of their passage to the buyer.

In explaining the nature of the right of stoppage in transitu, it will be necessary to show—

1. Under what circumstances it exists.
2. By whom and how it may be exercised.
3. How it may be lost.
4. What is the effect of it.

When goods are sold on credit without any agreement as to the time of delivery, the right to the possession of them, as well as the property in them, vests immediately in the buyer. Originally it would appear that the right to the possession and the ownership were considered absolute, the consequence of which, in case of the buyer's bankruptcy or insolvency immediately after the sale, was, that the goods, although unpaid for, and still in the possession of the seller, formed part of the insolvent buyer's estate, and were liable to distribution among his creditors. This was at variance with the merchant law of other nations, and was considered inequitable, and, accordingly, about the year 1690, the Court of Chancery first introduced the doctrine of stoppage in

transitu. (Wiseman v. Vandeput, 2 Vern., 203; Snee v. Prescott, 1 Atk., 245.) It has been since universally recognised in the courts of common law. By virtue of this doctrine the seller was held entitled, in case of the insolvency or bankruptcy of the buyer, to stop the goods at any time before they came into the buyer's possession. During such time they are said to be in transitu, by which, as Lord Mansfield says, is meant every sort of passage to the hands of the buyer; that is, until they have reached the place agreed upon between the buyer and the seller as the place of their ultimate destination. This is not necessarily the actual premises of the buyer; it may be any place, as, for instance, a seaport, the warehouse of the carrier, or even of the seller himself, if such has been assigned as the place of destination. The transitus however continues not only while the goods are actually in motion, but also while they are in any place of deposit connected with their transmission. Goods in the custody of a warehouseman may thus be said still to be in transitu, and with respect to goods so circumstanced, questions very frequently arise as to whether the right of stoppage in transitu still exists or not. When these questions are not determinable by the express terms of the contract, it may become material to inquire whether any other act remains to be done on the part of the seller previous to the actual delivery. If not, it is to be presumed that the transitus is at an end. The buyer's right to possess may be rendered absolute by various acts, as by the seller giving up to the buyer the key of the warehouse where the goods lie, the delivery of part from the bulk of them, the exercise of acts of ownership upon them by the seller, with permission of the buyer. [SALE.] After the transitus of the goods has commenced, it was held by Lord Kenyon that the natural termination of it could not be anticipated by the act of the buyer in meeting the goods and taking possession of them while on their route. The law however now appears to be, that if an actual delivery has taken place, even though by means of such an anticipation of it, the right of stoppage is lost. The part delivery of goods does not destroy the right. In a case where part of a cargo was delivered on a wharf, and was afterwards reshipped, it was held that the seller still retained the right of stoppage in transitu as regarded the whole of the goods.

When the transitus has once been entirely accomplished, the right of stoppage in transitu is extinguished, and cannot again be revived.

The right of stoppage in transitu may be exercised, although a part of the price of the goods has been paid, but not if upon the general account between the buyer and the seller the balance is in favour of the buyer. A seller is justified in refusing to part with his goods under such circumstances as would entitle him to stop them in transitu after the transitus has commenced.

2. The seller, or some one acting on his behalf, is the only person who can exercise the right of stoppage in transitu. No other person, however much interested, possesses this right. Thus a surety to the seller for the payment of the price of the goods, or one who had a lien upon them before he parted with the possession of them, has no right to stop them in transitu. A party however who bought goods for a correspondent from third parties, who were unknown to his correspondent, and charged him a commission upon the price, was held to be, as regarded his correspondent, in the light of an actual seller, and therefore entitled to stop the goods in transitu.

The buyer of goods cannot act as the agent of the seller for the purpose of stopping goods in transitu. No act of his, such as placing the goods in the hands of third parties, &c., will operate as a stoppage in transitu.

In order to effect a stoppage in transitu, it is not necessary that corporal possession of the goods should be obtained. A notice to a wharfinger not to surrender them to the buyer, to a carrier not to deliver them, &c., is a valid exercise of the right.

3. The right of stoppage in transitu being a right of the seller against the buyer, no right, generally speaking, derived to third parties through the buyer only, can defeat it. Such parties stand in the same condition towards the seller as the buyer stands, through whom their rights are derived. Thus a carrier cannot, as against the seller, claiming a right of stoppage in transitu, detain the goods on the ground of a lien upon them for the carriage of other goods for the buyer. If the buyer resell the goods and become insolvent before they have come into his possession, the right of stoppage in transitu still remains.

But in the case of goods which are subject-matter of a bill of lading, a dock-warrant, &c., the rule of law is otherwise. A party to whom a bill of lading is consigned, or a dock-warrant indorsed, has a property which may be the subject of an assignment; and a *bonâ fide* assignee upon performance of the conditions, if any, of the bill of lading, becomes entitled, upon the assignment, to the possession of the goods absolutely as against the consignor, even in case of the insolvency of the consignee. This was decided as to bills of lading, after great consideration, in the case of Lickbarrow v. Mason (6 East, 21). But if the assignment of the bill of lading is fraudulently accepted by the assignee for the purpose of defeating the consignor's right of stoppage in transitu, it will be inoperative for that purpose, and will give the assignee, as against the consignor, no right beyond that possessed by the consignee himself at the time of the assignment.

By the 4 Geo. IV., c. 83, and 6 Geo. IV., c. 94, a factor is invested with a power of pledging, even for debts of his own, bills of lading, the property of his principal, when have been consigned to him [FACTOR]; but if he pledge also bills belonging to himself, the principal has a right to compel the pledgee to apply in the first instance the whole proceeds of the latter towards discharging the debt due from the factor to the pledgee. And if the consignor of a bill of lading assigned away in pledge, has taken the proper steps for exercising his right of stoppage in transitu against the consignee, he will be entitled to recover from the assignee the overplus of the proceeds that remains after satisfying the debt for which it has been pledged.

4. It would appear, although the point has never yet been expressly decided, that the exercise of the right of stoppage in transitu does not immediately rescind the sale and revest the property of the goods in the seller. Buller observes that it gives him a right to 'retain them till the original price be paid.' By 'original' he means the price bargained for at the time of the purchase, as distinguished from the value in the market at a subsequent period. The position also that the seller still retains the right to stop in transitu, although part of the purchase-money is paid, seems inconsistent with the supposition that the exercise of the right amounts to a rescission of the contract and sale. If this be correct, when the seller stops the goods in transitu, they still remain the property of the buyer, subject to being redeemed by him from the possession of the seller on payment of the price agreed on. They probably continue subject to this condition until the time allowed for credit has expired, where a time has been fixed on, and where it has not, until a reasonable time has elapsed. Probably also, in the case of goods of a perishable nature, the seller might be held to be authorized to sell the goods for the benefit of both parties. (Abbot *on Shipping*, tit. 'Stoppage in Transitu;' Cross *on Lien and Stoppage in Transitu*; Smith's *Leading Cases*, note to 'Lickbarrow v. Mason.)

STORACE, STEPHEN, a composer whose auspicious and brilliant career was arrested by the hand of death just as he had attained the age when most of those who are destined to distinguish themselves are but beginning to be generally known, was born in London, in 1763. His father, a Neapolitan (who added a *t* to his name on his coming to England), played the double-base at Drury Lane theatre, and married a sister of the well-known Dr. Trusler (who was famous by her manufacture of plum-cakes at Marylebone Gardens), the fruits of which union were, the subject of the present sketch, and *Anna*, the justly celebrated singer.

When about twelve years old, Stephen was placed by his father in the Conservatorio St. Onofrio, at Naples, where his progress fully justified the sanguine expectations excited in London by the budding of his genius. After completing his studies, he visited the different cities of Italy, giving various proofs of his talents, accompanied by his sister, a pupil of Sacchini, who at once was recognised as a first-rate vocalist. They then proceeded to Vienna, and reached the imperial city at the time that the Duke of York (then Bishop of Osnaburg) arrived there, who immediately honoured them by his notice, and never after withdrew his patronage. Signora Storace was speedily engaged at the emperor's Italian theatre, at a salary then thought prodigious—500*l.*; and her brother composed for the same an opera, *Gl' Equivoci*, the substance borrowed from Shak-

spere's *Comedy of Errors*. Portions of the music he afterwards used in his *Pirates*, and in *No Song, no Supper*.

In March, 1787, Storace and his sister returned to England, and were immediately engaged at the King's Theatre, the lady as first comic singer, and her brother as director of the music. Her success was most decided, but the intrigues of the Italian performers were too harassing for his sensitive nature, and he withdrew in disgust to Bath, devoting his time to drawing, an art for which he had much talent. In 1789 he produced his first opera at Drury Lane, *The Haunted Tower*, his sister appearing in the principal character, and this was performed no less than fifty times during the season. In 1790 he brought out *No Song, no Supper*, written by Prince Hoare. In 1791 appeared the *Siege of Belgrade*, altered by Cobb from *La Cosa Rara*, in which much of Martini's music is mixed up with Storace's. *The Pirates* was given, for the first time, in November, 1792: the performers were Kelly, Dignum, Sedgwick, Suett, John Bannister, Parsons, Mrs. Crouch, Miss De Camp (afterwards Mrs. C. Kemble), Mrs. Bland, and Signora Storace. The picturesque scenery was from designs made at Naples, by the composer himself. *The Prize* was brought out in 1793; *Lodoiska*, translated from the French by John Kemble, the music selected from the rival operas of the same name by Kreutzer and Cherubini, with additions by Storace, in 1794; and the same year also produced *The Iron Chest*, by George Colman, the younger, the incidental music by Storace. The composer's attendance on the first rehearsal of this, while under the influence of a severe attack of gout and fever, cost him his life. He returned from the theatre to his bed, whence he never rose again, dying on the 19th of March, in the thirty-third year of his age. Mr. Colman, in his preface to this play, describing the difficulties it had to encounter, thus eloquently mentions 'an event which deprived the world of a genius, and himself of a most intimate and valued friend;' and adds, 'nay, even the composer of the music—and here let me breathe a sigh to the memory of departed worth and genius, as I write the name of Storace—even he could not preside in his department. He was preparing an early flight to that abode of harmony where choirs of angels swell the note of welcome to an honest and congenial spirit.'

'At the time of his death he had a new opera, *Mahmoud*, in preparation. He had been to Bath to hear Braham, who then had not made his appearance on the London stage, and engaged him for Drury Lane. This however, by the assistance of Signora Storace and friends, was completed, and performed for the benefit of the widow and child of the composer, on the 30th of the month in which he breathed his last, and, supported by John Kemble's admirable acting, and Braham's not less admirable singing, was most successful.'

Our space will not allow us to particularise the other works of this highly-gifted amiable man; but it is only just to say of those here enumerated, that they 'abound in spirit, taste, science effectively but not pedantically displayed, strong feeling, and good sense;' and to add, that their author, in these as in other matters, evinced a vigorous and cultivated mind. 'His opinion on literary subjects was much respected by the best critics, and he was often consulted on points unconnected with his professional pursuits.' (*Harmonicon*, vol. vi.)

STORAX. [STYRAX.]

STORK, ABRAHAM. Notwithstanding the great merits of this eminent marine painter, and the high estimation in which his works have always been held, we cannot find that any author has been able to ascertain the year of his birth, or the master under whom he studied, or indeed whether he had any instructor. It is certain however that he was a most assiduous student of nature. He made accurate sketches of such objects, suited to his department of the art, as he thought might be introduced into his compositions, and hence every object in his pictures has the impress of truth.

He was equally successful in representing ships, either at sea or at anchor in port, either in calms or in storms. In his views of seaports, there is an extraordinary variety of ships, boats, and barges, with a great number of figures. This extraordinary number of figures engaged in every kind of employment incidental to a seaman's life, is in fact one of his chief characteristics. His most celebrated picture is that representing the reception of the Duke of Marlborough in the river Amstel, in which he has introduced an inconceivable number of vessels, barges, yachts, &c., superbly decorated, and crowded with figures, in a variety of costume, according to their rank and condition. Notwithstanding the extent of this composition, there is no confusion. It is painted with great spirit and highly finished. The colouring of this artist is very agreeable; his touch light, firm, and spirited; and his figures, though small, are designed with the utmost correctness. He died at Amsterdam, the place of his nativity, in 1708. (Pilkington; Fuseli; Bryan.)

STORK. [HERONS, vol. xii., p. 168.]

STORM, EDWARD, a Danish poet of some note, was the son of a clergyman at Guldbrandsdalen in Norway, where he was born, August 21, 1749, on the very same day with his literary contemporary Thomas Thaarup, whose mother is said to have dreamt that a rival to her own child would be born about the same time at Guldbrandsdalen. Storm began his literary career at the age of twenty-five, with a short heroic comic poem in six cantos, entitled 'Brøger.' Being written in hexameters, it recommended itself at the time as a novelty, nor is it without merit in regard to that minute descriptive painting of familiar objects and circumstances which stamps the Idyls of Voss; but it will bear no comparison with Holberg's 'Peder Paars,' with which it inevitably forces a comparison. He was far more successful in his 'Fables and Tales,' which are some of the best in the language, and acquired considerable popularity. They first appeared in 1783, and in the following year a second edition of them was published. His 'Infödretten,' a poem in four cantos, of the didactic class, and one or two other productions of a similar kind, have many fine passages and poetical beauties: his reputation however now rests chiefly on his lyrical productions, which have obtained for him a place in Danish literature by the side of Thaarup. Storm was for some time manager of the theatre at Copenhagen, which post he held at the time of his death in 1794. (*Skilderie af Kiöbenhavn.*)

STORNAWAY. [ROSS AND CROMARTY.]

STOTHARD, THOMAS, an eminent painter, the son of a publican who kept the 'Black Horse' in Long-acre, was born there on the 17th of August, 1755. At a very early age he evinced a taste for drawing in copying Houbracken's heads and other engravings. At eight years old he was placed at school at Stretton, near Tadcaster, the birth-place of his father. There he remained till he was of age to be apprenticed, when he was removed to London, and bound to a pattern-drawer for brocaded silks. The last year of his apprenticeship was given up to him in consequence of the decline of the trade. During the period of his service, Mr. Stothard exercised himself diligently in the study of nature from flowers and other subjects of still-life. His first efforts in a higher branch of art were designs for the 'Town and Country Magazine,' published by Harrison, in Paternoster-row; and soon after he gained high repute by his admirable compositions for Bell's 'British Poets,' and the 'Novelist's Magazine,' works which caused him to be employed in the illustration of almost every publication which for many years issued from the press in England requiring pictorial ornament. During this period he diligently studied at the Royal Academy. The first picture that he exhibited at that institution was the subject of Ajax defending the body of Patroclus. In the year 1785 he was elected an associate of the Royal Academy, and advanced to the rank of Royal Academician in 1794. In 1810 he was appointed deputy librarian to Mr. Birch, and on the death of that gentleman, in 1812, succeeded as librarian. Among the more important of his works may be enumerated his designs for Boydell's Shakspere, his Canterbury Pilgrims, the Flitch of Bacon, and the Wellington Shield, of the last of which he made an etching. His largest performance is the fresco painting of the staircase at Burleigh, the seat of the marquis of Exeter. He also designed the ceiling of the Advocates' Library at Edinburgh. The first style of painting adopted by Mr. Stothard was that of Mortimer, whose chief characteristics he closely imitated, indeed so exactly that many of his early works are mistaken for those of that vigorous painter. In his later productions however he followed the bent of his own genius, which was essentially gentle. He is supposed to have made upwards of five thousand designs, three thousand of which have been engraved, and although, as might be expected in so large a number, there is a sameness and mannerism of style, yet

truth, nature, simplicity, and grace are always apparent. In his comic subjects he was very happy, without in any one instance descending to vulgarity, whilst in his representations of female beauty his drawing is replete with purity of design and delicacy of execution. For several months before his decease, though Mr. Stothard's bodily infirmities prevented his attending to his labours as an artist, he would not relinquish his attendance at the meetings and lectures at the Royal Academy and in the library, notwithstanding extreme deafness prevented his hearing what was passing. He died on the 27th April, 1834, at his house in Newman Street, where he had resided more than forty years, and was buried in Bunhill-Fields burial-ground. He had a numerous family, the most eminent of whom was Charles Alfred, the author of 'Monumental Effigies of Great Britain.' A great number of his works have been engraved by Collins, Heath, Parker, Cromek, and Medland, and there are several engraved portraits of him, the principal of which are by Worthington, after Harlowe, and by Bond, after Jackson.

(*Annual Biography and Obituary; Gentleman's Magazine.*)

STOTHARD, CHARLES ALFRED, an antiquarian draughtsman, a son of Thomas Stothard, Royal Academician, was born in London, on the 5th of July, 1786. In 1807 he was admitted as a student of the Royal Academy, where he was soon distinguished for the chasteness and elegance of his copies from antique sculpture. In the following year he became a student in the Life Academy of the same institution, and attended at the British Institution, Pall Mall, to study from the pictures by the old masters. In 1810 he executed his first historical picture, 'The Death of Richard II. in Pomfret Castle,' in which the costume of the period was strictly adhered to, and the portrait of the king taken from his effigy in Westminster Abbey. As early as the year 1802, Mr. Stothard had been accustomed to make drawings from the monuments in the churches at Stamford and other places near Burleigh, the seat of the Marquis of Exeter. This occupation he undertook at the recommendation of his father by way of improving his knowledge of costume, as being valuable to a painter of historical subjects. This practice, together with a sight of some unpublished etchings by the Rev. P. Kerrich, of Cambridge, from monuments in the Dominican and other churches in Paris, suggested to him the idea of a work on the monumental effigies of Great Britain, of which the first number appeared in June, 1811. The work was accompanied by an advertisement, stating that the objects of the undertaking were, to give the historical painter a complete knowledge of the costume adopted in England from an early period of history to the reign of Henry VIII., to illustrate history and biography, and to assist the stage in selecting with propriety the costume for the plays of Shakspere. The success of the work was complete, and at once established the reputation of the author both as an antiquarian and an artist. In successive years he occupied himself in making excursions in search of monumental antiquities; and during the summer of 1815 he proceeded so far northward as the Picts' Wall to make drawings for Lysons' 'Magna Britannia.' In the same year he was appointed historical draughtsman to the Society of Antiquaries, and in 1816 was deputed by that body to make drawings from the tapestry at Bayeux. He left England for that purpose in September, and after having visited Paris, proceeded to Chinon, and discovered in the adjacent abbey of Fontevraud those interesting works the existence of which since the first French revolution had been matter of doubt, namely, the monuments of Henry II., his queen Eleanor of Guienne, Richard I., and Isabella of Angoulême, wife of King John. The abbey had been converted into a prison, and these effigies were placed in a cellar, where they were subject to injury from the prisoners. He made accurate drawings from these figures, and succeeded not without difficulty in discovering the painting on their surface. When visiting the abbey of L'Espan, near Mons, which he found converted into a barn, he discovered, under a quantity of wheat, the effigy of Berengaria, queen of Richard I. At Mons he also discovered the beautiful enamelled tablet of Geoffrey Plantagenet, which he considered the earliest specimen of a sepulchral brass, and of armorial bearings depicted decidedly as such. On his return to England, he suggested to government the removal of the Fontevraud effigies to Westminster Abbey, a suggestion which, though not acceded to, had the effect of causing them to be removed to a place of security.

In 1817 he made a second, and, in 1818, a third journey to Bayeux, in company with his wife, whom he had recently married. After completing his drawings of the tapestry, he made a tour in Normandy and Brittany, when he discovered at Ploermel the effigies of the dukes of Brittany, at Josselin those of Sir Oliver de Clisson and his lady, and at Vannes several others in a mutilated state. In 1819 he laid before the Society of Antiquaries the complete series of drawings from the Bayeux Tapestry, together with a paper, in which he proved that the tapestry was really a work coeval with the Norman invasion, a period assigned to it by tradition, and not, as attempted to be shown by the Abbé de la Rue, a work of the time of Henry I. The paper was printed in the nineteenth volume of the 'Archæologia;' and on the 2nd of July Mr. Stothard was elected a Fellow of the Society of Antiquaries. He soon after visited various places in Norfolk and Suffolk, for the purpose of making drawings for his monumental subjects, and whilst so engaged, he accidentally saw in a newspaper of the day an account of the discoveries then recently made on the walls of the painted chamber in the House of Lords. He immediately proceeded to London, and made a series of drawings from the paintings, of which, not long before his death, he prepared a paper, in which he investigated their age. In 1820 he travelled in the Netherlands, and, on his return, published the ninth number of his 'Monumental Effigies.' Early in 1821 he prepared a tenth number for publication, and also finished a large plate of the Royal Effigies at Fontevraud. He also began a work on seals, and left behind him about thirty unpublished drawings of the scarcest of our regal and baronial ones. Another of his undertakings was a work illustrative of the age of Queen Elizabeth. In May in the same year he left London for Devonshire, for the purpose of making drawings for the Rev. D. Lysons's account of that county. He arrived at Beer-Ferrers on Sunday the 27th, and after attending church, commenced a tracing of the portrait of Sir William Ferrers in the east window. For this purpose he stood on a ladder about ten feet from the ground, but one of the steps having broken, he was thrown with such violence against a monument, that he was killed on the spot. The most important work of Mr. Stothard is that before mentioned—the monumental effigies. The writings of Mr. Gough on the same subject are extremely valuable, but the delineating part contains so many errors, and bears so little resemblance to the style of the originals, that the labours of Mr. Stothard were appropriately devoted to the preservation of accurate as well as tasteful representations of those relics of antiquity.

(*Memoirs of the Life of C. A. Stothard*, by his widow; *Annual Biography and Obituary; Gentleman's Magazine.*)

STOUR. [ESSEX; KENT.]

STOURBRIDGE. [WORCESTERSHIRE.]

STOURPORT. [WORCESTERSHIRE.]

STOVE. [WARMING AND VENTILATION.]

STOVE-PLANTS. [HOTHOUSE.]

STOW, JOHN, was born in London, about the year 1525. His father Thomas Stow belonged to the company of Merchant Tailors, and both his father and his grandfather appear to have been tradesmen of credit and substance. Both had monuments in the church of St. Michael's, Cornhill, in which parish they dwelt, and which has probably also the honour of having given birth to the subject of the present article.

It is certain that Stow, in the earlier part of his life, followed some trade, and he is expressly called a tailor in at least one document of the time. It appears that in his own day he was regarded as secretly attached to the old religion, and he was more than once exposed to some danger on that account: he was certainly however no bigoted Romanist: his inclination in that direction was an antiquarian rather than a theological feeling; he did not sympathise much with the destructive work of the Reformation; but he does not deny that both doctrine and practice were purer under the new than under the antient system; and his chief patrons and friends were some of the heads of the Established Church, to which also there can be no doubt that he always professed to belong.

He had probably been given from early life to the investigation of the national antiquities; but about his fortieth year, as we learn from himself, he left his business and applied himself altogether to this his favourite study. The

different accounts he gives however vary somewhat as to the time at which he took or acted upon this resolution. Thus, in the edition of his 'Summary,' published in 1567, he describes the compilation of the work some years before as having resulted from his thinking it good at vacant times to take him to his 'old delectable studies;' in the edition of 1573, he speaks of its being then eight years, since, leaving his own peculiar gains, he had consecrated himself to the search of our famous antiquities: in the edition of 1598, his expression is, that it was 'full thirty-six years' since he had done so; and in the dedication of his 'Annals' to Archbishop Whitgift, dated 24th November, 1600, he says, 'It is now nigh forty years . . . . . since I first addressed all my cares and cogitations to the study of histories and search of antiquities.'

The accounts that have been given of Stow's publications are for the most part very defective, confused, and contradictory. Passing over for the present his 'Survey of London,' about which there is no difficulty, we will first exhibit the statements we have met with as to his other works, that have the air of having been drawn up with the greatest care:—

I. Strype, in an elaborate 'Life of Stow,' extending to 27 double-columned folio pages, prefixed to his edition of the 'Survey of London,' tells us that the first book Stow put forth of the history of England was his 'Summary of the Chronicles of England,' from the coming in of Brute unto his own time; that he set about this in 1562, on the suggestion of Lord Robert Dudley (afterwards the famous earl of Leicester); that when the work was published (it is not said in what year), it was dedicated, 'with the continuation and increase thereof from time to time,' to that nobleman; that not long after, namely, in 1573, it was enlarged and reprinted, and again dedicated to Leicester, in an address in which Stow speaks of his lordship's 'generous acceptation of many works presented unto him by others as well as himself,' and states that 'he fell upon the study and pains of examining and collecting of this English history five years before he set forth this Summary;' that before this larger Summary came forth, he had published several lesser Summaries; that 'after twenty-five years,' (it is not said from what time,) his fortune growing low, he addressed a petition to the lord mayor and aldermen, in which, as Strype quotes the words from the original, though without giving us the date of the paper, he represented that for the space of twenty-five years past (besides his 'Chronicle,' dedicated to the earl of Leicester), he had set forth various Summaries dedicated to the lord mayor, aldermen, and commoners of the city, and that he minded shortly, if God so permitted, to set forth a far larger Summary or Chronicle of the city and citizens thereof than had yet been published: that some years after he addressed another petition to the mayor and aldermen, in which, after telling them that he was of the age of threescore years and four, he goes on, as before, to speak of the Chronicles (not Chronicle) and divers Summaries he had set forth, 'for the space of almost thirty years last past;' that after his Summary, he published, in the year 1600 (now after near forty years study of history) his 'Flores Historiarum,' that is, his 'Annals of this land,' from the time of the antient Britons to his own, 'which,' however, 'were nothing else but his Summary greatly enlarged;' that 'this book was set forth again in the year 1605, by Stow himself, with enlargements, in the black letter, in a thick quarto;' that he intended to publish, or leave to posterity, a far larger volume, but died before he could accomplish that design; 'and where that laborious work of his is,' adds Strype, 'I know not; only we are told that he left the same in his study, orderly written, ready for the press, but that it came to nothing. We all know that another edition of the Annals was set forth in folio by Edmond Howes, some years after the author's death. Perhaps those historical collections are preserved in the curious repository of Sir Simonds Dewes, as some say the rest of Stow's books and papers are, many of which are now reposited in the incomparable library of manuscripts erected by the earl of Oxford and Mortimer.' Such is the substance of between four and five long wordy columns which Strype devotes to the matter. 'So that,' he concludes, 'Stow's histories, which he collected and wrote, were three, viz. his Chronicle, his Summary of Chronicles, and his Annals. The two latter he printed; but that Chronicle which he called his largest work was never printed.'

II. The account given by the writer of the article on Stow in the 'Biographia Britannica' is, that his 'Summary of the Chronicles of England' first appeared in 1565; that it was reprinted with additions and improvements in 1570, 1575, and 1590, and, with a continuation by Edmond Howes, in 1607, 1610, 1611, and 1618; that an abridgement of this 'Summary' appeared in 1566, and was reprinted with continuations in 1567, 1573, 1579, 1584, 1587, 1598, and 1604; that there was an edition of the 'Summary,' under the title of 'Annales,' published in 4to. in 1592; but that his 'Annals,' properly so called, first appeared in 1600, under the title of 'Flores Historiarum, or Annals of England;' and finally, that 'from his papers Edmond Howes published afterwards that folio volume which goes under the name of Stow's Chronicle,' first in 1615, and again in 1631, but that 'even this doth not contain all that "far longer work" which Mr. Stow mentions, and intended to have published, leaving it in his study orderly written, ready for the press.' The manuscript, it is added, 'is not in the British Museum, with others of our author's manuscripts,' which, as already stated, were among those of the earl of Oxford, now forming what is called the Harleian Collection.

III. Watt, in his 'Bibliotheca Britannica,' makes Stow to be the author of no fewer than four different printed works on English history, namely—1, his 'Summary of English Chronicles,' of which there were editions, in 8vo., in 1565, 1570, 1575, 1579, 1590, and, with continuations by Howes, in 1607, 1610, 1611, and 1618; 2, his 'Summary of Chronicles abridged,' printed in 8vo., in 1566, 1567, and 1579; 3, his 'Chronicles of England,' published, in 4to., in 1580, 1584, 1587, 1592, and, under the title of 'Flores Historiarum, or Annals of this Kingdom,' in 1600 and 1604, each time with a continuation; 4, his 'Annals, or a General Chronicle of England,' 12mo., 1573; 4to., 1592; 16mo., 1598; 4to., 1602, 1605, and, continued by Howes, folio, 1614-15, and again 1631. This account appears to be a mere jumble of blunders, made up from the 'Biographia Britannica' and probably the entries in some booksellers' catalogues.

It does not appear that there are really more than two historical works of Stow's which can properly be called different, namely, his 'Summary' and his 'Annals.'

1. The earliest edition of the 'Summary' that we have seen is a very small 18mo. volume, in black letter, entitled 'The Summarie of Englishe Chronicles (lately collected and published), abridged and continued till this present moneth of November, in the yeare of our Lord God 1567, by J. S.; imprinted at London, in Flete Street, nere to S. Dunstone's church, by Thomas Marshe.' But this is not the first edition of the book, for in a dedication to the Rt. Hon. Roger Martin, lord-mayor, the aldermen, and commoners of London, the author states that in first publishing this his small travail of English Chronicles, he thought good to dedicate it to the earl of Leicester; 'but now,' he adds, 'at the request of the printer and other of my loving friends, having brought the same into a new form, such as may both ease the purse and the carriage, and yet nothing omitted convenient to be known; and, besides all this, having example before my face to change my patron (reserving still my printer, as careful of his advantage rather than mine own), I am bold to submit it unto your honour and worship's protection,' &c. Another edition of the same size, but a greater number of pages, is entitled 'The Summarye of the Chronicles of Englande, lately collected, newly corrected, abridged, and continued unto this present year of Christ, 1573, by J. S.' It is dedicated to the Rt. Hon. Lionel Ducket, lord-mayor of London, the aldermen, and commoners; and in a curious address 'To the reader,' Stow says, 'Calling to memory, gentle reader, with what diligence, to my great cost and charges, I have travailed in my late Summary of the Chronicles, as also the dishonest dealings of somebody towards me (whereof I have long since sufficiently written and exhibited to the learned and honourable),* I persuaded with myself to have surceased from this kind of travail, wherein another hath used to reap the fruits of my labours. But now, for divers causes thereto moving me, I have once again briefly run over this small abridgment,' &c. There were probably many editions of the 'Summary' after this; but the only other published in Stow's lifetime which we have seen is one, also in 18mo., and in black letter, printed in 1598, which has his name at

* The person alluded to is his brother chronicler Richard Grafton, as appears from various indications.

full length on the title-page, and is dedicated to the Right Honourable Sir Richard Saltinstow, Knt., lord-mayor of London, the aldermen, the master, wardens, and assistants of the Merchant Tailors, and all the commons of the same city. In the dedication he speaks of the former editions of his 'Summary,' and also his 'late published Chronicle and Annals;' and again, of this his 'abridged Summary,' and other his 'larger Chronicles;' but we believe these various expressions refer only to one other work besides the 'Summary.' The next edition of the 'Summary' that we have met with is entitled 'The Abridgment of the English Chronicle, first collected by M. John Stow, and after him augmented with very memorable antiquitties, and continued with matters forreine and domesticall, unto the end of the yeare 1610, by E. H., gentleman; imprinted at London for the Company of Stationers, 1611.' This volume is a 12mo., in black letter, like its predecessors; but the type is larger, and it does not seem to contain, with the exception of the Continuation, much more than what Stow had already printed, although Howes, the editor, tells us that, besides the time the present edition had cost him, he had laboured five years on a preceding edition of the work, which appears to have been published in 1607. The present volume has two dedications, one to Sir Henry Rowe, who was lord mayor in 1607, the other to Sir William Craven, who was elected to that office in 1610. Stow's 'Summary' seems to have been in constant demand for half a century after its first publication; it was the popular manual of our national history; hence the book was laid hold of by the Stationers' Company, who probably brought out new impressions of it every three or four years, continued to the date of publication like their almanacs and other similar handbooks.

2. Of the 'Annals,' a copy now before us in 4to. and black letter wants the title page, but appears to have been printed in 1592, to which year the history is brought down. At the end, on p. 1295, the author, addressing the 'good reader,' says, 'I desire thee to take these my labours in good part, like as I have painfully to my great cost and charges, and not for hire, out of many old hidden histories and true records of antiquity, brought the same to light, and freely, for thy great commodity, bestowed them upon thee: so shalt thou encourage me to publish a larger volume and history of this island, princes of the same, and accidents of their times, which I have gathered, and is ready to the press, when God shall permit me.' Stow's 'Annals,' although of course mentioning the same facts, with many others, as his 'Summary,' is altogether a different work from that: even this edition of 1592 must contain at least ten times as much matter as the most extended edition of the 'Summary.' Another edition, also in 4to. and black letter, a copy of which is in the British Museum, is entitled 'The Annales of England; faithfully collected out of the most authenticall authors, records, and other monuments of antiquity; lately collected, since encreased, and continued from the first habitation untill this present year 1605; by John Stow, Citizen of London. Imprinted at London for George Bishop and Thomas Adams. Cum privilegio regiæ majestatis.' This edition has the dedication to Whitgift, dated 1600, already mentioned, and also a 'Preface or Address to the Reader,' which contains the greater part of the Dedication prefixed to the various editions of the 'Summary,' and inscribed to the lord mayor for the time being. In his Dedication to Whitgift the author states that his laborious collections have now at length grown into a large volume, 'which,' he says, 'I was willing to have committed to the press, had not the printer, for some private respects, been more desirous to publish Annals at this present;' and he afterwards expresses his hope of the archbishop's favourable acceptance of the present work, as but part of that which he 'intended in a more large volume.' In his Preface also he describes this edition of his 'Annals' as an abstract of a far larger work which he has gathered, and meant to have published; and at the end of the 'Chronicle,' on p. 1438, after soliciting as usual the reader's favourable acceptance of his labours, he adds, 'So shalt thou encourage me, if God permit me life, to publish or to leave to posterity a far larger volume, long since by me laboured, at the request and commandment of the Rev. Father Matthew Parker, Archbishop of Canterbury; but, he then deceasing, my book was prevented by printing and reprinting (without warrant or well-liking) of Rayner Wolfe's Collection, and other late comers, by the name of Raphael Holingshead his Chronicles.' We doubt if, with the exception of the continuation, there be almost anything in this edition of the 'Annals' which is not in the preceding edition of 1592. Nor does there appear to be much added to the portion of which Stow is the author in either of the editions published after his death by Howes, in folio, the first in 1615, the second in 1631. Of the latter, still in black letter, the full title is 'Annales, or a General Chronicle of England; begun by John Stow, and augmented with matters forraigne and domestique, antient and moderne, unto the end of this present year 1631, by Edmund Howes.' In his dedication to the king however Howes intimates that he had been no less than thirty years employed upon the work, and that he had undertaken and performed the task in consequence of his 'oath and promise made to the late most reverend prelate Doctor Whitgift, Lord Archbishop of Canterbury.' We do not find that he professes to have made use of any manuscript materials left by Stow.

Stow's other work, his 'Survey of London,' was first published, in a quarto volume, in 1598; and again, in the same form, with considerable additions, in 1603. After the author's death, a third edition, also in 4to., was published in 1618, by A. M. (Anthony Monday), who, according to Strype, 'made several additions (as he pretended) which, or much of which (as he hinted in his Epistle), he had formerly from Stow himself, who, while he was alive, delivered him some of his best collections, and used importunate persuasions with him to correct what he found amiss, and to proceed in perfecting a work so worthy.' A fourth edition, in folio, came out in 1633, professing on the title-page to be 'now completely finished by the study and labour of A. M., H. D. (Humphry Dyson), and others.' Strype gives C. J. as one of the contributors, meaning probably the C. I. whose signature is appended to the prefatory address to the reader. The next edition was that published by Strype, in 1720, in two folio volumes, each twice the size of the folio of 1633. Strype's additions indeed made the 'Survey,' for the greater part, a new work. The writer of the article on Stow in the 'Biographia Britannica' is, as far as we know, mistaken in his assertion (Note L.), that this edition was reprinted in 1756.

Stow, in various passages of his 'Annals,' claims the continuation of Holinshed's 'Chronicle' from 1576 to 1586, as his own handiwork. He appears to have at least supplied a great part of the materials for that portion of the work; but he is merely mentioned as one of several contributors in the Epistle to the Reader prefixed to the edition of 1587 by A. F. (Abraham Fleming), who besides takes to himself the credit of having digested the whole. In his 'Annals,' under the year 1400, Stow states that the edition of Chaucer published (by Speght) in 1560, was founded upon divers written copies corrected by him. Dr. David Powel, in his 'History of Cambria,' published in 1584, acknowledges that he derived important assistance from Stow, who supplied him with a considerable number of manuscript historians, of which he had made use. Stow had possessed himself of a large collection of curious and valuable manuscripts, some originals, some transcribed by his own hand; among the latter, the six volumes of Leland's 'Collectanea' (since printed by Hearne), which he sold to Camden for a life annuity of eight pounds a year.

The hard fate of Stow in his old age is well known. The laborious and acute investigator of antiquity, and faithful and graphic depictor of the manners and customs of his own time, was left by his countrymen, when he had reached his eightieth year, literally to beg his bread. Strype has given a letter from James I., referring to letters patent under the great seal, granted 8th May, 1603, authorising Stow to collect the voluntary contributions of the people throughout the greater part of the kingdom,* and also the actual brief or licence by which the same privilege was renewed to him the following year. The latter paper, in consideration of Stow having, 'for the good of the commonwealth, and posterity to come, employed all his industry and labour to commit to the history of chronicle all such things worthy of remembrance, as from time to time happened within this whole realm, for the space of five and forty years, until Christmas last passed (as by divers large and brief chronicles of his writing may appear), besides his

* This paper has been lately more correctly given from the original copy preserved in the Harleian Collection, by Mr. Bolton Corney, in his 'Curiosities of Literature Illustrated,' Greenwich, 1839, p. 40. The date of the letters patent referred to in the letter is there given the 8th of March (not May), 1603, which, according to the modern reckoning, would be March, 1604.

great pains and charge in making his book called his "Survey of London," wherein he spent eight years in searching out of antient records concerning antiquities both for London and Southwark,' and in consequence of his having forfeited the favour, and 'having left his former means, whereby he lived, only employing himself for the service and good of his country,' grants to him and his deputy, the bearer of the paper, licence for one year, to ask, gather, and receive the alms and charitable benevolence of all people in the counties and cities enumerated, and commands the authorities, at such times as Stow or his deputy shall come to any of their churches, or other places, to ask and receive the said gratuities, 'quietly to permit and suffer them so to do, without any manner let or contradiction.'

Stow died of the stone colic, on the 5th of April, 1605, and was buried in his parish church of St. Andrew Undershaft, where his monument, exhibiting his effigy, erected by his widow, is still to be seen. Strype says that he left four daughters, but whether any sons he could not learn.

It is stated by Mr. Corney, in his 'Curiosities of Literature Illustrated' (p. 41, note), that a memoir of Stow was then contemplated by John Gough Nichols, Esq., F.S.A.; but, as far as we are aware, it has not yet appeared.

STOW-ON-THE-WOLD. [GLOUCESTERSHIRE.]

STOWE. [BUCKINGHAMSHIRE.]

STRABISMUS. [SQUINTING.]

STRABO (Στράβων) was born at Amasia, in Cappadocia, before the Christian æra, but the time of his birth is unknown. His mother was the granddaughter of Lagetas, who was one of the two sons of Dorylaus, a skilful commander who had been employed by Mithridates Euergetes. (Strab., p. 477, 478, ed. *Casaub.*) Moaphernes, who had been employed by Mithridates Eupator, was an uncle of Strabo's father (p. 499), or (according to the true reading of Strabo's text) the uncle of his mother by the father's side. We are not informed who his father was. It has been observed that his name, Strabo, is the cognomen of Pompeius Strabo, the father of Pompey the Great, whence it has been conjectured that on his father's side there was some connection with the family of Pompey; but what this connection may have been, is purely a matter of conjecture. Strabo, the son, received a good education. He studied at Nysa, under Aristodemus; at Amisus, in Pontus, under Tyrannio; and at Seleuceia of Cilicia, under Xenarchus, who was a Peripatetic. He also visited Alexandria in Egypt, where he had the instruction of Boethus of Sidon, also a Peripatetic; and Tarsus, then a great school of learning, where he studied under Athenodorus, who was a Stoic. It thus appears that even during the course of his education Strabo must have been a considerable traveller, and his own work shows that he must subsequently have visited many places. Syria, Palestine, and Egypt, as far as the cataracts of Syene, were within the range of his travels. In Egypt he became acquainted with Aelius Gallus, who commanded a Roman expedition into Arabia, in the time of Augustus, and he visited in his company the vocal statue of Memnon at Thebes (p. 816). He also travelled in Crete, Northern Greece, and probably some parts of the Peloponnesus: he tells us that he saw Cleonae from the Acrocorinthus: but his remarks about Mycenae seem to show that he did not visit that part of the Peloponnesus at least (p. 377). He was personally acquainted with Italy, and he tells us that Elba, Corsica, and Sardinia are visible from the heights of Populonium (p. 223), from which it is a probable conclusion that he had seen those places from the Italian coast. It is also probable that he spent some time at Rome, where he would find materials for his geographical work.

There are various passages in his 'Geography' which indicate about what time they were written. In his sixth book (p. 288) he speaks of Germanicus and Drusus as still living; and in the thirteenth (p. 627) he speaks of Tiberius as the reigning emperor, and as having repaired the mischief done to Sardis by the great earthquake, A.D. 17. (Tacit., *Ann.*, ii. 47.) There are numerous other passages in this work in which he speaks of contemporary historical events, but perhaps none which can with certainty be referred to a later date than the great earthquake. In a passage of the fourth book (p. 206) he says that it was then the thirty-third year since the Norici had been reduced to obedience by Tiberius and Drusus, which took place about B.C. 15; according to which Strabo was writing his fourth book in the year A.D. 18.

Strabo's 'Geography' is mentioned by few antient writers: he is cited by Marcianus of Heraclea, Athenaeus, and Harpocration (Λευκάς, Αἰγαῖον); but Pliny, who might frequently have cited him in the geographical part of his work, never mentions his name; nor does it occur in Pausanias. He is mentioned by Josephus and by Plutarch, not as a geographer, but as an historical writer.

Very different opinions have been given of Strabo's geographical work. That he was deficient in mathematical knowledge is evident, and his accuracy in many cases is at least doubtful. To form a proper judgment of him, we must ascertain what he proposed his work to be, which may be collected from various passages. His work was to be practical, that is, adapted to the use of persons of a certain amount of education, and particularly personages engaged in administration. He says that a 'man who reads his work ought not to be so ignorant as never to have seen a sphere or the circles marked on it;' and he goes on to say, that a man who is ignorant of these and other like matters, which he has enumerated, and which belong to the elementary parts of knowledge, cannot understand his work. 'His work,' he says, 'is, in a word, for universal use, political and profitable to all, just as history is' (p. 12, 13); and 'as he had written an historical work (ὑπομνήματα ἱστορικά), useful, as he supposed, both for ethical and political philosophy, he determined to add to it a geographical work, which was of a like kind, and addressed to the same class of men, and chiefly to those in power; and, as in the former work, only what related to distinguished men and to distinguished lives was recorded, and things trivial and mean were omitted; so in his geographical work he should dwell only on things which were of note and of importance, and things in which there was something useful for example, and worth recording, and agreeable.' From this it appears that Strabo neither designed a mathematical treatise, nor an enumeration of astronomical positions, nor a treatise on the physical character of countries. His design was to write something which should give an educated man a general notion of the earth's surface, its political divisions, the chief peculiarities of each, and so much of its history as would enliven and explain his geographical description.

Accordingly Strabo produced a work which contains a great mass of useful information, but is not strictly a geographical work, and though systematic according to his notion of system, it does not deserve the name of a system of geography. Though he resided a long time at Alexandria, he derived little advantage from the labours of the geographers and astronomers of that school for the correction of positions and fixing the bearings of places with respect to one another, or for determining the general form of the regions which he describes. His taste indeed was for other studies than those which belong to the geographer.

The first two books of Strabo contain his general geography. In the first book he treats of the advantages of the study of geography, and discusses the geographical knowledge of Homer, which he rates highly. He then mentions the old geographers, as Hecataeus, Democritus, Eudoxus of Cnidos, and Ephorus of Cumae; and the more recent geographers, Eratosthenes, Hipparchus, Polybius, and Posidonius. He passes a critical judgment on the first two books of Eratosthenes, which leads him to various discussions, and to observations on the changes which the earth's surface has undergone. In the second book he extends his criticism to the third book of Eratosthenes, and to the three books of Hipparchus. He also discusses the merits of Posidonius and Polybius. Strabo has thus preserved many passages of the Greek geographical writers; but the author's judgment is often prejudiced and inaccurate. He severely criticises Hipparchus, and points out many of his errors, particularly as to the latitude of places. The latter part of the second book treats of the preliminary knowledge which the geographer requires. Strabo was acquainted with the fact of the spherical figure of the earth; and he determines the boundaries of the habitable part of it. The world is divided by the equinoctial circle into the northern and the southern hemispheres. The habitable portion is bounded on the north by a parallel of latitude which passes through Ierne (Ireland), and on the south by the parallel which passes through the Cinnamon country. The parts to the north of the first parallel are not habitable on account of cold, and those to the south of the second parallel are uninhabited owing to excessive heat. He follows Eratosthenes in his measurements, and compares them

with those of Hipparchus and Polybius. The habitable world (*οἰκουμένη*) is surrounded by water, and the Caspian Sea is a gulf of the Northern Ocean, a mistake which he might have corrected by the aid of Herodotus. The length of the habitable world is about double its breadth.

The third book contains the description of the Spanish Peninsula and the Balearic Islands; his principal authorities are Artemidorus, Posidonius, and Polybius. The fourth treats of Gallia, Britain, the Alps, and the tribes which inhabited the Alps, and the valleys belonging to that mountain-system: in general he follows the description of Cæsar, and he also used Artemidorus and Polybius, and probably the work of Aristotle on Political Constitutions, for his account of Massilia (Marseille): his description of Britain is exceedingly meagre; in treating of Thule he gives some account of Pytheas, but rejects his authority. The fifth and sixth books contain the description of Italy, Sicily, and the adjoining islands: he had probably seen a large part of these countries himself; yet he makes great use of Polybius, Posidonius, Ephorus, Eratosthenes, and many other writers: in treating of Corsica and Sardinia, he quotes the 'Chorographus,' without saying who is intended by the term: it has been suggested that the word has reference not to any particular individual, but to the results of the commission under the direction of Agrippa which made a survey of the empire: it has also been conjectured that Agrippa himself is meant by the Chorographus. In the seventh book Strabo treats of the countries on the Danube, and the parts included between the Danube, the Adriatic, and the Black Sea. the parts which treat of Macedonia and Thrace are lost, and in their place we have a scanty epitome. Strabo's authorities for this part of his work seem to have been very defective. The eighth, ninth, and tenth books contain his description of Greece and the Islands, in which he makes great use of Homer: Ephorus, Polybius, Posidonius, Hipparchus, Artemidorus, and Timosthenes, are also his authorities, in addition to many other writers. With the eleventh book Strabo begins his description of Asia, as to the extent and dimensions of which his notions are very inaccurate. He divides it into two main portions, determined by the range of Taurus. The western portion comprises the countries between the Tanais, Palus Maeotis, the Black and the Caspian Seas; the countries east of the Caspian, bordering on India; and Media, Armenia, and Cappadocia, to the Halys: these are described in the eleventh book. In the twelfth and following books he treats of Asia west of the Halys and the adjoining islands. His authorities for the eleventh book are, among others, Artemidorus, the historians of the Mithridatic wars; Metrodorus of Scepsis; and Patrocles, the admiral of Seleucus and Antiochus, for the account of the Oxus and Jaxartes. The twelfth book contains the description of Cappadocia, Pontus, Paphlagonia, Bithynia, Galatia, Lycaonia, Isauria, Pisidia, Mysia, and Phrygia, a great part of which is founded on his own personal knowledge. The thirteenth and fourteenth books conclude the description of Asia west of the Halys; and comprehend also the islands of Lesbos, Samos, Chios, Rhodes, and Cyprus. His description of the Troad, in the thirteenth book, is mainly founded on Homer; but he also uses Eudoxus, Charon, Scylax, and Ephorus. A great number of other writers were also used for the description of the several countries and places included in these two books. In the fifteenth book he passes to the description of the other portion of Asia, which is determined by the Taurus; and he first treats of the southern parts of the continent. In his description of India he chiefly follows Eratosthenes and the historians of Alexander, particularly Patrocles and Aristobulus. His notion of the form of India was entirely false, and he knew nothing of the great southern peninsula; but he speaks at some length of the customs and institutions of the people. After India he describes the Persian empire, comprehending under the general name of Ariana (Iran) the country bounded on the east by the Indus, and on the west by a line drawn from the Caspian Gates to the mouth of the Persian Gulf. Nearchus and Onesicritus are his authorities for the description of the coast: for other parts he uses Aristobulus, Eratosthenes, and Polyclitus. The sixteenth book contains the remainder of Asia: his authorities are generally the same as for the southern and eastern parts of Asia, with the addition of his own observations in Syria. The seventeenth book contains the description of Libya (Africa), and concludes with a brief sketch of the division of the Roman empire into provinces: Eratosthenes is his principal authority, but he also uses Agatharchides and Herodotus.

The text of Strabo is often corrupt, and there are many defective passages. There is extant an epitome, or Chrestomathia, of the whole work, which is referred to the tenth century A.D., which is sometimes useful in correcting the text. There are also extant various other extracts from the geography of Strabo. The historical work (*ὑπομνήματα ἱστορικά*) of Strabo, which he mentions in a passage already quoted, is lost: it was a continuation of Polybius, and extended at least to the death of Julius Cæsar.

Strabo first appeared in a Latin version in 1472. The first edition of the Greek text was printed by Aldus, at Venice, in 1516, fol. The edition of Isaac Casaubon, Geneva, 1587, folio, contains the translation of Xylander: this edition was reprinted after Casaubon's death, at Paris, 1620, folio, with his last corrections. Siebenkees undertook a new critical edition, for which purpose he collated several MSS.; he only lived to complete the first volume, which contains the first six books: this edition was finished by Tzschucke, and was published at Leipzig, 1796-1811, 6 vols. 8vo. Probably the best text of Strabo is by Coray, Paris, 1815-1819, 4 vols. 8vo., which has an index, but no translation. The 'Chrestomathia' is printed in Hudson's Minor Geographers, and in the editions of Almeloveen, and of Falconer. There is a French translation of Strabo in 5 vols. 8vo. (1805-1819), by La Porte du Theil, Coray, and Gossellin; the sixteenth and seventeenth books are by Letronne. Strabo was translated into Italian by Ambrosoli, Milan, 1828, 4 vols. 8vo. and 4to. The valuable German translation of Groskurd, in 3 vols. 8vo. (1831-1834), is founded on a corrected text, and is accompanied with critical notes and explanations.

A full account of the editions, translations, and various works in illustration of Strabo is contained in Hoffmann's 'Lexicon Bibliographicum.'

STRADA, or STRADA'NUS, JOHN, was born in the year 1536, of an illustrious family, at Bruges, where he studied the art of painting. He went while very young to Italy, and soon acquired so much proficiency and reputation, as to obtain employment at Florence in the palace of the duke, Cosmo I., and in those of several of the nobility. From Florence he went to Rome, where he devoted himself with the greatest ardour to the study of the antique and the works of Raphael and Michael Angelo. By this means he so much improved his taste, knowledge of composition, and correctness of design, that he was ranked among the most eminent artists of his time; and before he left Rome he was employed in the pope's palace, in conjunction with Daniel da Volterra and Francesco Salviati.

At Naples and other cities of Italy to which he was invited, he executed many considerable works in fresco and in oil; but he fixed his residence in Florence, in which city there are still some fine performances of his; the most celebrated is the Crucifixion, which is a grand composition, with numerous figures larger than life, and near the cross are the Virgin, St. John, and Mary Magdalen.

Though he chiefly painted subjects from sacred history, he was fond of painting animals, hunting parties, and sometimes battles, all of which he executed in a noble style, and with great spirit. It is not possible to reconcile the statements of authors respecting the birth and death of Strada: Sandrart and others say he was born in 1536, and died in 1604, aged 68. This is probably correct. De Piles and Resta say he was born in 1527, and died in 1604, aged 77. The authors of the 'Abrégé de la Vie des Peintres' say that he died at the age of 82; yet they fix his birth in 1536, and his death in 1605, which would make him only 69 years of age.

(Pilkington; Fuseli; Bryan.)

STRADA, FAMIA'NO, born at Rome in 1572, entered the order of the Jesuits, and became professor of rhetoric in the Gregorian college at Rome, where he spent the greater part of his life, and where he died in 1649. He wrote 'Prolusiones,' or Latin essays, upon rhetoric and literature, which were admired at the time. In these essays the author comments upon several of the Roman classical writers, and he introduces his own imitations of their style. He speaks very unfavourably of Tacitus, whom he accuses of malignity, impiety, and want of veracity, though he praises his style. But the work for which Strada is remembered, is entitled 'De Bello Belgico ab Excessu Caroli V. ad Annum 1590,' being a history of the revolt and war of the Netherlands against Spain, which he wrote in Latin, about the same

time as his contemporary Bentivoglio wrote the history of the same war in Italian. Strada brought his narrative down to the year 1590, and the work was continued by two other Jesuits, fathers Dondini and Galluzzi, who wrote the sequel as far as the year 1609: their compositions however are very inferior to Strada's in style. It appears that Strada undertook his work at the desire of the Farnese family, one of whose members, Alessandro Farnese, duke of Parma, became illustrious in the wars of Flanders, as commander of the Spanish armies. The history of Strada is not without merit, though it can hardly be expected to be quite impartial. His rival historian Cardinal Bentivoglio was also biased in favour of Catholic Spain against the Protestant Netherlanders, yet he wrote with considerable freedom, and the work of the Cardinal is generally preferred to that of the Jesuit, but this preference may be partly attributed to the circumstance that Strada's work is written in a dead language.

STRADELLA, ALESSANDRO, a composer much celebrated in musical history, was born at Naples, about the middle of the seventeenth century. His works, most of which are to be found in the British Museum and in the library of Christchurch, Oxford, are chiefly of a miscellaneous kind, consisting of airs, duets, cantatas, madrigals, &c. One oratorio and one opera comprise the whole of his dramatic compositions that Dr. Burney's diligent search enabled him to discover. The former—*San Giovanni Battista*—is highly extolled by the musical historian, who has, in his fourth volume, given a duet from it, as a specimen of the whole, but in the *Fitzwilliam Music* is a quintet from the same of a far superior order. It seems to be agreed that the study of his works contributed largely in forming the taste of many great composers,—of our own Purcell, of Clari, Steffani, A. Scarlatti, and Pergolesi, and this alone is sufficient to bestow on him a lasting reputation.

The personal history of Stradella is so interesting, so romantic when fully narrated, that a brief sketch of it will, we trust, not be thought obtrusive here. It has recently been represented in a dramatic form on the French stage.

He was not handsome, but remarkable for the symmetry of his form, for his wit and polished manners, and these, added to his exquisite style of singing, made his company desirable in the highest circles. At Venice he was engaged by a nobleman to instruct a young lady of high birth, named Hortensia, who, notwithstanding her family rank, submitted to live with the noble Venetian in criminal intimacy. After a time the fascinating qualities and accomplishments of her teacher raised a new flame in her bosom. The passion was mutual, the lovers were married, and fled to Rome, whither they were pursued by two assassins, engaged by the Venetian to punish the inconstancy of his mistress and avenge the injury his pride had sustained. These found the happy couple in the church of San Giovanni Laterano, and they determined to carry their design into execution as the fugitives retired, in a dark evening, at the conclusion of the sacred service. But while waiting the favourable moment, they heard the musician sing, and were so overcome by the charms of his voice and strains, that, confessing to him what had been their object, they declared their determination to abandon it. The intended victims immediately retired to Turin. There they were pursued by two other hired murderers, and though taken under the protection of the Duchess of Savoy, and lodged in her palace, Stradella received three stabs in his breast, and the assassins found a sanctuary in the hotel of the French ambassador, who refused to surrender them. The wounds, though most dangerous, did not prove mortal, and as a year elapsed after the recovery of the sufferer, and no fresh attempt on his life was made, he considered himself secure for the future. But the resentful Venetian only awaited a more certain opportunity for gratifying his unquenchable revenge. Stradella accepted an engagement at Genoa, to compose an opera, whither he went with his wife. Their enemy, informed of this movement, followed them by the agents of his unrelenting revenge, who, rushing into their chamber, stabbed both of them to the heart. This event Walther, in his Lexicon, fixes in the year 1670: but Dr. Burney shows that it must have occurred some years later.

STRAFFORD, THOMAS WENTWORTH, afterwards EARL OF, was born in Chancery-lane, London, on the 13th of April, 1593. He was the eldest son of Sir William Wentworth, of Wentworth Woodhouse, in the county of York, where his family are said to have been settled since the time of the Conquest. His family was one of the most opulent as well as antient of the class known in England under the name of gentry, and had frequently intermarried with the higher aristocracy. The estate which Wentworth inherited from his father was worth 6000*l.* a year, a very large sum at that time, probably equal to more than three times the amount in the present day. (Strafford's *Letters and Dispatches*, vol. ii., pp. 105, 106, folio edition, London, 1739, and Dr. Knowler's *Dedication* prefixed to them.) He received part of his education at St. John's College, Cambridge. In 1611 he married the Lady Margaret Clifford, the eldest daughter of Francis, earl of Cumberland. The accuracy of this date, as that of his first marriage, given by his friend Sir George Radcliffe, appears to be established by a letter dated 11th January, 1611, from Sir Peter Frechevile to his father Sir William Wentworth: although the compilers of his Life in the 'Biographia Britannica' have chosen, in direct opposition to the statement of Radcliffe, the old and intimate friend of Wentworth, to place his marriage after his return from the Continent, towards the end of 1612 (by the old mode of reckoning, according to which the legal year began on the 25th of March, but by the new about the beginning of 1613), instead of in 1611, before his going abroad.

The same letter also shows that he was from his early years of studious and regular habits. He appears to have taken almost as much pains as Cicero recommends for the education of an orator. Sir George Radcliffe informs us that the excellence possessed by him in speaking and writing he attained 'first by reading well-penned authors in French, English, and Latin, and observing their expressions; secondly, by hearing of eloquent men, which he did diligently in their sermons and public speeches; thirdly, by a very great care and industry which he used when he was young in penning his epistles and missives of what subject soever but above all, he had a natural quickness of wit and fancy, with great clearness of judgment, and much practice, without which his other helps of reading and hearing would not have brought him to that great perfection to which he attained. I learned one rule of him,' adds Sir George, 'which I think worthy to be remembered; when he met with a well penned oration or tract upon any subject or question, he framed a speech upon the same argument, inventing and disposing what seemed fit to be said upon that subject before he read the book; then reading the book, compare his own with the author, and note his own defects, and the author's art and fullness; whereby he observed all that was in the author more strictly, and might better judge of his own wants to supply them.' (Strafford's *Let. and Disp.*, vol. ii., p. 435.)

In some of Strafford's earlier letters, particularly those to Sir George Calvert, principal secretary of state in the time of James I., there is, though no marks of profound scholarship, a somewhat pedantic display of trite Latin quotations. From these however, though we may judge so far of the extent of Strafford's scholarship, it would be incorrect to estimate his abilities, for they are mostly confined to his early letters, and, among them, to his letters to courtiers.

Upon his early habits still further light is thrown by some advice which he gives to his nephew Sir William Savile, in a letter dated 'Dublin Castle, 29th September, 1633.' Advising him to 'distrust himself and fortify his youth by the counsel of his more aged friends before he undertakes anything of consequence:' he adds, 'it was the course that I governed myself by after my father's death, with great advantage to myself and affairs, and yet my breeding abroad had shown me more of the world than yours hath done; and I had natural reason like other men, only I confess I did in all things distrust myself, wherein you shall do, as I said, extremely well if you do so too.' (*Let. and Disp.*, vol. i., p. 169.)

The letter from which the above quotation is made contains so much good advice, so well and so weightily expressed, that it may bear a comparison with Burleigh's celebrated 'Advice to his Son:' the resemblance in some passages is striking. With respect to the greater part of this advice, particularly what regards economy and regularity in the management of his private affairs, temperance in drinking, and abstinence from gaming, it was the rule by which Wentworth shaped his own conduct, and to which, according to Radcliffe, he strictly adhered. The part of the advice to which he himself least adhered was that recommending calmness and courtesy of demeanour; for even his most intimate friend Sir George Radcliffe admits that 'he

was naturally exceeding cholerick,' and the actions of his life show that in that particular he was never able thoroughly to subdue nature.

In the same year in which he was married, Wentworth went into France, having previously been knighted. He was accompanied by the Rev. Charles Greenwood, fellow of University College, Oxford, as his 'governor,' or travelling tutor, for whom he entertained the greatest respect and regard to the end of his life. In February, $161\frac{3}{4}$, he returned to England. He was returned and sat for the county of York in the parliament which began April 5th, 1614. Radcliffe's account as to this date, though rejected by the writers in the 'Biographia Britannica,' and Mr. MacDiarmid, is confirmed by Browne Willis's 'Notitia Parliamentaria,' vol. iii., p. 169: 'Co. Ebor. Jo. Saville, kt., Thomas Wentworth, kt. and bart., anno 12 Jac. I., began April 5, 1614, and continued till June 7, and was then dissolved.' During this short parliament, which continued only two months, Wentworth does not appear to have spoken. Mr. Forster, his latest biographer, says that he has examined the Journals, and finds no trace of Wentworth's speaking on either side in the great struggle that was then going on. (*Life of Strafford*, in the *Cabinet Cyclopædia; Lives of Eminent British Statesmen*, vol. ii., p. 197.)

In 1615 Wentworth was appointed to the office of custos rotulorum for the west riding of the county of York, in the room of Sir John Savile; an office of which Savile attempted to deprive him about two years after, through the influence of the favourite, the duke of Buckingham, but without success, though he succeeded afterwards. The result was a feud between Wentworth and the Saviles, the father and son, Sir John Savile the younger, afterwards Lord Savile.

In 1621 Wentworth was again returned to parliament for the county of York; and this time he brought in Sir George Calvert, one of the secretaries of state, along with him. In Michaelmas term, he removed his family from Wentworth Woodhouse to London. He took up his abode in Austin Friars, where in 1622 he had a 'great fever.' When he began to recover, he removed, about July, to Bow, where shortly after his wife the lady Margaret died. On the 24th of February, $162\frac{4}{5}$, he married the lady Arabella Holles, a younger daughter of the earl of Clare, a lady, observes Radcliffe, 'exceeding comely and beautiful, and yet much more lovely in the endowments of her mind.'

Although Wentworth had not taken a very prominent part in the proceedings of parliament, still he was considered to have acted with the party that opposed the court, as appears from the fact of his being, on the eve of the calling together of a new parliament, among the number of those whom Buckingham attempted to disable from serving, by having them pricked sheriffs of their respective counties. In November, 1625, Wentworth was made sheriff of Yorkshire. A passage from one of his letters at this time shows that he was never inclined to go the lengths that some others did in resistance to the royal prerogative. (Strafford's *Letters and Disp.*, vol. i., p. 33.)

In May, 1627, he was committed a prisoner to the Marshalsea by the lords of the council for refusing the royal loan: and about six weeks after, his imprisonment was exchanged for confinement at the town of Dartford in Kent, from which place he was not to go above two miles. About Christmas he was released; and shortly after the third parliament of Charles began, in which Wentworth served as knight for Yorkshire. Wentworth had now resolved to make the court party more aware of the extent of his talents than they yet appeared to be. On the discussion of the general question of grievances, he spoke with an ability and spirit which proved to them that he might turn out such an enemy, that he was worth having as a friend. It has been usual to speak of Wentworth as an apostate. But he never appears to have been at heart on the popular, or rather, the parliamentary side. His whole conduct both before and after he became the king's minister shows that he considered the general movement in modern Europe to be not towards democracy, but towards the establishment of absolute monarchy. The several springs of Wentworth's conduct are now fully laid bare in a manner that they could hardly be to his contemporaries, and in a manner that few men's have ever been to after-ages, by the publication of the two large folio volumes of his 'Letters and Dispatches,' one of the most valuable collections of papers, both in a political and historical point of view, ever made public. In that collection there are two letters (Strafford, *Let. and Disp.* vol. i., pp. 34, 35), to Sir Richard Weston, chancellor of the exchequer, containing very unequivocal overtures, the non acceptance of which at the time would seem to have produced the indignant outbreak of patriotic eloquence above alluded to.

In June, 1628, the parliament ended. In July Sir Thomas Wentworth, having been reconciled to Buckingham, was created Baron Wentworth. The death of Buckingham soon after removed the only obstacle to higher honours. In Michaelmas term he was made Viscount Wentworth, Lord President of the North, and a privy counsellor.

The establishment of the Council of the North originated in the frequent northern rebellions which followed Henry VIII.'s suppression of the lesser monasteries, and extended over the counties of York, Northumberland, Cumberland, Westmoreland, and Durham. The commission, though apparently only one of oyer and terminer, contained a clause authorising the commissioners to hear all causes real and personal, when either of the parties was poor, and decide according to sound discretion. This clause was declared by all the judges to be illegal. James issued a new commission, by which the commissioners were not ordered to inquire 'per sacramentum bonorum et legalium hominum,' or to be controlled by forms of law, but were merely referred to certain secret instructions which were sent down to the council. Against this however the judges had the courage to protest, and to issue prohibitions on demand to the president and council; and the instructions were ordered to be enrolled, that the people might have some chance of knowing them.

Dr. Knowler, the editor of the 'Strafford Papers,' in the adulatory dedication of them to his patron, the grandson of the earl of Strafford, gravely observes that 'Sir Thomas Wentworth, who was a true friend to episcopal government in the church, and to a limited monarchy in the state, could have no reason, when the Petition of Right was granted, to refuse to bear his share of toil and pains in the service of the public, or to withstand the offer of those honours his majesty was graciously pleased to make him, especially when it gave him an opportunity of setting an example of a wise and just and steady administration.' Wentworth's acceptance of this office of president of this council was a flagrant violation of the fundamental principle of the Petition of Right. His career in the office too did not belie the promise of its acceptance. One of his first acts was to declare that he would lay any man by the heels who ventured to sue out a prohibition in the courts at Westminster. (Rushworth, vol. ii., p. 159.) And one of the judges (Vernon), who had the courage to resist these encroachments on the ancient laws of the land, Wentworth tried hard to have removed from his office. (Strafford, *Let. and Disp.*, vol. i., pp. 129, 130.) Indeed, like his friend and coadjutor Laud, Wentworth never let slip an opportunity of expressing his bitter dislike of the interference of the judges and common lawyers with his scheme of governing, not by the laws of England, but according to 'sound discretion.'

In January, 1631, Wentworth was made lord deputy of Ireland. The principle on which he set about governing there was in substance the same as that of his government in the presidency of York. 'These lawyers,' he writes to the lord marshal, 'would monopolise to themselves all judicature, as if no honour or justice could be rightly administered but under one of their bencher's gowns.' (Strafford, *Let. and Disp.*, vol. i., p. 223.) And he adds, a line or two after, 'Therefore if your lordship's judgment approve of my reasons, I beseech you assist me therein, or rather the king's service, and I shall be answerable with my head.'

It is remarkable how frequently he alludes to this last as the test of the soundness of the policy of his measures. They were in the end so tested, and being found wanting, he was taken at his word; he was called upon to pay, and paid the forfeit. One of the principal means by which Wentworth sought to squeeze money out of the people of Ireland was by holding a parliament.

Wentworth's political economy was not very sound, yet he saw far enough to discover that to enrich the king, the way was, to begin by enriching the people. 'For this is a ground,' he says, 'I take with me, that to serve your majesty completely well in Ireland we must not only endeavour to enrich *them*, but make sure still to hold them dependent upon the crown, and not able to subsist without

us. (Strafford's *Let. and Disp.*, vol. i., p. 93.) But the plan he proposed does not seem certainly very well adapted for enriching the people. 'Which will be effected,' he proceeds, 'by wholly laying aside the manufacture of wools into cloth or stuff there, and by furnishing them from this kingdom; and then making your majesty sole merchant of all salts on that side; for thus shall they not only have their clothing, the improvement of all their native commodities (which are principally preserved by salt), and their victual itself from hence (strong ties and enforcements upon their allegiance and obedience to your majesty); but a means found, I trust, much to advance your majesty's revenue upon salt, and to improve your customs. The wools there grown, and the cloths there worn, thus paying double duties to your crown in both kingdoms; and the salt outward here, both inward and outward there.' He thus sums up the advantages of the measures proposed:—'Holding them from the manufacture of wool (which, unless otherwise directed, I shall by all means discourage), and then enforcing them to fetch their clothing from thence, and to take their salt from the king (being that which preserves and gives value to all their native staple commodities), how can they depart from us without nakedness and beggary? Which in itself is so weighty a consideration, as a small profit should not bear it down.' (*Let. and Disp.*, vol i., p. 193.)

In one particular he did benefit Ireland. At his own risk he imported and sowed a quantity of superior flax-seed. The first crop having succeeded, he next year laid out 1000*l.* on the undertaking, set up a number of looms, procuring workmen from France and Flanders, and sent a ship to Spain freighted with linen at his own risk. Thus began the linen manufacture of Ireland, which in some measure verified Wentworth's prediction that it would greatly benefit that country. (Strafford, *Let. and Disp*, vol. i., p. 473.)

Wentworth appears to have been of very infirm health, which, taken with the general course of his education and his position in society, will in part account for the acerbity and irritability of temper, and the impatience of any opposition to his will, which throughout his career involved him in so many personal quarrels. The number of powerful personal enemies which Wentworth thus arrayed against himself appears to us to be a proof of the want of real political talent of a high order. A really wise politician, such as Oliver Cromwell for example, does not raise up such a host of powerful personal enemies. Laud gives a good hint about this in one of his letters. 'And yet, my lord,' he says, 'if you could find a way to do all these great services and decline these storms, I think it would be excellent well thought on.' (Strafford, *Let. and Disp.*, vol. i., p. 479.)

In 1639 Charles raised Wentworth to the dignity of an earl, which he had in vain solicited formerly. He was created earl of Strafford and baron of Raby, and invested with the title of lord-lieutenant, or lieutenant-general of Ireland—a title which had not been borne since the time of Essex.

In 1640 the earl of Northumberland being attacked by severe illness, the king appointed Strafford in his place, to the command of the army against the Scots. He does not appear to have performed anything here to make good either his own high pretensions or the character for valour given him by some writers. Of his impeachment at the opening of the Long Parliament, Clarendon gives the following account:—'It was about three of the clock in the afternoon, when the Earl of Strafford (being infirm and not well disposed in health, and so not having stirred out of his house that morning), hearing that both houses still sate, thought fit to go thither. It was believed by some (upon what ground was never clear enough) that he made that haste there to accuse the Lord Say, and some others, of having induced the Scots to invade the kingdom; but he was scarce entered into the house of peers, when the message from the House of Commons was called in, and when Mr. Pym at the bar, and in the name of all the Commons of England, impeached Thomas, earl of Strafford (with the addition of all his other titles), of high treason.'

In the article PYM we have shortly adverted to the trial of the Earl of Strafford for high treason. To the remarks made there we may add that, though it was not to be supposed or expected that the Statute of Treasons of Edward III. (25 Edward III., st. 5, c. 2), being made to protect the king, not the subject, would provide specially for the punishment of such attempts as those of Strafford; it does nevertheless appear that Strafford was punishable for having become the instrument for administering the government of the Council of the North, carried on in direct violation of the Petition of Right, which during the time of Strafford's being president of that council was the law of the land. However the Commons changed their course and introduced a bill of attainder, which was passed on the 21st of April, in the Commons, and soon after in the Lords. The king with tears in his eyes and other demonstrations of weakness characteristic of him signed a commission for giving the royal assent to the bill, and then made some feeble and unavailing efforts to save the life of his obnoxious minister. 'The resort to the bill of attainder,' observes Mr. Forster (*Life of Strafford*, p. 404), 'arose from no failure of the impeachment, as has been frequently alleged, but because in the course of that impeachment circumstances arose which suggested to the great leader of the popular cause the greater safety of fixing this case upon wider grounds. Without stretching to the slightest extent the boundaries of any statute, they thought it better at once to bring Strafford's treason to the condemnation of the sources of all law.'

Strafford was beheaded on Tower Hill on the 12th of May, 1641. In his walk from the Tower to the place of execution his step and manner are described by Rushworth as being those of 'a general marching at the head of an army, to breathe victory, rather than those of a condemned man, to undergo the sentence of death.' Within a few weeks after his death, the parliament mitigated the penalties of their sentence to his children. In the succeeding reign, the attainder was reversed, and his son was restored to the earldom.

STRAIGHT, STRAIGHT LINE, PLANE. There is no occasion to define a straight line as matter of information; so that we have here only to consider the definitions which have been given and their relative merits, taking them as attempts to produce a mathematical description of straightness.

There are three attempts at definition of a straight line; by Plato (or one of his immediate school), by Archimedes (as is said), and by Euclid. The moderns have repeated these various forms, but have not, to our knowledge, ever succeeded in producing a definition entirely new which did not contain the defects of one or other of the three just mentioned.

The Platonic definition, according to Proclus, is as follows:—'A straight line is that of which the middle parts hide (ἐπιπροσθεῖ) the extremities;' a physical definition, owing its truth to the circumstance of the rays of light proceeding in straight lines, and involving the notion of straightness as a part of its own explanation. This definition has been little if at all used by geometrical writers.

Archimedes defines a straight line as the shortest distance between two points, or at least this definition is often attributed to him, but not correctly. It is one of his postulates in the book on the Sphere and Cylinder, that of all lines drawn between two points the least is that which is straight: but he is too well judging a geometer to assign such a property as a definition. The Arabs substituted the shortest-distance description for the definition in Euclid, and accordingly our earlier editions of Euclid do the same; nor was this flaw removed until 1505, when Zamberti translated Euclid from the Greek. It has been often supposed that this shortest-distance definition is good as a definition, though not proper for a pupil in geometry, an opinion from which we must dissent: for how is it known to those who are yet to learn what a straight line is, whether there can be a shortest distance? That is, how is it known that there are not many distances between two points, on different lines, which are severally shorter than any other distance, and equal to one another? The answer is, no doubt, that the mind has a perfect conception of the impossibility of such a thing; and the rejoinder is—yes, because the mind has a perfect conception of a straight line: that is to say, the definition is only saved from causing confusion by its own uselessness. Again, the supposition that measurement of distances on all manner of curves is to be a preliminary to one of the definitions of a science which treats no curve but the circle, and does not succeed, by reasons of certain limitations of process, in measuring distance even on that one, is an incongruity.

Euclid defines a straight line to be that which lies evenly (ἐξ ἴσου κεῖται) between its extreme points. The words ἐξ

ἴσου have been translated *ex æquo* by Barocius, *ex æquali* by Zamberti, *equally* by Billingsley (taking some of the oldest translations as specimens). The definition wants precision, but the meaning is obvious. Two points being given, the surrounding space may be viewed in all manner of relations to those two points, as above or below, right or left, &c. The straight line which joins the two points is that which is not more related to one of these notions than to any other; and throughout its whole length takes an even course, without a possibility of being claimed, so to speak, by any one of the surrounding parts of space rather than by any other.

In making such a definition Euclid is well aware that he cannot rest any conclusion upon it, and that in the postulate that two straight lines cannot inclose a space lies all his power of producing a theorem. Why then, it may be asked, does he introduce a definition at all? Why not give the reader to understand that a straight line is a notion universally understood and incapable of definition in simpler terms? To these questions the answer may be twofold. In the first place, he is not answerable for the genius of any language but his own, and it is very possible that to a Greek commencing geometry, εὐθεῖα might be a hard word, and ἐξ ἴσου κεῖται a real explanation; in which case his definition is defensible until it can be shown that he might have chosen a better one. We are not to judge of the force of the last-quoted words from the *ex æquo* of the middle Latin, or the *evenly* or *equally* of the English. Secondly, he is evidently, in his first definitions, recalling, and not instilling, notions: he is proceeding with his reader as by words to which both attach a conception, and he tries these words for use by ascertaining that both parties agree on such circumlocution as can be substituted for them.

The greatest defect of Euclid's definition, since it applies even to the view just taken of its intent, is the want of words signifying that ἐξ ἴσου refers equally to *all* adjoining parts of space: Euclid is thinking too much of a plane before he has defined a plane. Suppose, for instance, a sphere, and that lines on a sphere only are contemplated: the line which joins two points ἐξ ἴσου with reference to all adjacent parts of that sphere is not a straight line, but an arc of a great circle.

Is it possible, taking such allowances as Euclid sanctions in the use of figure, to give what shall be, whether difficult or not difficult, capable of use or not capable, a just definition of a straight line? We think it is, as follows:—The Greek geometer implicitly allows (i. 4) a TRANSLATION of figure without change of form or properties: from this, by first defining the plane, a definition of the straight line may be proposed, which we bring forward, not for any value which it has, but because the stipulations of geometry are better understood by consideration of cases proposed for acceptance or rejection, than by any other method.

1. Let two points (A and B) be said to be at the same *distance* from a third (C), when A and C being joined by *any* line, the line CA can be translated, C remaining fixed, so that A shall be brought to coincide with B.

2. A plane is a surface any point of which is equally distant from two given points.

3. A straight line is the intersection of two planes.

In the debates of the normal school, which were taken down in shorthand, and published in 1800, is a discussion on this subject. Lagrange presiding, Fourier, then one of the pupils, proposed the preceding second and third definitions, but without assigning a definition of equidistance independently of the straight line. He also proposed as the definition of a straight line the locus of a point which is equidistant from three given points; which is faulty, inasmuch as the three given points should not be in one straight line, which cannot be supposed until the straight line is defined. Lagrange admitted the rigor of the definition, but considered that it failed in presenting a sensible image of the thing defined. Another of the pupils however insisted that the idea of distance involved that of a straight line, which is true of distance as a quantity, though not necessarily so of equidistance as a relation.

Colonel Thompson proposes to define a straight line as one which being turned about its extreme points suffers no change of place. Lagrange, in the debate above alluded to, suggested the same notion. This definition, we think, offers the most tangible illustration of that of Euclid. Let the two extremities of the intended straight line be situated in a solid; and let them remain fixed in space while the solid takes such motion as, under that condition, it is capable of. The straight line, the line which lies ἐξ ἴσου with regard to the extreme points, then remains fixed. For if any part of it moved, there would be in every position a relation to adjoining parts of space, which would be in a state of continual change. The connexion between this definition by rotation and that of Euclid might require more development to render it as clear as possible: but we think the student's own reflection will lead him to make it satisfactorily. But whatever may be thought of the endeavour to exercise the discrimination of which geometry points out the possibility by framing or arguing on definitions, we do not remember to have seen one so well calculated for the mere beginner as the following:—'A straight line is a straight line.'

The postulates relative to a straight line demanded by Euclid (we do not speak of his translators) are: 1. That such a line can be drawn from any one point to any other. 2. That when terminated, it can be lengthened indefinitely. 3. That two such lines cannot inclose (μὴ περιέχειν) a space. It is also tacitly assumed that every part of a straight line is a straight line: that every straight line, infinitely produced, divides a plane in which it lies into two parts, and will be cut by any line drawn from a point on one side of it to a point on the other. It might also have been assumed that two straight lines which coincide in two points, coincide when produced beyond those points; but here Euclid has preferred to assume that all right angles are equal. [RIGHT ANGLE.]

The definition which Euclid gives of a plane, is that of a surface which lies evenly between its bounding straight lines. To this definition there is the serious objection that though a plane may be as easily conceived as a straight line, yet it is actually capable of definition by a straight line. For a plane is the surface any two points of which can be joined by a straight line which lies wholly on the surface. Neither this definition (nor Euclid's) precludes the necessity of a postulate demanding the possibility of drawing a plane through any straight line. Objections might be made to the first part of Euclid's eleventh book, which would require for their answer that another postulate should be granted, similar to that required for a straight line, namely, that if two planes coincide in any portion of surface, they coincide altogether. Euclid does in fact assume a postulate which is not expressly laid down, namely, that a finite straight line can be produced in every plane in which it lies, but we think it may be fairly doubted whether the first three propositions of the book in question are as perfect as they might be made.

STRAIN and STRESS. [MATERIALS, STRENGTH OF.]

STRAIN. [SPRAIN.]

STRALSUND, one of the three governments into which the Prussian province of Pomerania is divided, consists of what was formerly Swedish Pomerania, with the island of Rügen and some other islands: it is bounded on the north by the Baltic, on the east and south by the government of Stettin, and on the west by Mecklenburg-Schwerin. It is almost entirely surrounded by water, having the Baltic on the north, and being divided from Mecklenburg by the navigable rivers Trebel and Reckenitz, and by the Peene from the government of Stettin. This is the smallest of the three governments of Pomerania: the area is 1660 square miles, with a population of between 160,000 and 170,000 inhabitants; it is divided into four circles. The soil is a heavy loam and black mould, far superior in fertility to the light sandy soils of the governments of Stettin and Cöslin; the products are similar, consisting of wheat, barley, and peas; flax and tobacco are likewise cultivated. The breed of horned cattle is not numerous, for want of sufficient pasture; sheep and hogs however are in great numbers, and there are immense flocks of geese. There are no manufactures of any importance. Those of linens and woollens are insufficient, and produce only coarse articles. The manufactories of tobacco and the brandy distilleries are very considerable. The commerce of this government is very important and lucrative; the exports are chiefly flour, malt (5000 lasts annually), and, above all, corn, which constitutes a third, and sometimes the half of the exports, and for the most part goes to Sweden. The fisheries are likewise very profitable.

STRALSUND, the capital of the government, is situated in 54° 15′ N. lat. and 13° 8′ E. long., in an extensive low sandy plain, bounded on one side by the Strait of Gellen, which separates the island of Rügen from the continent;

and on the other sides by great lakes and marshes, so that it is connected with the continent only by bridges. The celebrated fortifications have been razed, and the ramparts converted into public walks. It is rather a gloomy place, the houses being built in the old style, the streets are irregular, and the squares and market-places inconsiderable: it is however clean and well paved. There are four Protestant churches and one Roman Catholic chapel. The three principal churches are built in the Gothic style, and contain many fine paintings. The prospect from the lofty steeple of St. Mary's is very extensive. Among the other public buildings worthy of notice are—the government-house, the town-house, with a noble hall, and a considerable public library, the gymnasium, with a large library and cabinet of medals, the mint, the arsenal, and the water-works by which the city is supplied with good water. The principal public institutions are—the gymnasium, the normal school for training schoolmasters, a school for soldiers' children, two schools of industry, besides many other schools: an orphan-house, a lunatic asylum, and various other charitable establishments. The manufactures are of various kinds, chiefly woollens, linen, sugar, starch, soap, candles, tobacco, leather, looking-glasses, household furniture, and playing-cards. There are likewise brandy distilleries and oil-mills. The trade of this city is very considerable, being at least one-third of the foreign commerce of the whole province. The harbour is spacious and safe, and deep enough for ships drawing 15 feet water. The northern outlet by the Gellen Strait has become gradually narrower, and Hassel says it is with difficulty kept open, but that the eastern channel has become broader. Stralsund was built about the year 1209, and joined the Hanseatic League, during its union with which powerful confederacy it had a very extensive export trade in wool and herrings to remote countries. At present the chief exports are malt, corn, and wool. The town has sustained several sieges; the most remarkable of which was in 1628, when Wallenstein vowed that 'he would make himself master of it, even though it were fastened by chains to Heaven,' but he was obliged to raise the siege after suffering considerable loss. In 1678 it was taken after a destructive bombardment by the great elector Frederic William of Brandenburg; and in 1715 by Frederick William I., king of Prussia, in alliance with Russia, Denmark, and Saxony against Sweden. The heroic Schill fell here in 1809. By the treaty of Kiel in 1810, it was ceded with all Swedish Pomerania to Denmark, and again ceded by Denmark in 1815 to Prussia.

(Müller, *Handbuch*; Heidemann, *Wörterbuch*; Hassel; Stein; Cannabich; Hörschelmann, &c.)

STRAMO'NIUM [DATURA.]

STRANGE, SIR ROBERT, a descendant of the family of Strange of Balcasky, in the county of Fife, was born at Pomona, one of the Orkney Isles, on the 14th of July, 1721. After successively adopting and abandoning the study of the law and the pursuit of a seafaring life, he was apprenticed to a drawing master. He had studied for a considerable time, when he joined the forces of the Pretender, and was appointed a lieutenant in the Life-Guards, a step he is said to have taken with a view of obtaining the hand of Miss Isabella Lumisden, a lady whom he married in 1747. After the battle of Culloden he sought refuge in the Highlands, where he suffered the severest privations. Subsequently he ventured to Edinburgh, where he subsisted upon the produce of a sale of his drawings of the chiefs of the rebellion, which he privately disposed of at a guinea each. After his marriage he went abroad, and at Rouen obtained an honorary prize for design, when he proceeded to Paris, where he studied engraving under the celebrated Le Bas, from whom he learned the use of the dry point, of which he made such successful use in his own plates. In 1751 Strange settled in London, and soon established a high reputation as an historical engraver, of which class he is considered to be the first in the English school.

In 1760 he again went abroad, and executed plates after pictures by many of the greatest of the old masters, and was made a member of the academies of Rome, Florence, Bologna, Parma, and Paris. On his return to England, he was received with every mark of distinction, and in 1787 was knighted. He died on the 5th of July, 1792. He left a widow, three sons and one daughter, amply provided for by the fruits of his industry and ability. Strange is the only Englishman whose portrait is introduced in the painting in the Vatican of 'The Progress of Engraving.' Force, vigour, clearness, and precision are the prevailing characteristics of his style, nor is he less noted for the careful distinction which he makes in his plates between the texture of the various materials represented. He was the author of an unpublished treatise entitled 'The History of the Progress of Engraving,' to which he added impressions of his principal plates and a portrait of himself. The following is a list of his most important works:—St Cecilia, after Raffaelle; the Virgin and Infant Christ, with Mary Magdalen, St. Jerome, and two Angels, after Correggio; Mary Magdalen, the Death of Cleopatra, Fortune flying over a Globe, Venus attended by the Graces, and Joseph and Potiphar's Wife, after Guido; Christ appearing to the Virgin after his Resurrection, Abraham expelling Hagar, Esther and Ahasuerus, and the Death of Dido, after Guercino; Venus and Adonis, Venus reclining, and Danäe, after Titian; Romulus and Remus, and Cæsar repudiating Pompeia, after Pietro da Cortona; Sappho consecrating her Lyre, after Carlo Dolci; the Martyrdom of St. Agnes, after Domenichino; Belisarius, after Salvator Rosa, the Virgin with St. Catherine and Angels contemplating the Infant Jesus, after Carlo Maratti; the Choice of Hercules, after Nicholas Poussin; and the Return from Market, after Philip Wouvermans. Amongst his portrait engravings may be particularly mentioned the Children of Charles I., and Queen Henrietta Maria, with the Prince of Wales, and Duke of York, after Vandyke. (*Memoir of Sir Robert Strange*; Aikin's *General Biography*.)

STRANRAER [WIGTONSHIRE.]

STRASBOURG (in German, *Strassburg*), a town in France, capital of the department of Bas Rhin, 243 miles east of Paris in a direct line, or 294 miles by the road through Château-Thierry, Châlons-sur-Marne, St. Dizier, Bar-le-Duc, Toul, Nancy, Lunéville, and Saverne; in 35′ N. lat. and 7° 47′ E. long.

Strasbourg was known to the Romans by the name of Argentoratum or Argentoratus. It is first mentioned by Ptolemy, who calls it a town of the Vangiones: but this is an error, as it really belonged to the Triboces. It was in the Roman province of Germania Prima or Superior (the First or Upper Germany); and it was near this town that Julian, while he held the command in Gaul, as Cæsar, defeated the Allemans under their king Chnodomar (A.D. 357). At a subsequent period it appears to have fallen into the hands of the Allemans, from whom it was taken by Clovis and the Franks. It was afterwards included in Lotharingia, or the kingdom of Lothaire; and in the tenth century was incorporated with the German empire. It was during these changes, perhaps in the sixth century, that it exchanged its antient name of Argentoratum for that of Stratae-burgus, modified into Stratzburg and Strassburg. It was in the landgraviate of Alsace; but having obtained the privileges of a free city, it increased in prosperity. In A.D. 1349 it suffered from a fearful mortality, which was attributed to the Jews, 200 of whom were in consequence burned. The principles of the Reformation were early introduced, and gained such ground, that, though checked by the emperor Charles V., the Protestants obtained possession of several of the churches. In 1681 Strasbourg surrendered to Louis XIV., who had previously gained possession of Alsace. Louis enlarged the circuit of the walls, and so improved the defences as to render it one of the strongest fortresses in Europe. It has remained ever since that period incorporated with France.

The town stands in a flat situation in the valley of the Rhine, which valley has here a considerable breadth, extending from the mountains of the Schwarzwald or Black Forest, to the Vosges. The form of the town is irregular. Its greatest length is from east to west, nearly two miles; its greatest breadth about one; and its circuit five or six. It is surrounded by a wall strengthened by bastions, ditches, and outworks, and has at its eastern extremity a citadel, with five bastions, constructed by Vauban, the outworks of which extend as far as the Rhine. This river flows a little to the east of Strasbourg, and is crossed here by the bridge of boats of Kehl, a fortress in Baden, on the right bank. The entrance into the city is by seven gates, two on the north side, one on the north-west, two on the west, and two on the south.

The river Ill flows through the town in a north-north-east direction. After it enters the town it is divided into several branches, which reunite before it quits the place. The principal arm, which bears the name of the Bruche, is

navigable, and receives on its right bank the canal of the Rhine, by means of which there is ready communication with that river. Another arm, which has the name of Tanners' ditch (fossé des Tanneurs), is much used for supplying tan yards and other manufacturing establishments. The river can be made to inundate the neighbourhood, by means of a sluice at the point where it enters the town. There are a great number of bridges, some of stone, others of wood. Some of the branches of the Ill, judging from their direction, have been the ditches dug to encircle and defend the town before it had attained its present extent.

Dr. Dibdin, who visited Strasbourg in July, 1818, thus describes its general appearance:—'The city of Strasbourg encloses within its walls a population of about fifty thousand. I suspect however that in former times its population was more numerous. At the present moment there are about two hundred and fifty streets, great and small, including squares and alleys. The main streets, upon the whole, are neither wide nor narrow; but to a stranger they have a very singular appearance, from the windows of almost every house being covered on the outside with iron bars arranged after divers fashions. This gives them a very prison-like effect, and is far from being ornamental, as it is sometimes intended to be. The glazing of the windows is also frequently very curious. In general the panes of glass are small and circular, being confined in leaden casements. The number of houses in Strasbourg is estimated at three thousand five hundred. There are not fewer than forty-seven bridges in the interior of the town. . . . . . The houses are generally lofty, and the roofs contain two or three tiers of open windows, garret fashioned, which gives them a picturesque appearance; but which, I learn, were constructed as granaries, to hold flour for the support of the inhabitants when the city should sustain a long and rigorous siege.' (*A Bibliographical, &c. Tour in France and Germany*, by the Rev. T. F. Dibdin, D.D.) From another authority we learn that the streets amount to more than two hundred and sixty, and are for the most part crooked and narrow; that there are several public squares, of which the principal is the parade, planted with trees, adjacent to the citadel: that the houses are for the most part built of stone, and that the antient houses in the German style are being gradually replaced by others of modern construction. (*Dictionnaire Géographique Universel*, Paris, 1832.)

The principal public building is the cathedral of Notre Dame, a Gothic edifice of singular beauty. The nave and choir have a total length of 355 English feet, of which 244 belong to the nave: the width of the nave, with its side aisles, is 132 feet, but the height of the nave is only 72 feet. Nine massive clustered columns, the larger of them having a circumference of 72 feet, the smaller of 30, support the roof on each side. The choir has no side aisles: it is 67 feet wide, and much lower than the nave. The sides have been covered most incongruously with a number of pillars and pilasters of Grecian architecture. There are two chapels, those of St Laurent and St. Catherine, besides that of Le Saint Sepulchre, which is the crypt; and twelve altars, of which the two principal are in the chapels of St. Laurent and St. Catherine. The windows are adorned with abundance of stained glass; but generally of a sombre tint, and producing a gloomy effect, with the exception of the circular or marygold window of the west front, which is brighter. There are a stone pulpit, unequalled for the richness, variety, and elaborateness of its sculptured ornaments; an organ of admirable power and softness; and a remarkable astronomical clock, formerly accounted one of the wonders of the place for the variety and skilfulness of its mechanical contrivances, and the elaborateness of its ornaments, but now much out of order, and useless. The most striking part of the cathedral is its western front, a masterpiece of enriched architecture, decidedly superior, in the opinion of some critics, to our own cathedrals of York, Lincoln, or Peterborough. It is divided into three compartments by its ornamented buttresses (two of which are at the angles, and two in the centre); and each compartment again into three portions by horizontal bands. The lower portions are occupied by three porches, that in the centre being the most ornamented and the loftiest. In the second or middle portion the most striking feature is the enormous circular or marygold window; and three equestrian statues of the Frankish kings Clovis and Dagobert, and the German emperor Rudolph of Hapsburgh, in canopied openings in the buttresses. A fourth canopied opening is unoccupied. The third or upper portion has some beautiful windows; and the northernmost of the three compartments is surmounted by a tower and spire, having at each of the four corners of the tower a spiral staircase enclosed in open work. The spire rises to the height of 500, or perhaps 530 English feet. The cathedral was commenced near the close of the thirteenth century; and the external structure, as it now appears, was completed about the beginning of the fifteenth. It was much injured during the Revolution: two hundred and thirty five statues were taken down from different parts of the building to be demolished, and only sixty five of them have been preserved.

This celebrated church was built at various periods: the choir is said to be of as early a date as the age of Pepin le Bref and Charlemagne; the nave was commenced in the early part of the eleventh century by the bishop, Werner of Hapsburg; and the west front and the tower were planned by Erwin or Ervin of Steinbach, an architect of the thirteenth and fourteenth centuries. He superintended the erection of these parts until his death, A.D. 1318. The tower was not finished till the middle of the fifteenth century. The architect who completed it was John Hültz, a native of Cologne.

Of the subordinate churches (Strasbourg possesses fifteen in all, seven Catholic, seven Lutheran, and one Calvinist, beside a Jews' synagogue), the most remarkable for size and antiquity is that of St Thomas, belonging to the Lutherans. Some portions are perhaps more antient than the cathedral, but the outside is a tasteless jumble of various styles, and the inside has been trimmed up and smartened in the most tasteless and incongruous style. It has several antient monuments: a much vaunted but really tasteless and absurd mausoleum of Le Maréchal de Saxe; and modest unassuming monuments of Schoepflin, Oberlin the classical scholar, and Koch the historian. The churches of St. Etienne and St. Martin are antient: Le Temple Neuf has some lancet-shaped stained glass windows of exquisite beauty. The public library is attached to this church, and some of the books are kept in the church itself.

The other principal buildings are the antient castle, with a terrace-walk on the Bruche; the office of the prefect; the town-hall; the custom-house; the court of justice; the public granary; and the theatre, adorned with an Ionic colonnade, and having a spacious and elegant interior. There are several public walks; among which are the promenade of Le Broglie, which skirts the Tanners' ditch, the ramparts, which are planted with trees, the esplanade in front of the citadel, the suburb of Robertsau or Rupersau on the north side of the town, and the islands of the Rhine, on one of which a monument has been erected to the memory of Desaix.

The population of Strasbourg, in 1831, was 45,642 for the town, or 49,712 for the whole commune; in 1836 it was 57,885 for the commune. The trade of the town is very considerable: its manufactures include jewellery, metal buttons, starch, alum, oil of vitriol, white-lead, steel, cutlery, pins, combs, cast-iron goods, earthenware, porcelain, enamel, soap, oil from seeds, succory or chiccory, morocco and other leather, straw and other hats, woollen and cotton stuffs, cotton yarn, hosiery, printed flannels, sail cloth, oilcloth, thread, carpeting, furs, paper-hangings, playing-cards, &c. There are bleach-grounds, dye-houses, rope-walks, tan-yards, breweries, printing-offices, plaster-kilns, tile-yards, an iron-forge, a type-foundry, a sugar refining-house, a royal snuff-manufactory, &c. The publication and sale of books is an important branch of industry at Strasbourg. There is a considerable trade carried on with other parts of France, and with Holland, Germany, Switzerland, and Italy, by means of the Rhine and the Ill and their connected navigation; and much business is done in the produce of the surrounding territory, which includes corn, wine, tobacco, madder, hemp, hops, saffron, &c. There are four important yearly fairs much frequented by the Germans.

Before the Revolution there was at Strasbourg a Protestant University, with four faculties. It was established by the town council or senate in 1538 as a gymnasium or public school: this was changed into an academy, with the power of granting degrees in arts, by the emperor Maximilian II., A.D. 1566; and was raised to the rank of a university by the emperor Ferdinand II., A.D. 1621. There are now two seminaries for the Roman Catholic priesthood; a Protestant seminary, and a gymnasium or college; a faculty of theology of the Lutheran body; and

faculties of law, medicine, science, and literature; a normal class for training schoolmasters; a school of midwifery and a school of medicine; a drawing-school; a royal college, with a philosophical apparatus; a museum, a cabinet of natural history, a cabinet of anatomy, an observatory, a botanic garden, where lectures are delivered, and a public library of above 50,000 volumes; an academic society, which confers premiums; a society of agriculture, sciences, and arts; a Protestant Bible society; a society for the relief of young persons discharged from prison who have shown symptoms of penitence; public baths; a noble arsenal, including a school of artillery and a cannon-foundry; vast barracks for cavalry, infantry, and artillery; a mont de piété or loan society; three hospitals, including one for orphans and one for foundlings; two military hospitals; a military prison, a gaol, and a house of correction, to which is attached a lunatic asylum; a number of government offices for fiscal, judicial, and administrative purposes; a mint, and a government stud (*dépôt des étalons*). It is the capital of the department; the seat of a bishop, who is a suffragan of the archbishop of Besançon, and whose diocese comprehends the departments of Bas Rhin and Haut Rhin; the seat of a Lutheran consistory, and of an académie universitaire, and the head-quarters of the fifth military division, which comprehends the two departments of Bas Rhin and Haut Rhin.

Strasbourg was the birthplace of Mentel, one of the fathers of the art of printing; of General Kleber, who was left by Bonaparte in command of the French army in Egypt; of the classical scholars Brunck, Oberlin, and Schweighaeuser; and of the philanthropist Oberlin, pastor of the Ban de la Roche, and brother of the scholar. The population of the town is partly Protestant and partly Roman Catholic. German may be considered as the native tongue of the inhabitants; but among the educated classes both German and French are used.

The arrondissement of Strasbourg has an area of 546 square miles, and comprehends 162 communes, with a population, in 1831, of 205,029, and, in 1836, of 218,839. It is divided into twelve cantons or districts, each under a justice of the peace. The bishopric dates from the fourth century: the bishop had formerly the title of prince of the empire, and was a suffragan of the archbishop of Mainz or Mayence.

STRATE'GY (from the Greek στρατηγία, which may be translated 'generalship') is, properly, the science of combining and employing the means which the different branches of the art of war afford for the purpose of forming projects of operations and of directing great military movements: it was formerly distinguished from the art of making dispositions, and of manœuvring, when in the presence of the enemy; but military writers now, in general, comprehend all these subjects under the denominations of grand and elementary tactics. [TACTICS.]

Strategy consists chiefly in making choice of convenient bases (fortified places or strong positions) in order to place there in security the military establishments of an army; such as the barracks, hospitals, and magazines of ammunition and provisions, previously to commencing offensive operations, or in contemplation of the army being compelled to act on the defensive. In the former case, it may be necessary to decide on undertaking the siege of some fortress on a frontier, for the purpose of holding the neighbouring district in subjection, and commanding the roads by which it may be thought convenient to penetrate into the enemy's country, or by which the provisions and warlike stores may be brought up to the immediate seat of the war. In the latter case, choice is to be made of positions strong by nature, or which may be made so by art, in order that the army may be enabled to dispute the ground gradually, to harass the enemy by frequent skirmishes, or to prevent him from receiving supplies by intercepting his convoys on the roads.

Thus, after the battle of Vittoria (1813) the allied British and Spanish armies being at a great distance from the original base of operations in Portugal, and it being intended to carry the war into France, Lord Wellington undertook to besiege St Sebastian and to blockade Pampeluna, in order, by the possession of those places, to have secure stations for his recruits and magazines while the army advanced into the mountainous districts between St. Jean Pied-de-Port and the sea. On the other hand, the conviction, in 1809, that the British army would be compelled to act entirely on the defensive, induced the English general to take measures for a retreat into Portugal, and to commence, many months before the retreat took place, two chains of strong redoubts on the north of Lisbon, in the expectation of being able there to resist effectually the very superior forces of the enemy.

The project formed by Marshal Soult, in 1813, in opposition to that of Lord Wellington, affords also a good illustration of the nature of strategical operations. The French general decided to advance towards Pampeluna in the hope of being able to succour that place, and afterwards to unite his army with that of Suchet in Aragon: he expected also to command the road along the Spanish frontier, by which he might have got to the rear of the allies in a fertile country, where his army could have found subsistence. (Napier, vol. vi.) This project failing, and the battles of the Pyrenees having forced the French army to act on the defensive, Marshal Soult took measures for protracting the war to the utmost.

In the defence of an extensive territory, since it is generally impossible to cover the whole, the principles of sound strategy indicate that the army should be kept in force on a few of the most important positions. By securing these, the designs of the enemy may be more effectually frustrated than if it were attempted to occupy every post in the country; for the different divisions of the army being in the latter case weak and ill supported, they are liable to be cut off in detail, whereas the difficulty of dislodging a large body of troops from one strongly intrenched position may deter the enemy from attempting it: at the same time the occupation of that position by the defending army may paralyze his movements by rendering it dangerous for him to leave in his rear a force which might prevent him from drawing supplies from his magazines. The evils attending the dissemination of troops over a great extent of country are strongly exemplified in the surprise of the Austrians by Marshal Turenne. The French general caused the several corps of his army to be drawn together towards Befort in such a manner as not to excite notice; and from thence suddenly penetrating into Alsace, in the midst of the enemy's quarters, he defeated the troops before they had time to unite.

STRATFORD-UPON-AVON, a municipal but not a parliamentary borough in the Stratford division of Barlichway hundred, in the county of Warwick, 96 miles northwest of the General Post-office, London, by Uxbridge, Beaconsfield, Wycombe, Oxford, Woodstock, and Shipston-on-Stour.

Stratford was a place of some consequence three centuries before the Conquest. The manor was included in the possessions of the bishopric of Worcester, the holders of which obtained charters from the earlier kings of the Plantagenet family for a market and five yearly fairs. In the reign of Edward VI. the manor came by exchange to Dudley, earl of Warwick and duke of Northumberland, and has since then passed through various hands. There was some skirmishing here in the great civil war (A.D. 1642-3). But the principal interest of the town is derived from its having been the birth-place of Shakspere (A.D. 1564), and the place to which he retired in his maturer years, and where he died (A.D. 1616). [SHAKSPERE, WILLIAM.] In A.D. 1769 a festival termed 'the Jubilee' was celebrated at Stratford, in honour of Shakspere, under the direction of Garrick. The festival was attended by a great concourse of persons of rank; but the incongruity of many of the arrangements provoked the satire of some of the wits of the day. A triennial festival in honour of Shakspere has been celebrated these last few years.

The town stands on the west or right bank of the Avon, and is approached from London by a long stone bridge of fourteen pointed arches, erected in the reign of Henry VII. at the sole charge of Sir Hugh Clopton, lord mayor of London, and widened of late years. There is another bridge just below, by which a railroad is carried across the river, and at the south end of the town is a wooden foot-bridge. The streets are irregularly laid out, but the principal ones are well-paved and remarkably clean. They are lighted in the winter with oil. The old houses are, many of them, commodious and well-built; some of the modern ones which are interspersed among them are capacious and handsome. The town has increased considerably during the last few years, and many houses have been built in the outskirts. The church is at the south-eastern corner of the

town, near the bank of the river. It is 'a large and handsome cross-church, the nave only separated for service. The transept, tower, and some parts of the nave are early English. The tower appears to have been strengthened by underbuilding the antient arches by others of perpendicular character. The upper part of it is decorated, with curious circular windows, having varied tracery. The south aisle is decorated, with some good windows; the west end of the nave, with the piers, arches, and clerestory, are perpendicular, as is the north porch. The chancel is late perpendicular, and a fine specimen of its date. On the north wall is Shakespeare's (Shakspere's) monument; on the south side are some stone stalls, and there are many of the wood stalls remaining. In the south aisle of the nave are the remains of some stone stalls which have had rich canopies. In some of the windows are portions of good stained glass. The present font is modern; the antient one, after being long a receptacle for rain water, is now carefully preserved in a gentleman's garden. It appears to have been perpendicular, of elegant design and good execution. The same gentleman also preserves part of the antient cross.' (Rickman, *Essay on Gothic Architecture*, Appendix.) The remains of Shakspere are buried in the chancel, on the north side, and are covered with a stone bearing this inscription:—

Good frend, for Jesus' sake forbeare
To digg the dust encloased heare;
Blese be ye man yt spares thes stones,
And curst be he yt moves my bones.

The monument against the wall is surmounted by a half-length effigy of Shakspere, executed with some taste and skill. It was originally coloured to represent life. Beneath the effigy is a poetical inscription consisting of a Latin distich and six lines of English verse; below the inscription is the record, 'OBIIT ANO. DOI. 1616, AETATIS 53, DIE 23 AP.' The church at Stratford was collegiate.

Besides the parish church there is a chapel-of-ease, anciently the chapel belonging to the brethren and sisters of the guild of the Holy Cross. At the dissolution of monastic institutions, the possessions of this fraternity passed to the crown, and were granted after some years to the corporation of Stratford for specific purposes. The chapel is of late perpendicular character, much like the chancel of the parish church. It was adorned within with fresco-paintings of singular character, which, after having been long covered with whitewash, were discovered during some repairs in 1804. They were too much injured however to allow of their being preserved. Adjoining the chapel is the hall of the guild, an antient building, which has undergone much alteration. The lower part is used for the business of the corporation, the upper part is occupied by the grammar-school. The residences of the schoolmaster and vicar, with the chapel and the hall of the guild, form three sides of a quadrangle. The town-hall, which is used for the larger meetings of the corporation and for other public purposes, is a modern building (A.D. 1768) of the Tuscan order. The principal room, 60 feet by 30, has some portraits; among them are one of Shakspere by Benjamin Wilson, and one of Garrick by Gainsborough. Outside of the building, on the west side, are the arms of the corporation; and on the north side, in a niche, is a statue of Shakspere. There are meeting-houses for Independents, Baptists, and Wesleyan Methodists. Part of the antient house, in which Shakspere is said to have been born, is standing in Henley Street on the north side of the town: a room is pointed out as the very chamber of his birth, and it may be really so: it is covered with the names of visitors. [SHAKSPERE.] 'New Place,' the residence of Shakspere in his latter years, was pulled down (A.D. 1759) by the Rev. Francis Gastrell, the owner, who had previously (A.D. 1756) cut down the famous mulberry-tree planted by the poet's own hand. The present theatre, a neat brick building, is appropriately placed within the precincts of Shakspere's garden.

The parish of Old Stratford, in which the town stands, has an area of 6860 acres; the population in 1831 was as follows: the borough of Stratford, 3488; the hamlet of Luddington, 127; outskirts of the borough and other parts of the parish, 1556: together, 5171. There were in the town 673 houses, inhabited by 683 families; 21 houses uninhabited, and 2 building. The only manufacture is that of Florentine silk buttons; the trade of the place, though not great, appears to be increasing. The navigation of the Avon commences here. The Stratford-upon-Avon canal runs from the north side of the town to the Worcester and Birmingham canal in the parish of King's Norton near Birmingham. It was made under several acts passed from A.D. 1793 to A.D. 1821. The Stratford and Moreton railway (constructed under Acts passed from A.D. 1821 to A.D. 1833) extends from near the termination of the canal to the town of Moreton-in-Marsh, Gloucestershire, 16 miles, with a branch (2¼ miles) to Shipston-on-Stour, in a detached portion of Worcestershire. The railroad consists of a single track, and horses are the moving-power: the railway crosses the Avon by a bridge. The coal brought by the canal from the South Staffordshire Coalfield [STAFFORDSHIRE] is sent forward to Moreton and Shipston by the railway; and stone and agricultural produce are brought back. The market at Stratford is now held on Friday, and is a considerable corn and cattle market. There are two yearly fairs, beside a statute-fair and several great cattle-markets.

Stratford is a municipal borough, but the borough limits do not include the whole town. The corporation was formed by a charter of Edward VI., A.D. 1553; and by the late Municipal Reform Act has 4 aldermen and 12 councillors. An enlargement of the boundary has been recommended. The borough is not to have a commission of the peace except on petition and grant. The borough courts had fallen into disuse previous to the passing of the act. The income of the corporation is considerable, consisting of the produce of the estate of the guild of the Holy Cross, and of the tithes formerly possessed by the college of priests belonging to the parish church. The corporation maintain an almshouse and the free grammar-school, and pay stipends to the vicar of Stratford and to a chaplain or vicar's assistant.

The living is a vicarage, of the clear yearly value of 239*l*., with a glebe-house: it is in the rural deanery of Kineton or Kington, in the archdeaconry and diocese of Worcester.

There were in the whole parish, in 1833, two infant-schools, with 240 children of both sexes; fourteen day-schools, with 664 children (viz. 432 boys and 204 girls, and 28 children of sex not stated); and three Sunday-schools, with 263 children; besides which, two of the day-schools, partly supported by voluntary contributions, with 130 boys and 60 girls, were also Sunday-schools. Two of the day-schools, with 130 boys and 70 girls, were national schools; another, with 12 boys, was the free grammar-school; and a fourth, with 28 children, was supported by voluntary contributions: the remainder, except the two which were also Sunday-schools, were private schools.

STRATFORD, FENNY. [BUCKINGHAMSHIRE.]

STRATFORD, STONY. [BUCKINGHAMSHIRE.]

STRATA. In Geology, both the separately deposited layers of rock, and the rocks formed of these similar layers, accumulated together, have received the name of strata. Dr. William Smith uses the term in the latter sense, and in general this is the meaning attached to it in those useful tabular expositions of the 'Series of Strata,' in various districts of the globe, which are now familiar to geologists. In special and local descriptions of rocks, the several beds are commonly enough called strata (*couches*, French). As a general scheme showing the rank frequently assigned to these and other terms, the following view may be useful, the most comprehensive term being to the left:—

Systems, Formations, Strata, Beds, Laminæ.

The terms series and group are very conveniently employed to collect under one head for purposes of reasoning, any of the laminæ, beds, strata, formations, or systems (or parts of one formation and parts of another), without any other limit than that imposed by the principle of grouping. For instance, the *Belemnitic Series* of strata includes the lias formation, lower, middle, and upper oolite formations, and the green-sand and chalk formations; it includes two systems of strata: by the *Trilobitic Series* of strata we may understand the whole of the Palaeozoic deposits, excepting perhaps the magnesian limestone and the oldest of the slaty rocks. [STRATIFICATION; GEOLOGY, &c.]

STRATICO, SIMONE, COUNT, born at Zara, in Dalmatia, in 1730, of a family originally from Candia, studied at Padua, where he took his doctor's degree, and was made professor of medicine in that University when only twenty-five years of age. In 1761 he accompanied to England the ambassador sent by the Venetian senate to congratulate George III. on his accession; and on his return to Padua he succeeded the Marquis Poleni in the

chair of mathematics and navigation. He wrote several works on hydraulics and hydrostatics, and upon naval architecture and navigation. In 1801 he was appointed by the government of the Italian republic to the chair of navigation in the University of Pavia, and under Napoleon's kingdom of Italy he was made inspector-general of roads, rivers, and canals, and senator of the kingdom and knight of the iron crown. After the Restoration the emperor of Austria gave him the cross of the order of St. Leopold. Count Stratico died at Milan, in 1824, at the age of ninety-four. His principal works are—1, 'Raccolta di Proposizioni d' Idrostatica ed Idraulica,' Padova, 1773; 2, 'Vocabolario di Marina,' 3 vols. 4to., Milan, 1813-14; a work which was wanted in the Italian language. Stratico collected the nautical expressions used by the Venetians, Pisans, and Genoese, in the time of their maritime greatness, and added the modern expressions adopted from the French and English; 3, 'Bibliografia di Marina,' 1823; 4, 'M. Vitruvii Pollionis Architectura cum Exercitationibus J. Poleni et Commentariis Variorum,' Udine, 1825. This is an excellent edition of Vitruvius, with important illustrations and comments by Poleni and Stratico, and was published after the latter's death. Stratico was one of the most distinguished men of science in Italy. His cabinet of models for shipbuilding, and his collection of books relative to the art of navigation, were bequeathed by him to the Lombardo-Venetian kingdom, and they have been placed in the library of the Institute of Milan.

(Maffei, *Letteratura Italiana:* Biographical Notice of Stratico, in the 'Antologia' of Florence, vol. xxi.)

STRATIFICATION. Mineral masses, separately deposited, and arranged into parallel layers under the influence of gravitation, compose a large portion of the known rocky crust of the earth, and are called stratified rocks. Other masses, in which no such successive deposition and tendency to be bounded by originally horizontal surfaces is traceable, are locally prevalent, and receive the name of unstratified rocks: they are generally supposed to be of igneous origin; the former are mostly known to be the fruit of sedimentary aggregation under water. To each class there are exceptions. Parts of certain limestone rocks, formed in water, as modern coral reefs, are really not at all or very slightly stratified: and certain melted rocks which have spread in successive sheets like lava over antient surfaces, or have been forced by great lateral pressure between really stratified rocks, often assume the stratiform aspect. Without now dwelling on these and several other exceptional cases, it is our purpose to present a general view of the present state of knowledge of the phenomena of stratification, as exhibited in rocks which show clearly the fact of their mineral particles having been separately subject, during the aggregation of the mass, to the influence of gravitation, while partially supported in media lighter than themselves, as water and air, and generally influenced by lateral movements, such as occur in a state of nature in those almost universal fluids.

1. Let us suppose a case of a shower of comminuted mineral matter falling through a limited section of air on the ground. It will be collected in a conical form, the slopes of the cone having reference to the velocity of descent of the sandy particles, the mutual support they yield one to another, and the form of the surface on which they fall. Omitting these sources of variation, the slopes of the conical heap will be generally within moderate limits of uniformity, and the inclination of these slopes constitutes what is called the *angle of rest*. A second shower of such sandy matters falling uniformly, will cover the cone with a parallel sheath, and thus *conical strata* may result from such operations repeated. (See diagram No. 1.) The nearest analogy to this

No. 1.

Vertical section of strata formed by conical superposition (theoretical).

type of stratification occurs in a volcanic cone; where however the showers of ashes falling not uniformly, but in different quantities in different directions, the result is a *streamy* or imperfectly concentric stratification, characteristic of the cause, and presenting on a cross-section an appearance as in the diagram No. 2.

2. If further we suppose a shower of ashes or sands to

No. 2.

Horizontal section of strata formed by falling of ashes round a vertical axis irregularly.

be much affected while falling by horizontal currents of air; in this case the supposed conical heaps No. 1 will be drifted, so as to show stratification inclined or dipping from the windy quarter. (See diagram No. 3.) Similar effects might follow the drifting of sand which had fallen into heaps.

No. 3.

Laminated deposits of sand by the effect of wind.

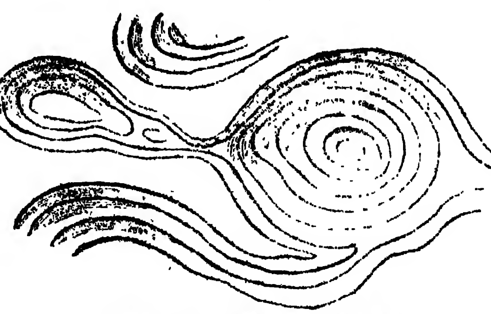
If the currents of air changed their direction at intervals, there would arise complication of the strata, *oblique stratifications*, such as are often seen in sandy rocks and sandhills, and these would be more or less distinct as the interval between the winds had been marked by vegetation, sediment, or any other cause of consolidation of the surfaces. (See No. 4.)

No. 4.

Oblique lamination in sand and gravel.

3. On surfaces of loose sand once deposited, under whatever of the influences stated, winds have the power of producing other effects; winds eddying among the inequalities of partially grass-grown sandhills, excavate in them circular, oval, or irregular pits, and make ridges and crests of fantastic forms. (Diag. No. 5.) Winds also wear away by

No. 5.



Excavation of cavities in sandhills by wind.

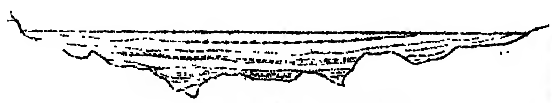
horizontal action the edges of these basins and crests, and make appearances of level stratification, as water which changes level wears its banks in parallel lines. Winds also by their peculiar action on fluid or loose masses, which move with a different velocity from the current of air, produce undulations on the surface of the sand lying across the current, and much resembling the 'ripple or current mark' (which is a secondary phenomenon from the same cause) on the beds of sand below agitated water.

The falling velocity in air of the different sorts of mineral particles which enter into the composition of rocks is not materially different, even if the masses be considerably unequal in size; but both in regard to falling in water and drifting by wind or water, the specific gravity and the magnitude of the masses require to be taken into account.

For our present purpose it is sufficient to observe that in a mixture of pebbles and sand, subject to drifting, there is an angle of ascent which limits the movement of the pebbles, and yet allows the sands to pass on. Hence, on the sea-coast, the almost stationary pebbly beach is margined on the landward side by parallel ridges of moving sandhills, and thus a separation is effected of the bases of conglomerates and the bases of sandstones.

If now, instead of comminuted materials falling through air on the land or drifted by wind over its surface, we imagine such materials falling on and sinking in lakes perfectly calm, or the sea always in motion, other effects will follow, and other forms of stratification will result. In a calm lake the sediment may be supposed to fall vertically downwards, and, except the bed of the lake be very irregular, to settle in layers or strata of considerable uniformity. The least lateral moment, by mixing the suspended matter through the water, would tend to widen the deposit, and to fill up the inequalities of the lake-bed, so that by many repetitions a very irregular subaqueous surface would be equalized and levelled. This effect is perhaps actually witnessed in the sediment called trass which lies in the valley of Brohl, near Andernach; this is apparently derived from volcanic dust stratified in the water which received the shower of ashes. (No. 6.) Besides showers of

No. 6.



Arrangement of ashes falling in a lake.

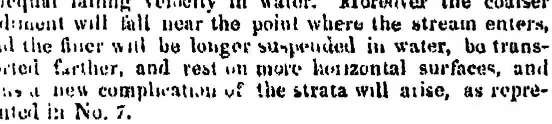
ashes, lakes and the sea receive comminuted mineral substances from shores wasted by tides and storms, and from rivers which transport detritus from the interior of the country. In a very calm lake the sediment from the influx of rivers subsides under the influence of gravitation downwards and communicated motion forwards, so that a kind of conical stratification in a delta continually advancing with a level top into the lake is the result. In this delta the arrangement of the strata is probably such as to exhibit successive layers dipping forward into the lake, but there may also be some more horizontal lines depending on the separation of the coarser and finer sediment, owing to their unequal falling velocity in water. Moreover the coarser sediment will fall near the point where the stream enters, and the finer will be longer suspended in water, be transported farther, and rest on more horizontal surfaces, and thus a new complication of the strata will arise, as represented in No. 7.

No. 7.

Deposition of coarse gravel and sand (g) and fine clay (c) in a lake by a river (r)

The earthy materials poured into the sea by rivers follow the same general laws of distribution, but are subject to the additional effects of tides and storms. The effects of these agencies are exhibited in great distinctness on coasts which confront violent winds and the full oceanic flow, and which are margined by pebbles and sands. The sands with ripple-marked surfaces gently inclined extend to some distance below low-water, the pebbles spread upwards in more steeply inclined banks thrown up and left by the breakers in heaps, long parallel ridges, and terraces. A contemporaneous surface of deposition in such cases may be as represented in No. 8, where clay or sand below low-water, and

No. 8.



Gravel beaches (g), sand beds (s), and fine clay (c), in the sea, under the influence of the tides.

pebbles between low and high water, appear in a continuous layer. Such a surface differs from that found under a calm lake by the concave slope of its pebbly laminæ toward the shore, while the lake deposit has convex slopes in the same part.

Such appearances, at least partially, may perhaps be recognised among the strata accompanying coal, and in other groups of rocks where the unequal size of the granular materials and antient exposure of these to littoral agitation supply the necessary conditions.

Near the shore various causes locally in operation are known to produce on the sea-bed that oblique and variously directed lamination which has been already noticed as an effect of wind (diagram No. 4), and may be seen as an ordinary occurrence in the sections of 'diluvium' and in the banks of rapid rivers which change irregularly their channel. (See the notice of this effect in the valley of the Arve, in Lyell's *Principles of Geology*.) Among the stratified rocks this appearance is common. It occurs in Sussex among wealden strata supposed to be of fluviatile origin; at Nottingham in new red-sandstone, which contains no internal evidence of the nature of the water in which it was arranged; in millstone grit of Yorkshire, and in the oolite of Weston near Malton, and Old Down near Bath, which are all deposits from the sea. It is perhaps impracticable to determine by mere inspection of the oblique lamination alluded to the exact order of phenomena which occasioned it. Tidal agitation, fluviatile violence, the force of temporary inundations, sea currents, each and all of these may have been concerned in the phenomena of this nature, which are so frequent in pebbly sandstones, and in general we may be justified in believing that such appearances may be safely ascribed in most cases to irregular violence of shallow water; while in regard to the more regular and extended parallel lamination of ordinary micaceous sandstones, and still more the fine uniform deposits of clay and argillaceous limestone, must be referred to the wider and gentler influence and longer suspension due to calmer, that is to say, generally deeper water, farther from shore.

The origin of the materials of stratified rocks is seldom obscure. Conglomerates full of pebbles rounded by attrition, sandstones with grains worn and rounded, shales and clays with broken and scattered mica, and disseminated fragments of other minerals, are so similar to ordinary accumulations by the diurnal agency of water, that no person can hesitate about the origin of such materials. Many of these are *recomposite rocks*; as the old red-sandstone conglomerates, which contain pieces of quartz from mineral veins, and masses of previously consolidated grauwacke. Others, as new red-sandstone, seem to be derived from wasting shores or the detritus of inundations; and certain schistose beds in the older strata of Devon, Cornwall, and Shropshire are positively aggregations of ashes, scattered by volcanic explosions on the antient ocean. It has been conjectured that the same explanation may apply to some other portions of the great series of Palæozoic slaty rocks, and in a few cases a direct reaggregration of the materials of trap rocks (Oban) or granite rocks (millstone grit of Derbyshire) appear. Well stratified limestones have probably been formed from precipitation of carbonate of lime, as now happens in lakes and in the sea; and the limited portions of the same rocks which show no such structure, are often certainly known to be, like modern reefs, the fruit of coralligenous polypiaria.

The changes to which the sedimentary deposits, which were the origin of stratified rocks, have been subject since their aggregation, are so considerable, as to gain for them, in extreme cases, the distinctive title of *Metamorphic Rocks*.

Consolidation of mass is the first of these changes to which we may here allude. It appears to be a phenomenon principally due to *pressure*: as in the buried peat of Dartmoor, and the buried clays of Holderness, the originally light and uncondensed matters have been compressed to some considerable firmness, solidity, and weight; so in respect of antient clays, mere pressure appears to be a sufficient cause for their condensed, often shaly consistence. But more than this must be appealed to for the *induration* of slate, coal, limestone, and sandstone. The *particles* of these rocks cohere with force, by a process of internal molecular arrangement; and it appears to be a fair inference from numerous facts, that among the most influential of the exciting causes of this molecular action is the internal heat of the globe—locally manifested in the induration of stratified masses in the vicinity of trap dykes and other igneous rock masses, and generally exhibited in the hardness, symmetrical structure, and crystalloid aspect of the lower and more antient strata, which may be supposed to have been more subject, and for a longer time than the others, to the influence of subterranean heat.

Very unequivocal signs of this action of heat appear in the vicinity of the granite rocks of Cumberland, Devon,

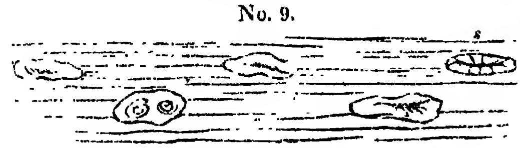
Cornwall, Wicklow, &c., and perhaps they are seldom absent from such situations. One of the most ordinary of such effects is the development, in the mass of the stratified rocks, of peculiar crystals, as felspar near the granite of Wastdale Head, in virtue of which slates become porphyry; of hornblende and chiastolite in those of Skiddaw, just as garnets are developed in argillaceous beds near the trap rocks of Teesdale and Anglesey. [Rocks.]

There is some danger of carrying too far the application of this doctrine. The metamorphism of rocks is a real and very extensive phenomenon, but we must have always a reason for referring to this class any peculiar appearances of stratified rocks which differ from the ordinary appearances of common aqueous sediments. We must not ascribe to re-arrangement of molecules what is not consistent with such an effect, nor without examination call textures of rocks imperfect crystallization and re-arrangement of molecules which perhaps may be only due to disintegration and re-aggregation of masses.

A case of this kind is very important; the primary strata of gneiss and mica-schist are often, without examination, but merely by applying as a universal consequence what really depends on very partial inquiry, declared to be crystallized, or crystalline, or crystalloid rocks; when, in fact, in many cases they are really, as MacCulloch knew, stratified aggregations of the disintegrated parts of crystallized rocks, and in others show evidence of the same origin, disguised by subsequently applied heat. [Geology—*Primary Periods*.]

Some cases of re-arrangement of particles depend on molecular action, not excited by heat, but determined to particular centres by the previous existence there of solidified bodies. Oolite is an example of common occurrence among limestones of the secondary class, and few things are more interesting to examine than a polished slab of the oolite of the mountain limestone of Bristol and Lancashire, or the pisolite of Wilts. In the centre of the spherical grains of the former, and in or near the axis of the less regular nodules of the latter, are grains of sand, bits of shells, or small foraminifera, and round these parallel coats of carbonate of lime are neatly and concentrically arranged. An extremely large and irregular pisolitic nodule gives us the link between these concretionary arrangements and the 'nodules' or 'balls' of limestone and ironstone which enclose pieces of plants, leaflets of ferns, shells, bones, or fish-scales, and lie in parallel layers in the coal-shales, lias clays, &c. These balls are evidently formed by accretion round the organic objects which they enclose, and the process is the more curious, because the matter of the ball is usually more calcareous or more ferruginous than the surrounding matrix, and seems to have been collected from out of it by some peculiar elective attraction depending on the nature of the organic body. (See Diagram No. 9.)

No. 9.



Re-arrangement of deposited matter in nodules, round organic or inorganic masses; *s*, one of these cracked as in Septaria.

In addition to this process it has frequently happened that the 'ball' has been cracked internally across by subsequent contraction during *consolidation*, and the cracks are filled by carbonate of lime, iron pyrites, silica, &c., introduced through the apparently solid texture of the external parts according to the peculiar circumstances of the operation. Thus by a peculiar species of electrical transfer, analogous to what is supposed in the case of mineral veins, the internal cavities become filled, and the result is the septarium, for whose formation internal heat was once deemed necessary by the advocates of the Huttonian hypothesis. (Playfair's *Illustrations*, p. 30.) Derived from sources so various, and aggregated under aqueous agencies so diversified in respect of power and direction, it is not surprising that the stratified rocks present themselves in a variety of appearances. It is clear that in the same bed of the antient sea, or on the same basin of the actual sea, contemporaneous surfaces of deposition might extend over calcareous, argillaceous, arenaceous, and pebbly deposits: that in different basins contemporaneous deposits might be extremely unlike; and that metamorphism, more or less important, must be allowed to have often further increased such original diversity. Yet, notwithstanding these limitations, it appears to be a fact sufficiently established that there are general characters of mineral composition and structural aggregation which are associated with the strata of each great period of the earth's history, so as more or less completely to distinguish one period from another. [Geology.]

STRATON, the son of Arcesilaus, and a native of Lampsacus, a Peripatetic, who about B.C. 286 undertook the charge of the Peripatetic school after Theophrastus. He was the master of Ptolemy Philadelphus, and was well paid for his services.

Respecting his doctrine only scattered hints can be gathered, as all his works have perished. He differed from his master Aristotle on certain points. He maintained that there was a principle of motion destitute of intelligence inherent in all matter; which principle causes all composition and decomposition of bodies; that the world, in consequence, was not formed by an extramundane deity, nor by any intramundane animating pervading intelligence: but it was formed by the innate force of matter, which momently creates and dissolves. He was called Physicus (φυσικός), from his making physical matters his chief study. A list of his works is given by Diogenes Laertius (*Straton*), and a copy of the philosopher's testament.

Eight persons of the name of Straton are enumerated by Diogenes.

(Diog. Laert., 'Straton;' Cicero, *De Natura Deorum*, i. 13; Brucker, *Instit. Hist. Phil.*)

STRATTON. [Cornwall.]

STRAUBING is a considerable town in the province of Lower Bavaria (previously called the circle of the Lower Danube), in the kingdom of Bavaria, in 48° 53′ N. lat. and 11° 35′ E. long., in a pleasant country, on an eminence on the right bank of the Danube. The town is divided into the Upper and Lower town, and is surrounded with walls, in which there are four principal gates; but the walls are now for the most part broken, and the moat converted into gardens. It is tolerably well built. The population is about 7000. The Danube here divides into two arms, one of which flows close by the town, half a league below which they again unite. There is a stone bridge 325 feet in length over the Danube, from which the unfortunate Agnes Bernanernon, wife of duke Albert, was thrown on the 12th of October, 1435, by order of her father, a citizen of Augsburg, without whose knowledge the Duke had married her. She was celebrated for her extraordinary beauty. Her husband erected a handsome monument to her in St. Peter's church, which still remains. The principal public buildings are the seven churches, the palace, the government-house, the gymnasium, and the town-house. There are four hospitals, a seminary for schoolmasters, a convent of Ursuline nuns, in which there is an establishment for female education, and numerous charitable institutions. The handsomest part of the town is the great square, in which are the church of the Holy Trinity, the palace, the town-house, the government-house, and the church of St. James and St. Veit. This town has, properly speaking, no manufactures, but it has a good trade on the Danube, and great corn and cattle markets. The surrounding country is remarkably fertile. The town has frequently suffered by extensive fires.

STRAW-PLAT MANUFACTURE AND TRADE. The domestic character of this branch of industry, which renders it peculiarly important as a means of affording employment to women and children, especially in agricultural districts, may probably account for the circumstance that very little is known of its history. An interesting account of this manufacture is given in M'Culloch's 'Dictionary of Commerce,' in the article 'Hats,' and some information on the subject may be gleaned from the published 'Transactions' of the Society for the Encouragement of Arts, Manufactures, and Commerce. From these and some minor sources of information, the following details are derived.

The article first alluded to (which is stated to be written by Mr. Robert Slater, of Fore Street, London) observes, that it is not known when the manufacture of hats or bonnets of platted straw first became important in Italy, where it has long formed one of the leading pursuits of the

agricultural population, but that it appears from Coryat's 'Crudities,' published in 1611, that 'delicate strawen hats' were worn at that time by both men and women in many places in Piedmont. Coryat states that many of these hats had at least a hundred seams, from which it is evident that very fine plat was made at that time. The same article states that the straw-plat manufacture does not appear to have been followed in England for more than sixty or seventy years, 'as it is within the remembrance of some of the old inhabitants of the straw districts, now alive, that the wives and daughters of the farmers used to plait straw for making their own bonnets, before straw-plaiting became established as a manufacture.' This was published in 1834. Gipsy straw-hats were worn by ladies in this country about 1745-6, according to the 'Pictorial History of England' (vol. iv., p. 806). When Arthur Young visited Dunstable, in 1768, the straw-plat manufacture appears to have been established, though not very extensively. He says (*Six Months' Tour*, vol. i., p. 16), 'At that place is a manufacture of basket-work, which they have carried to a great perfection of neatness, and make of hats, boxes, baskets, &c. a large quantity annually; but not a great number of hands are employed by it.' In the 'Commercial Gazetteer' appended to Macpherson's 'Annals of Commerce,' published in 1805, Dunstable is described as 'a town in the neighbourhood of which the women and children are employed in making hats, baskets, and many fancy articles, of straw, which in their hands assumes a vast variety of figures and colours, and produces considerable emolument, especially since the straw hats have been in general request among the ladies.'

The large size of the wheat-straw used in this country for platting prevented the home manufacture from entering into competition with that of Italy in articles of fine quality; the straw grown for the purpose in Tuscany being much smaller, as well as superior in colour. This difficulty was in some degree overcome by the expedient adopted in England towards the end of the last century, of splitting the straw, and using the narrow *splints*, or slips of straw, in lieu of whole straws. The operation of splitting is performed by small cutting instruments called *machines*, which have a number of sharp edges so fixed as to divide the straw, by a motion in the direction of its length, into four, five, six, or more equal parts. Before machines were invented, straws were occasionally split with knives by hand; a process which was both tedious and unsatisfactory, since it gave no security for the uniform width of the splints, upon which the beauty of the plat greatly depends. It has been stated that the ingenuity of the person who contrived the machine used for this purpose was rewarded by realising a fortune of 30,000*l.*; but a communication from a correspondent at Watford gives a very different account of the matter. Our informant states that his father, Thomas Simmons (now deceased), was residing when a boy, about the year 1785, at Chalfont St. Peter's, Buckinghamshire, and that when amusing himself one evening by cutting pieces of wood, he made an article upon which he put a straw, and found that it divided it into several pieces. A female who was present asked him to give it to her, observing that if he could not make money of it, she could. She had the instrument, and gave the boy a shilling. He was subsequently apprenticed to a blacksmith; and, on visiting his friends, he found them engaged in splitting straws with a penknife. Perceiving that the operation might be much better performed by an apparatus similar to that which he had made some time before, he then made some machines of iron on the same principle. So far from realising a fortune by the invention, his son states that he only realised one shilling. The inconvenience of the process as performed by hand may possibly have led more than one individual to devise similar means for overcoming the difficulty. Be this as it may, the introduction of split straw gave a great impulse to the plat manufacture. Mr. Corston, in a letter addressed to the Society of Arts in 1810, observes that 'by the mere invention of the splitting of a straw a source of employment has been discovered, which has increased the returns in that branch not less than from 300,000*l.* to 400,000*l.* annually.'

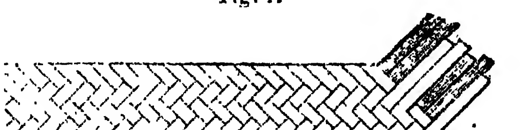
Greatly as the British straw-plat manufacture had been encouraged by the use of split straw, by improvements in bleaching, and by increased care in the selection of straws of uniform size and colour, it was found, when the re-establishment of peace allowed the free importation of Italian straw hats, that the home manufacture was unable to compete with the foreign, notwithstanding the heavy protecting duty levied upon hats or bonnets of straw imported from other countries. The Society of Arts has therefore, for a long series of years, offered encouragement to attempts for the improvement of the British straw manufacture, which has called forth many interesting communications, and has led to great improvement. As early as 1805, the Society presented a gold medal to Mr. William Corston, of Ludgate-hill, for a substitute, of his invention, for Leghorn plat. His plat was formed of rye-straw, and was so good that some specimens had been examined by London tradesmen, who confessed their inability to discover the difference between them and the real Italian Leghorn. Mr. Corston states that 781,605 straw hats had been imported from 1794 to 1803; and that in the last four years of that period 5281 lbs. of straw-plat, which was equal to 26,405 hats, had also been brought to this country. By the introduction of his new plat, it was considered that much poor land might be brought into profitable cultivation, and that employment might be provided for many females and children. In a subsequent communication, dated May, 1810, Mr. Corston states that the country was beginning to reap the benefit of his proposals. (*Trans. of the Soc. of Arts*, vols. xxiii. and xxviii.) More recently rye-straw has been tried for the same purpose by Messrs. J. and A. Muir, of Greenock, who attempted to establish the straw-plat manufacture in the Orkneys. These gentlemen communicated the results of their experiments to the forty-fourth and forty-fifth volumes of the 'Transactions' of the Society of Arts. The manufacture is still followed in the Orkneys.

In the fortieth volume of the Society's 'Transactions,' which was published in 1823, the defects of British straw plat were particularly noticed. In plat made of split straw, unless two splints are laid together, with their inside surfaces towards each other, as in the plat called 'patent Dunstable,' it necessarily happens that the face of the plat exhibits alternately the outer and inner surfaces of the straw, which differ from each other in colour and gloss. Articles made of split straw are also inferior to those of whole straw of equal fineness, in pliability and durability. Another circumstance which greatly increases the beauty of Leghorn plat is the mode of joining it, so as to form, by the combination of several narrow strips, an extended sheet of platted work. British plat is usually joined by making the several rows of plat overwrap each other a little, and then stitching through the two overwrapping pieces with a needle and thread. The surface of a hat or bonnet formed in this manner consists of a series of ridges; and part of each row of plat is concealed by that next above it, so that an unnecessarily large quantity of plat is required to form a given extent of surface. Thus to form a band one inch wide, with a plat a quarter of an inch wide, it will be necessary to use *five* pieces of plat; at least a fourth part of the width of each being absorbed by the overwrapping joint. Leghorn plat is formed in such a manner that it may be joined without this loss; the edge of one row of plat being, as it were, knitted into the edge of the other, in such a way that the pattern may appear uninterrupted, and the line of junction may be almost invisible. In addition to these differences of quality, it is stated that the cheapness of labour on the Continent gave a great advantage to foreign competitors; so much so, indeed, that the best Hertfordshire straw might be, and actually was, sent to Switzerland, platted there, and thence returned to England, paying the import duty of 17*s.* per lb., and yet sold 25 per cent. cheaper than that platted in this country. The Society were therefore very desirous of promoting such improvements in British straw-plat as might place the manufacture in a more favourable position. With this view they awarded, in 1822, a silver medal and twenty guineas to Miss Sophia Woodhouse (afterwards Mrs. Wells), of Connecticut, in the United States, for a new material for straw plat. This material is a kind of grass (poa pratensis) which grows spontaneously in that part of the United States, and is there called 'ticklemoth.' The plat she formed of it is stated to be superior to Leghorn in fineness and colour. Miss Woodhouse sent seeds to the Society, from which the grass was raised in this country; and she also communicated an account of the process of manufacture. (*Trans. of the Soc. of Arts*, vol. xl.) In the following year, Mr. Cobbett communicated to the Society his experiments on native British grasses, of which several appeared likely

to answer for platting; and some rewards have been since bestowed for experiments of like character. Before noticing these, allusion must be made to another, and a very important paper, in the fortieth volume of their 'Transactions.'

The paper alluded to is a communication from Mr. John Parry, who received, in 1822, the large silver medal of the Society for the manufacture of Leghorn plat from straw imported from Italy. The import duty charged upon straw-plat was then, as it still is, considerably less than that upon straw hats or bonnets, and the duty on unmanufactured straw still less in proportion. The home manufacture of Italian straw had been tried, but without success, by Mr. Bigg; and it was afterwards attempted by Mr. Parry, who, at the date of his communication, had more than seventy women and children employed in it. The ears are, it is stated, cut off with a knife, and the straws are then carefully sorted to obtain uniformity in length, thickness, and colour. The plat of which the formation is described, and of which an engraving is given to illustrate the description, consists of thirteen straws. These are to be tied together at one end, and then divided into two portions; six straws being turned towards the left side, and seven to the right, so that the two portions of straw may form a right angle. The seventh or outermost straw on the right-hand side is then to be turned down by the finger and thumb of the right hand, and brought under two straws, over two, and under two. This being done, there will be seven straws on the left and six on the right side of the angle; and the next operation is to turn down the outermost of the seven with the left-hand finger and thumb, and to pass it under two straws, over two, and under two. The right side will again have seven, and the left side six straws; and the platting must be continued in the same manner, alternately doubling and platting the outermost seventh straw from side to side, until it becomes too short to cross over so as to double on the other side of the angle. The platter is then to take another straw, and to put it under the short end at the point of the angle (the middle of the plat), and, by another straw coming under and over the joined one from both sides of the angle in the operation of platting, it will become fastened; the short end being then left out underneath the plat, and the newly fastened straw taking its place on that side of the angle to which the short one was directed. The plat thus formed is represented in the cut *Fig.* 1, copied from the engraving which accompanies Mr. Parry's communication. It is about double the real size. The plat is formed in pieces

Fig. 1.



of great length, which are adjusted in spiral coils, with their adjacent edges knitted together, so as to form the large circular pieces of plat which, under the name of hats, or *flats*, are so extensively exported from the north of Italy. The mode of effecting the junction is described in the same volume, and may be explained by the help of the annexed cuts. *Fig.* 2 represents, about four times the real size, the two adjacent edges when knitted together; the dotted lines indicating the edges of each piece of plat, and showing how far the angular folds, or *eyes*, of one piece are inserted into those of the adjoining piece. The thread by which the two rows of plat are held together is here straight, and is entirely concealed in the plat. The joint is, indeed, only to be detected on either side by the slightly increased thickness of the plat where the angles are inserted into each other, and the thickness of the thread itself. The mode of junction may perhaps be better understood from *Fig.* 3, which represents the pieces of plat drawn a little asunder, and shows the course of the thread, which is indicated by dotted lines where it is covered by the straw. The operation is performed by pushing a needle through the folds in the required order, and, after passing it through as many as can be conveniently done at once, drawing it through in the manner of a bodkin, leaving its place to be taken by the

Fig. 2.

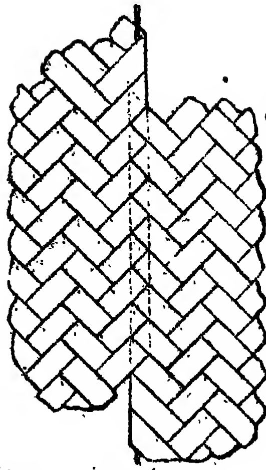


Fig. 3.

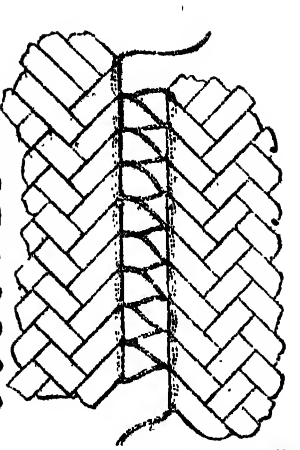

thread. It is observed that if the edges of the plat are not thrust sufficiently close, the needle will miss some of the folds, and the junction, though not visibly imperfect, is really so. It is further stated that sometimes, for the sake of expedition, only every other fold is threaded. This is a very injudicious practice, because it requires a coarser thread to make the junction secure, and therefore, by rendering the line of junction more prominent, impairs the beauty of the work. In arranging the plat in a spiral coil, as in making a hat, it is necessary, in a few places, to force two loops of the smaller circle into one of the larger circle adjoining it, to allow for their different diameters.

The information thus circulated respecting the mode of manufacturing Italian plat, has been of great importance to the British manufacture. In the year after it was published the Society of Arts rewarded sixteen individuals for the production of bonnets formed of grasses indigenous to Britain, platted and joined according to the Italian methods. Several of the specimens produced were even finer than real Leghorn; but it should be remembered that such extreme fineness can only be attained by a sacrifice of strength, and also that it increases the work. Most of them were imperfect in colour and regularity of size; but these defects are not incapable of remedy. The Society reported, that 'Upon the whole it appears to be satisfactorily proved that the stems of the crested dog's-tail grass are a material for plat finer than the average quality of Leghorn; and that the deficiencies in texture and colour of most of the bonnets produced before the Society are only such as practice and experience will shortly remove.' (*Transactions*, vol. xlii., p. 79.)

Various statements have been made respecting the material commonly used for plat in Tuscany. According to a communication made by Mr. W. Salisbury to the Society of Arts (*Transactions*, vol. xliii., p. 21), the straw used is that of *triticum turgidum*, a variety of bearded wheat, which seems to differ in no respect from the spring wheat grown in the vale of Evesham and in other parts of England. It is grown in Tuscany solely for the straw, and not for the grain; and the upper joint of the straw is that chiefly used for platting. Dr. Ure states (*Dict. of Arts, &c.*, p. 1190) that the straw is pulled while the ear is in a soft milky state; the corn having been sown very close, and consequently produced in a thin, short, and dwindled condition. It is then dried by spreading it thinly upon the ground in fine hot weather, and afterwards tied up in bundles and stacked, for the purpose of enabling the heat of the mow to drive off any remaining moisture. 'It is important,' he further says, 'to keep the ends of the straw air-tight, in order to retain the pith, and prevent the gummy particles from passing off by evaporation.' After remaining in the mow for about a month, it is spread out in a meadow, and exposed to the action of dew, sun, and air, in order to bleach it. The straw is frequently turned during this operation; and after it is completed, the lower joint of the straw is pulled off, leaving the upper joint, with the ear attached to it, for use. This part is then subjected to the action of steam, and to fumigation with sulphur, in order to complete the bleaching, after which it is ready for use. It is tied up in bundles, and imported to England in this state.

Bleaching with sulphur is commonly practised in this country, and Dr. Ure states that a solution of chloride of lime may be used for the purpose. The apparatus he describes for the former process consists of a cask open at both ends, with its seams papered. It is to be set upright on the ground, having a hoop nailed to it inside, about six inches beneath the top, to support another hoop with a net stretched across it, upon which the straw is to be laid loosely. The cask is then covered with a tight overlapping lid, stuffed with lists of cloth. A brazier of burning charcoal is inserted beneath the cask, and upon this is placed an iron dish containing pieces of brimstone. The brimstone soon takes fire, and the sulphurous acid gas evolved during its combustion fills the cask, and bleaches the straw in three or four hours. Care must be taken to prevent the too rapid combustion of the sulphur, which might cause black burned spots on the straw. After bleaching, the straw is to be aired and softened by spreading it upon grass for a night, and it is then ready for splitting.

Straw may be dyed, for ornamental purposes, of many different colours. Dr. Ure states that blue is given by a boiling-hot solution of indigo in sulphuric acid; yellow, by decoction of turmeric; red, by boiling hanks of coarse scarlet wool in a bath of weak alum-water containing the straw; or directly, by cochineal, salt of tin, and tartar. Brazil wood and orchil are also employed for dyeing straw.

The *splints*, or pieces of split straw, being curved in a way which would impede the operation of platting, require to be flattened between rollers. These, as well as the whole straws used in other kinds of plat, are moistened with water to render them easy to work. It need hardly be observed that cleanliness is indispensable to the beauty of the plat. Hence the Italian platters find the spring to be the most favourable season for the work, as the plat is not then exposed to the smoky atmosphere of the huts as in winter, nor to the dust and perspiration of summer. The Italian plat is dressed and polished by passing it forcibly between the hand and a sharp piece of wood. It is needless to enumerate the varieties of straw-plat, of which there are many, differing in the number and mode of platting the straws, in the circumstance of the straws being whole or split, &c.

In the kind of straw-platting above described, the plat is formed into a narrow strip or riband, which must be formed into a spiral coil, or united edge to edge, to form a hat or bonnet. In 1834, Mr. T. B. Smith, of St. Alban's, received a prize from the Society of Arts for applying Brazilian plat to the manufacture of hats and bonnets of split straw. This kind of plat is not formed in strips, but is at once platted or woven into the required form and size. The process is fully explained, and illustrated with cuts, in the fiftieth volume of the Society's 'Transactions.' One advantage claimed for the method is that either the glossy or the dull surface of the split straw may be placed entirely on one side of the plat.

The British straw-plat district comprises Bedfordshire, Hertfordshire, and Buckinghamshire; those counties being, according to M'Culloch's 'Dictionary,' the most favourable for the production of the wheat-straw commonly used for English plat. The manufacture is also followed, according to the same authority, in a few places in Essex and Suffolk; but very little in other counties. The principal markets are Luton, Dunstable, and St. Alban's. In Italy the manufacture is chiefly followed in the neighbourhood of Florence, Pisa, Siena, and the Val d'Arno, in the duchy of Tuscany; and it is also established in Venice and other places. There, as in England, the manufacture is purely domestic. The chief market is Florence; and the demand is principally from England, France, Germany, and America. Of late years the demand has fallen off so greatly, that many of the Italians have abandoned the manufacture.

The following tables, compiled from official returns, will show how greatly the imports of straw hats have diminished of late years, especially from Italy; and will also indicate, by the increased imports of straw-plat and straw for platting, the gratifying progress of that department of the British manufacture in which foreign materials are used with home labour.

I. Table showing the number of *straw hats* imported, exported, and entered for home consumption, and the net revenue derived therefrom, in each period of five years, from 1820 to 1839:—

Years.	Imported. Number.	Exported. Number.	Home Consumption. Number	Net Revenue £.
1820-4	676,479	42,905	626,236	180,5[illegible]
1825-9	1,356,767	70,455	1,217,221	343,[illegible]
1830-4	458,437	174,432	356,258	101,[illegible]
1835-9	83,600	73,824	20,299	6,6[illegible]
	2,575,283	361,616	2,220,014	£631,4[illegible]

During the period embraced by this table the import duty was as follows:—*3l. 8s.* per dozen upon hats not exceeding twenty-two inches in diameter, down to August 16, 1837, and not exceeding twenty-four inches in diameter after that date; and *6l 16s.* per dozen for hats of larger dimensions. We are not acquainted with any published data for showing, for the whole of this period, the proportionate amount of imports from different countries; but from 1827 to 1829 about 83¾ per cent. of the total number of straw hats imported were from Italy, about 15¼ per cent. from France, and rather less than 1 per cent. from Holland and Belgium. In the five years from 1830 to 1834, the principal imports were—from Italy, 89½ per cent. of the whole; from France, about 8½ per cent.; and from the United States, about 1¼ per cent. From 1835 to 1839 the proportions were about as follow:—Italy, 38½ per cent.; France, 26⅗ per cent.; Philippine Islands, 14⅗ per cent; United States, 17⅞ per cent.; East India Company's territories, 6⅗ per cent.; British North America, 3 per cent.; and Russia, 1⅗ per cent. The remaining fraction in each case consists of very small quantities imported from various places.

II. Table showing the quantities of *straw-platting* imported, exported, and entered for home consumption, and the net revenue derived therefrom, in each period of five years, from 1820 to 1839:—

Years.	Imported. lbs.	Exported. lbs.	Home Consumption. lbs.	Net Revenue £
1820-4	9,051	..	8,497	7,224
1825-9	38,585	2,629	31,153	26,176
1830-4	116,241	10,096	89,794	74,813
1835-9	185,789	52,685	141,956	119,085
	349,666	65,410	271,400	£227,398

The import duty on straw-platting, during the whole of the above period, was at the rate of *17s.* per lb.

III. Table showing the quantities of *straw and grass for platting* imported, exported, and entered for home consumption, the rate of duty, and the net revenue derived therefrom, from 1820 to 1839:—

Years.	Imported. £	Exported. £	Home Consumption. £	Rate of Duty.	Net Revenue £
1820-4	..*	..	..	20 per cent. ad valorem.	..
1825-9	12,100	..	12,100	10 per cent. ad valorem.	3,081

	Cwts.	Cwts.	Cwts.		
1833-4	4,479	40	4,784	*1d.* per cwt.	9
1835-9	17,172	252	16,928	Do.	72

STRAWBERRY, the English name of the fruit and plant of the *Fragaria*, a genus of plants belonging to the natural order Rosaceæ. The fruit of the Fragaria is one of the most delicious of our summer fruits. The name Fragaria is derived from the Latin *Fragum:* and the English name from the practice in this country of cultivating the plant with straw surrounding it.

The genus Fragaria is known in its family by possessing a calyx with a concave tube, the limb of which is 10-parted, and the outer 5 segments accessory; 5 petals; stamens and carpels indefinite, the latter placed upon a fleshy and succulent receptacle, forming the juicy and succulent part of the fruit.

The species are perennial plants, throwing out runners: the leaves are trifoliate, each leaflet being coarsely toothed: the receptacle on which is seated the carpels, and which is called the fruit, is round, and assumes a variety of colours from a scarcely perceptible pink to a dark red

* This is for 1834 only; the tables issued by the Board of Trade (part iii., 1820-33) state that in 1833 the repayments exceeded the gross receipts

Several species of this genus have been described. Linnæus gave only two; but Wildenow admitted eight; and Geo. Don, in 'Miller's Dictionary,' enumerates fourteen. Duchesne, who is followed by many French botanists, makes only two species, and makes the species of other writers varieties of these. All of them are natives of temperate or cold climates; and are found in Europe, America, and the mountains of Asia.

As with regard to plants so extensively cultivated as the strawberry, it is frequently difficult to distinguish between the varieties and species, we shall follow Don, and enumerate those species which afford the varieties of cultivated strawberries.

Wood or alpine strawberry (*Fragaria vesca*) has plicate leaves, pilose beneath; the sepals reflexed, and the hairs on the peduncle pressed down. It is found wild in woods and on hill-sides throughout Europe, and is abundant in Great Britain. Duchesne describes eight varieties of this species, mostly characterised by the different form of the fruit or fleshy receptacle. Many of these produce the cultivated varieties which are known in gardens. The *F. v. semperflorens* produces the red, the white, the American, and Danish alpine strawberries, all of which are of a fine flavour, and greatly valued. *F. v. minor* produces the red wood-strawberry, or *frasier d'Angleterre*, and the white wood strawberry, both very fine kinds. To the *F. v. eflagellis* belongs the red and white alpine bush-strawberry, but these do not produce so good fruit as the last.

Hill strawberry (*Fragaria collina*) has the sepals erect after flowering, and the hairs on the peduncles and calyx erect. This species is a native of Switzerland and Germany, and is characterised by its producing green fruit. The varieties of strawberries which are called green are the produce of this species. In flavour and size they are only a second rate strawberry.

The Majaufe of the French (*Fragaria Majaufea*) has long stamens, with the calyx pressed down after flowering. This species is a native of France, and produces a fruit which is known in that country under the name of *Majaufe*.

Hautbois strawberry (*Fragaria elatior*) has the sepals reflexed on the peduncle, the hairs of the peduncles and petioles extending horizontally. It is a native of North America, and is occasionally found in groves in the south of England. The shape, size, and colour of the fruit of the hautbois are subject to great varieties, according to its mode of cultivation. It is the parent of a great number of sorts known in gardens, most of which, when properly managed, produce fruits of a first-rate kind. The most common of these are the black, brown, and common hautbois; the globe, the large flat hautbois, the long-fruited muscatella, and Sir Joseph Banks, belong to this species.

Virginian strawberry (*Fragaria virginiana*) has the calyx expanded after flowering; the hairs of the peduncle pressed down, and those of the petiole upright. It is a native of Virginia, and to this species belong the great list of sorts cultivated in gardens and known by the name of scarlet and black strawberries. The various kinds of scarlet, globe, cone, and some pine strawberries are produced from this species.

Large-flowered strawberry (*Fragaria grandiflora*) has leaflets glaucous, coriaceous, crenated, glabrous above, and pilose beneath; reflexed sepals, and hairs on the peduncles and petioles spreading. It is a native of Surinam, and has furnished our gardens with the sorts called pine strawberries. The various sorts named Bath, pine, Carolina, Dutch, and others, belong to this species.

Chili strawberry (*Fragaria Chilensis*) has leaves obovate obtuse, with silky villi beneath; calyx erect, hairs on peduncles and petioles spreading. It is a native of South America, both in Chili and Peru, and is the parent of a number of mostly inferior strawberries.

The other species of Fragaria do not bear strawberries that are worthy of cultivation.

Strawberries, when ripe, may be eaten in almost any quantity without injury. They are frequently eaten mixed with sugar and cream or wine. When ripe and well grown they hardly require such additions; but when their sugar is deficient, this ingredient may be safely added; and the addition of wine under these circumstances should be preferred to cream, as the latter is very liable to disagree with disordered stomachs.

Strawberries may be propagated either by means of their suckers or runners, or by sowing seed. The young plants will generally bear the year after they have been planted or sown. In order to obtain the fruit in perfection, they should be planted where they have access to abundance of light and air. Plants grown from runners are best for new beds, and should be planted out in March, in beds with three or four rows, leaving an alley between each bed. The alleys should be wide, the beds kept clear from weeds, and the runners cut at least three times in the season. In the autumn the rows should be dug between, and in the spring some straw or dung should be laid between the rows. If the latter produces too luxuriant a growth of the plants, it should not be employed. The *pine strawberries* require a light loam. The rows of the beds should be two feet apart, the plants eighteen inches asunder, and the alleys three feet wide between each bed. The *scarlet strawberries* may be treated in the same manner. The duration of these and the preceding strawberries is about three years. The *hautbois* require a light soil and the same general treatment; and as they are diœcious, care should be taken that there are male plants in the bed in the proportion of about one to ten. The *wood-strawberry* is best produced from seed, which should be sown as soon as it is obtained from the fruit, and should be planted in beds in March, in the same way as the others. The *alpine strawberry* is best grown from seeds, which should not be sown till the spring, and may be planted in July or August, in rows at the back of hedges or walls, in a rich or moist soil. The duration of these and the last seldom exceeds two years.

As a choice selection of sorts that can be procured for the garden, Mr. Lindley recommends the following:—Austrian Scarlet, Black Roseberry, Grove-end Scarlet, Old Scarlet, Roseberry, Downton, Sweet Cone—all varieties of *Fragaria virginiana*; Black Prince, Elton's Seedling, Keen's Seedling, Old Pine—varieties of *F. grandiflora*. Large Flat Hautbois, Prolific Hautbois—varieties of *F. elatior*; Red Alpine, White Alpine—varieties of *F. vesca*; Wilmot's Superb, Old Scarlet—varieties of *F. Chilensis*.

For further information see Lindley's *Guide to the Orchard and Kitchen-Garden*; Don's 'Miller,' vol. ii.; *Hort. Transactions*, vol. ii

STREATHAM. [SURREY.]

STREETS, PAVEMENT OF. [ROAD.]

STRELITZ, the capital of the grand-duchy of Mecklenburg-Strelitz, is situated in 53° 25′ N. lat. and 13° E. long. It consists of two parts, Old Strelitz and New Strelitz, which are not quite contiguous, but about a mile distant from each other, and though considered as one town, each has its own magistrates. Old Strelitz, which was formerly the residence of the duke, has 3500 inhabitants, among whom there are 450 Jews, who have a synagogue, a rabbi, and their own judges. The inhabitants manufacture leather, tobacco and tobacco-pipes, and are partly employed in agriculture and gardening. They have four annual fairs, one of which is a much-frequented horse-fair. There are some public offices, an hospital, a workhouse and lunatic asylum, a church, and a free-school with five masters. The ducal palace, at Old Strelitz, having been destroyed by fire in 1713, the duke built a new one at a place called Ghenke, a short distance from it, and in 1733 founded New Strelitz, a very neat town, built in the form of a star, with eight rays diverging from the market-place in the centre. This town, which is now the residence of the duke and the seat of the principal government offices, has a gymnasium and several schools. The most remarkable edifice is the ducal palace, in which there is a library of 50,000 volumes, a cabinet of medals, and a very curious collection of German antiquities. The palace has a fine garden and an extensive park. The inhabitants, now near 6000, have no manufactures of any importance, and derive their subsistence chiefly from the expenditure of the court and the public offices, from handicrafts and agriculture. The environs of the town, which is situated on the Zirker lake, are very pleasant.

(Hassel; Stein; Hörschelmann; Hempel, *Beschreibung von Mecklenburg*.)

STRENGTH OF BEAMS AND OTHER MATERIALS. [MATERIALS, STRENGTH OF; ROOF.]

STREPSICERUS, Colonel Smith's name for the Koodoo. [ANTELOPE, vol. ii., p. 78.]

STRE'PSILAS. [SCOLOPACIDÆ, vol. xxi., p. 86.]

STREPTAXIS, Mr. J. E. Gray's name for a genus of pulmoniferous mollusks, separated from *Helix* on account of the eccentricity of the penultimate whorl.

Generic Character.—*Shell* ovate or oblong; subhemispherical in the young state, deeply umbilicated, and with the whorls rapidly enlarging. As the shell becomes complete, the penultimate whorl is bent towards the right and dorsal side of the axis, where the umbilicus becomes compressed, and often nearly closed. Aperture lunulate, border of the outer lip thickened and reflected; a single tooth often present on the outer side of the inner lip.

Example, *Streptaxis contusa*. [HELICIDÆ, vol. xii., p. 110.]

STREPTOSPO'NDYLUS, H. von Meyer's name for an extinct genus of reptiles belonging to the *Cœlospondylian tribe* of the *Crocodilian order* in the arrangement of Professor Owen, who thus defines the vertebral characters of this highly interesting form, the *Steneosaurus rostro-major* of Geoffroy, and the *Crocodile d'Honfleur* of Cuvier:—

'The distinguishing vertebral characters are a ball-and-socket articulation of the bodies of the vertebræ; but the positions of the ball and cavity are the reverse of those in the existing crocodiles, the convexity being on the anterior part of the vertebra, and the concavity directed backwards. In the anterior vertebræ, which have the ribs articulated with the body, there is a deep pit behind the costal articular surface; the transverse process rises by four salient ridges, one from each oblique process, and the two inferior and principal ones from the base of the neurapophysis; these ridges converge at an acute angle as they ascend, and meet at the under part of the transverse process, so as to include a triangular space, which is deeply concave. A third salient ridge ascends from the fore part of the base of the neurapophysis to the anterior oblique process, nearly parallel with the posterior of the two last-mentioned ridges, so that the side of each neurapophysis appears as if marked with the letter N in high relief. In the cervical and anterior dorsal vertebræ there are, instead of a single inferior spinous process, two ridges, which terminate each in front by a tubercle.'—(*Report on British Fossil Reptiles. British Association.*)

The Professor states that he is not aware that remains of this Crocodilian genus have hitherto been recognised in any of the British strata, and he proceeds to describe certain fossils found in the oolite in the vicinity of Chipping Norton, among which the anterior half of an anterior dorsal vertebra belonging to this animal, and in the collection of Mr. Kingdon of that town, is described as follows:—

'The articular surfaces for the ribs are, as usual, close to the anterior part of the body of the vertebra, and this terminates by a convex articular surface, instead of being, as in the Crocodiles, concave: the second character is the remarkably deep pit behind each of the costal articular surfaces. It is as if a man had pressed his two thumbs forwards and inwards up to the first joint, into the substance of the body of the vertebra, until their extremities had nearly met. The aperture of each pit measures one inch by ten lines. Sufficient of the neurapophysial arch is preserved to show the depression which has separated the two anterior ridges of its external surface; but these characteristic ridges, with the transverse spinous and oblique processes, are wanting. The medullary canal is compressed, and gives an oval vertical section one inch six lines high, and one inch two lines wide. Both upper and lower surfaces of the medullary canal are flat, and join the lateral surfaces at nearly a right angle. There is a slight ridge along each side of the medullary canal, indicating the neurapophysial suture, which extends here outwards and obliquely downwards to above the middle of the costal depression. This depression is vertically ovate, with a deeper oblique pit in the middle, two inches in the long diameter, by one inch six lines across the broadest part. The texture of this vertebra is coarsely cellular, except for about two lines at the margin, where it is in very compact laminæ. The anterior articular surface of the centrum is slightly and irregularly convex, being nearly flat at the upper part.

'There is a slight deviation from the symmetrical figure in the whole of this vertebral fragment. The body of the vertebra is much compressed in the middle, and suddenly expands to form the terminal articular surface. This character is likewise indicated by Cuvier in his *Crocodile d'Honfleur*;* thus the transverse diameters of the middle of the vertebral body, across which the present fossil has been fractured, measures two inches three lines, whilst the same diameter of the convex articular extremity is four inches.

'The corresponding diameters of one of the anterior dorsal vertebræ of the *Streptospondylus*, described by Cuvier, are respectively one inch seven lines, and two inches six lines; whence we may conjecture that the length of the entire vertebra here described would have been four inches and a half. The vertical diameter of the articular surface is three inches nine lines.

'The non-articular surface of the vertebral body is smooth, except near the articular extremity, where it is rather coarsely rugous. The inferior ridges and tubercles have disappeared at the part of the vertebral column to which the present vertebra has belonged.

'The osseous substance of the present fossil, like that of the bones of the *Streptospondylus* from Honfleur, present a deep chocolate-brown hue, and take a bright polish. It is not completely mineralized; the small cavities of a great part of the diploë are empty, and not filled with semitransparent calcareous spath, as in the Honfleur specimens.' (*Loc. cit.*)

We now proceed to the other fossils from the same locality recorded by the Professor:—

'With the portion of the vertebra above described there was associated the extremity of a spinous process, which gradually expands to a rough obtuse quadrilateral summit. This spine is characterised by having a very rugged and thick ridge, developed from the anterior and posterior surface of what may be regarded as the ordinary spinous process, the sides of which are smooth, except near the summit.

	Inches.	Lines.
'The length of this fragment of spine is	3	-
The transverse diameter of the base .	0	9
The transverse diameter of the summit of the apex	1	6
Antero-posterior diameter of spine :	1	3
Ditto, including the ridges . .	1	10

'The anterior and posterior ridges are narrower than the surface from which they rise.

'In the Crocodile a thin plate is continued from the anterior and posterior edges of the thicker spinous processes: but the *Streptospondylus* presents an extreme and peculiar development of this structure.

'A portion of a compressed, conical, hollow tooth, with a brown dense glistening dentine, resembling that of the *Megalosaurus*, was associated with the preceding vertebra. The length of this fragment is 2 inches 1 line, but both ends are wanting. The breadth is 8 lines; the thickness 5 lines.

'If it really belong to the *Streptospondylus*, it confirms the view of the affinity of that genus to *Megalosaurus*, which has been suggested by the characters of the vertebra. This tooth was found associated with the preceding fragment in the oolite at Chipping Norton. With these were likewise found a portion of a broad flat bone, with a convex, rough, articular labrum, nearly two inches thick, and of a fine cancellous structure, and fragments of long bones, with large medullary cavities and compact outer walls, of which the thickness equals about one-third of the diameter of the medullary canal.'

Professor Owen then notices a posterior dorsal vertebra from the jet-rock (lias shale) near Whitby (much more complete than the preceding specimen, and nearly corresponding in size with the dorsal vertebræ of the Honfleur *Streptospondylus* described by Cuvier), in the collection of Mr. Ripley of Whitby; and informs us that the third British formation in which he has determined the remains of the genus is the Wealden, specimens having been obtained from three localities, viz. Tilgate Forest, in Sussex, and Brook Point and Culver Cliff, in the Isle of Wight. The specimens, he observes, differ in size from those already described, being larger than the *Streptospondylus Cuvieri* from the oolite, and he strongly suspects that they indicate a different species, indeed he names it *Streptospondylus major*, but remarks that the means of comparison for the satisfactory establishment of the distinction are as yet wanting. Professor Owen also makes mention of a cervical vertebra associated, as in the Mantellian Collection, with vertebræ of the *Iguanodon* and *Cetiosaurus*, which and

* 'Le corps de cette vertèbre, ainsi que des suivantes est beaucoup plus rétreci dans son milieu que dans les Crocodiles ordinaires.'—*Ossem. Foss.*, [illegible] tom. v., pt. 2, p. 150.

been washed out of the submarine Wealden beds at the south side of the Isle of Wight, and thrown on shore near Culver Cliffs and Brook Point: this specimen is in the museum of Mr. Saull, of Aldersgate street, London. Some idea of the size of this reptile may be derived from Professor Owen's admeasurements, which give 5 inches as the transverse diameter of the posterior concave articular surface in the Wealden, and 6 inches in the Culver Cliff specimen, whilst the transverse diameter of the body across the inferior transverse processes is 8 inches in the Tilgate, and 6 inches 6 lines in the Culver Cliff specimen, the height of the latter from the lower surface of the centrum to the hind part of the base of the spine being 7 inches 9 lines.

The Professor further observes that the vertebra from the forest marble alluded to in the note at p. 297 of Dr. Mantell's 'Geology of the South-east of England' is a centrum from the posterior part of the dorsal region of the *Streptospondylus major*.

The foreign localities in which remains of *Streptospondylus* have been found are the Oxford clay formation at Honfleur, and the Kimmeridge-clay at Havre (Cuv.); and the lias of Altdorf (H. von Meyer).

We have called the form of this extinct Saurian highly interesting, for it presents those transitional characters which, while they beautifully manifest the passage, so to speak, from one specific form to another, are too apt to lead a superficial observer to wild speculations. Professor Owen, in his luminous argument at the close of the valuable Report above quoted, against the transmutation theory—fallacy, we would venture to call it—of Maillet, Lamarck, and their followers, observes that if the three forms of extinct Saurians, *Ichthyosaurus*, *Plesiosaurus*, and *Teleosaurus*, whose changes of specific and generic characters have thus been speculated upon, had actually succeeded each other in strata successively superimposed in the order here set forth, some colour of probability might attach itself to this hypothesis, and there would be ground for searching more closely into the anatomical and physiological possibilities of such transmutations. Those genera however, he observes, appeared contemporaneously on the stage of vital existence: one neither preceded nor came after the other. How the transmutation theory is to be reconciled to these facts is not, he justly observes, obvious, nor to these other, viz. that the Teleosaur ceases with the oolite, while the Ichthyosaur and Plesiosaur continue to co-exist to the deposition of the chalk, and disappear together alike unchanged; the Ichthyosaur manifesting as little tendency to develop itself into a Plesiosaur as this to degrade itself into the more fish-like form of the Enaliosaurian type.

'If,' continues the Professor, 'it were urged that the *Streptospondylus*, or crocodile with ball-and-socket vertebræ, of which the remains occur in later secondary strata, when the Teleosaur had ceased to exist, might be a modification of the apparently extinct amphicœlian crocodile, in which the vertebræ had undergone a progressive development analogous to that by which the biconcave joints of the vertebræ of the tadpole are actually converted into the ball-and-socket joints of those of the mature frog, the facts of both geology and anatomy again oppose themselves to such an hypothesis; for the remains of the *Streptospondylus* occur likewise in the Whitby lias, which is the earliest formation characterized by remains of the *Teleosaurus*; and the modification of the vertebral structure by which the *Streptospondylus* differs from its antient contemporary, and which it retains unaltered throughout the whole series of oolitic strata, is no approximation to the ball and-socket structure of modern crocodiles, which first appears in the *Mosasaurus* and the Eocene crocodiles, but is the very reverse. As reasonably might we infer that the Teleosaur was an intermediate form between the *Streptospondylus* and modern crocodiles, and that the anterior ball had first subsided, and a sub-biconcave type of vertebræ had been produced before the posterior ball which characterizes the vertebræ of recent crocodiles was finally developed. If the present species of animals had resulted from progressive development and transmutation of former species, each class ought now to present its typical characters under their highest recognised conditions of organization; but the review of the characters of fossil reptiles taken in the present Report proves that this is not the case. No reptile now exists which combines a complicated and thecodont dentition with limbs so proportionally large and strong, having such well-developed marrow-bones, and sustaining the weight of the trunk by synchondrosis or anchylosis to so long and complicated a sacrum, as in the order *Dinosauria*. The Megalosaurs and Iguanodons, rejoicing in these undeniably most perfect modifications of the Reptilian type, attained the greatest bulk, and must have played the most conspicuous parts in their respective characters as devourers of animals and feeders upon vegetables that this earth has ever witnessed in oviparous and cold-blooded creatures. They were as superior in organization and in bulk to the crocodiles that preceded them, as to those which came after them.'

There is not the slightest ground for affirming that the procœlian gavial of the present day is in any respect more highly organised than the opisthocœlian gavial of the oldest lias. If the differences of vertebral structure in these Crocodilians were contrasted in reference to their relative approximation to the vertebral structure of the higher animals, the resemblance of the ball and socket joints of the spine of the *Streptospondylus* to those of certain mammals would give precedence in organic perfection to the primæval gavial. If therefore the extinct species, in which the Reptilian organization culminated, were on the march of development to a higher type, the *Megalosaurus* ought to have given origin to the carnivorous mammalia, and the herbivorous should have been derived from the *Iguanodon*. But where is the trace of such mammalia in the strata immediately succeeding those in which we lose sight of the relics of the great Dinosaurian Reptiles; or where indeed can any mammiferous animal be pointed out whose organization can by any ingenuity or licence of conjecture be derived, without violation of all known anatomical and physiological principles, from transmutation or progressive development of the highest reptiles? If something more than a slight inspection be bestowed upon the organic relics deposited in the crust of the globe, we learn that the introduction of mammalia on that crust is independent of the appearance of the highest forms of reptiles. The small insectivorous mammals of the lower oolite* are contemporary with the most antient Dinosaur, and are anterior to the *Iguanodon*. The period when the class of reptiles flourished under the widest modifications, in the greatest number, and of the highest grade of organization, is passed: and since the extinction of the Dinosaurian order it has been declining. The *Reptilia* are now in great part superseded by higher classes. Pterodactyles have given way to birds; Megalosaurs and Iguanodons to carnivorous and herbivorous mammalia; but the sudden extinction of the one and the abrupt appearance of the other, are alike inexplicable on any known natural causes or analogies.'

Our limits will not allow us to quote more of this well digested argument, to which we refer those who are interested in this inquiry; but we must not omit the following propositions laid down by Professor Owen in the course of the discussion:—

'The fossil reptiles, like the fossil fishes, approximate nearest to existing species in the tertiary deposits, and differ from them most widely in strata whose antiquity is highest.

'Not a single species of fossil reptile now lives on the present surface of the globe.

'The characters of modern genera cannot be applied to any species of fossil reptile in strata lower than the tertiary formations.

'No reptile with vertebræ articulated like those of existing species has been discovered below the chalk.

'Some doubt may be entertained as to whether the *Ichthyosaurus communis* did not leave its remains in both oolitic and cretaceous formations; but with this exception no single species of fossil reptile has yet been found that is common to any two great geological formations.

'The evidence acquired by the researches which are detailed in the body of this Report permits of no other conclusion than that the different species of reptiles were suddenly introduced upon the earth's surface, although it demonstrates a certain systematic regularity in the order of their appearance. Upon the whole they make a progressive approach to the organization of the existing species, yet not by an uninterrupted succession of approximating steps. Neither is the organization one of ascent, for the reptiles have not begun by the type of organization by which at the present day they most closely approach fishes; nor have

* *Thylacotherium* and *Phascolotherium*. [Marsupialia, vol. xiv, p. 454, et seq.]

they terminated at the opposite extreme, where we know that the reptilian type of structure made the nearest approach to birds and mammals.

'Thus, though a general progression may be discerned, the interruptions and faults, to use a geological phrase, negative the notion that the progression has been the result of self-developing energies adequate to a transmutation of specific characters; but on the contrary support the conclusion that the modifications of osteological structure which characterise the extinct reptiles were originally impressed upon them at their creation, and have been neither derived from improvement of a lower, nor lost by progressive development into a higher type.'

STRETTON. [SHROPSHIRE.]

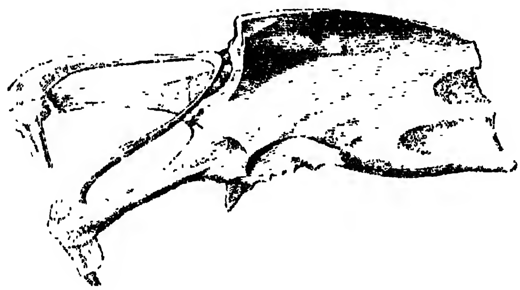
STRIGATELLA. [VOLUTIDÆ.]

STRIGIDÆ [OWLS, OWL TRIBE], the family name for the nocturnal birds of prey, the *Ægolians* of Vieillot.

This natural family have large heads and great projecting eyes directed forwards, and surrounded with a circle or disk (more or less developed according to the nocturnal or comparatively diurnal habits of the species) formed of loose and delicate feathers; a raptorial beak; crooked claws; and a downy plumage, generally spotted, powdered, or barred with different shades of brown and yellow.

ORGANIZATION.

Mr. Yarrell, in his paper on the *Anatomy of Birds of Prey* (*Zool. Journal*, vol. iii.), points out the diminished extent of surface and power in the sternum of the Owls as compared with that of the Peregrine Falcon. [FALCONIDÆ, vol. x., p. 163.]

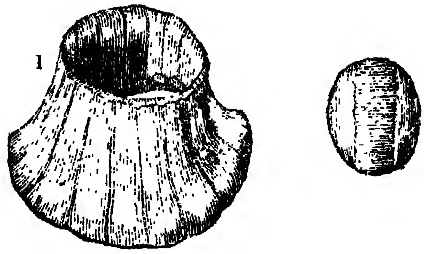


i Owl, Strix Stridula. (Yerell.)

A ... s, that from the loose and soft nature of ... in these birds, as well as their deficiency in ... and bone, rapid flight is denied them as useless, if not dangerous, from the state of the atmosphere at the time they are destined to seek their food; but, he adds, they are recompensed for this loss, partly by their acute sense of hearing, from an extension of the posterior edge of the cranium forming a conch, coupled with a very large external orifice; and partly by the beautifully serrated exterior edge of the wing primaries, which, allowing them to range without noise through the air, enables them to approach unheard their unsuspecting victim, which falls a prey to the silent flight and piercing eye of an inveterate enemy. He further remarks, that some increase and variation will be found in the strength and form of such of the owls as depart from the type of the true nocturnal bird. In the snowy owl and short-eared owls, which are described as occasionally taking their food by day, the furcula, Mr. Yarrell observes, is stronger and less angular in proportion than in the wood and barn owls. The trachea, he tells us, of the different species of owls so nearly resembles the same part in the falcons, that a separate description is unnecessary, and the same may be said generally of the œsophagus, stomach, and intestines, as the similarity of food would appear to require. Mr. Yarrell found the two cœcal appendages ...siderably developed in the species of Strix; in the Barn ...wl (*Strix flammea*), as well as in the Short-eared owl, they are, he states, small at their origin, afterwards dilated, and each 1¾ inch in length. The crop is large, and the stomach or gizzard is considerably muscular notwithstanding the nature of their living prey.

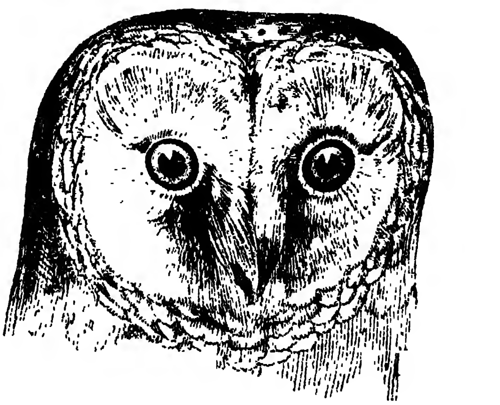
Brain, Nervous System, and Senses.—The brain is well developed in this family, and the senses of sight, hearing, taste, and smell, especially the two former, are enjoyed in a considerable degree of perfection.

Sight.—Mr. Yarrell observes (*loc. cit.*) that the external form of the bony ring in the Golden Eagle [FALCONIDÆ, vol. x., p. 165] will be found to extend through all the species of every genus of British birds, except the owls, in all of which it is concave. The bony ring of the Snowy Owl has fifteen plates forming the circle, and they are considerably lengthened. The transparent cornea being placed as it were at the end of a tube, is thus, he remarks, carried forward beyond the intervention of the loose and downy feathers of the head.



1, Bony ring of a S... anterior surface, less ... 2, Crystalline le... of the same bird, a, the ... an the posterior one. (Yarrell.)

It is this position of the eyes, observes the same author, giving a particular fulness and breadth to the head, which has gained for the owl the intellectual character universally awarded to it. The concave facial disk of feathers with which they are surrounded materially aids vision by concentrating the rays of l...

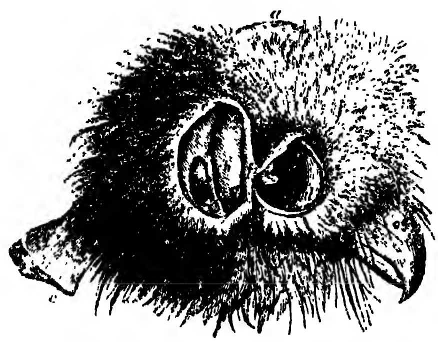


Mr. Yarrell goes on to observe, that the extent of vision enjoyed by the Falcons is probably denied to the Owls, but their more spherical lens and corresponding cornea give them an intensity better suited to the opacity of the medium in which their power is required to be exercised. 'They may be compared,' says he, 'to a person near-sighted, who sees objects with superior magnitude and brilliancy when within the prescribed limits of his natural powers of vision, from the increased angle these objects subtend.'

In the museum of the Royal College of Surgeons in London, No. 1755 of the *Physiological series* of preparations, is the eye of the Great Horned Owl (*Bubo maximus*), from which the cornea, humours, and a lateral section of the tunics have been removed, showing the remarkable prolongation of the anterior segment of the eye, which assumes in consequence a tubular form. The horny plates of the sclerotica are coextended with this segment to maintain its peculiar shape, and to afford a firm basis for the support of a very large and prominent cornea. The marsupium may be observed to be of small proportional size, consisting of seven slightly converging plicæ. The sclerotica, forming the posterior segment of the eye, is very thin. The vitreous and crystalline humours of the eye of the same species are prepared in No. 1749 of the same series, to show that the vitreous humour has a distinct capsule, part of which is reflected from its outer surface. No. 1750 is the crystalline lens of an owl, showing its great convexity adapted to the small distance at which objects are visible to this nocturnal bird at the time when it goes in quest of food. A longitudinal section of the crystalline lens of an owl, showing its f...m and laminated structure, is prepared in No. 1751. No. 1798 shows the eyeball (*membrana nictitans*) and its muscles, with the external eyelids and Harderian gland

of the Great Horned Owl. In consequence of the limited motion of the eyeball, arising from its bulk as compared with the orbit, the muscles are of small size. Those of the *membrana nictitans* are, on the contrary, well developed. Bristles are placed in the puncta lachrymalia, and in the duct of the Harderian gland. No. 1799 is the right side of the head of the Horned Owl (*Otus auritus*), showing the three eyelids in situ. The two horizontal are provided with plumose cilia; the third, or nictitating eyelid, is more obliquely placed in the owls than in other birds, and sweeps over the eye downwards as well as outwards, in which motion it is usually accompanied by the upper eyelid. The tarsal cartilage is nevertheless found only in the lower eyelid. A white bristle is passed through the duct of the Harderian gland, and a black one through one of the puncta lachrymalia and the lachrymal duct to the nose. (*Catalogue*, vol iii.)

Hearing.—This sense appears to be very acute in the *Strigidæ*: they not only look, but listen for prey. No. 1581 of the same series, in the same museum, is a section of the head of the last-mentioned species, showing the organ of hearing of the right side. The membrana tympani is lodged, in this tribe of birds, at the bottom of a wide but moderately deep external meatus, which is guarded by an anterior fold of integument, and further provided with a well developed auricular circle of feathers, which together fulfil the functions of an external concha. The drum of the ear is very thin and transparent; its vibrations are conveyed to the labyrinth by a single ossiculum, as in reptiles. The membrane closing the foramen ovale, to which the basis of the columella is attached, the vestibule, and the three semicircular canals, are shown; the two smaller and external canals are laid open where they open into each other in the middle of their course. Bristles are placed in both Eustachian tubes, which communicate together at their nasal terminations, as in the crocodile.



Head of a young White or Barn Owl. (Strix flammea.)

The down pressed backwards and forwards to expose the auditory passage and operculum. *a*, cranium; *b*, bill perforated by the nostril; *c*, neck; *d*, eye; *e*, termination of external skin surrounding the orifice of the ear; *f*, anterior flap, or opercular fold of the ear; *g*, part of the tympanic or quadrate bone; *h*, membrana tympani. (*Cat. Mus. Coll. Chir.*, vol iii.)

Foot of White or Barn Owl. (Strix flammea.)

Smell and Taste.—These senses appear to be developed nearly as they are in the *Falconidæ*. No. 1481 of the series in the same museum shows the tongue, larynx, and lower jaw of a horned owl injected. The tongue exhibits little vascularity, except at the membranous space intervening between the retroverted papillæ on its base and the glottis. The orifices of numerous glands may be observed on each side of the frænum linguæ. (*Catalogue*, vol. iii.)

Touch much the same as in the *Falconidæ*. Like theirs, the feet of the owls are formed for clutching and trussing their prey, in aid of which the external toe of the latter is capable of being directed either forward or backward.

Systematic Arrangement and Natural History.

Zoologists are generally agreed in the position assigned to the owls. In Belon and Gesner we find them next to the diurnal birds of prey. In the Work of the former the cuckoo indeed intervenes; but the external similitude between that species and the birds of prey accounts for the intervention. In Gesner the Shrikes come between the diurnal and nocturnal predacious birds.

Willughby divides the birds of prey into the diurnal and the nocturnal, placing in the last subdivision of the former the Butcher-Birds and Birds of Paradise. The latter he separates into two sections,—1, the horned or eared; 2, those without horns.

Brisson places the owls in the second section of his third order, which consists of birds with a short and hooked bill. This second section is defined as comprising species the base of whose bill is covered with feathers directed forwards.

The genus *Strix* stands among the *Accipitres* in the 'Systema Naturæ,' between the genera *Falco* and *Lanius*, which last concludes that order of Linnæus.

Latham places the owls at the end of the birds of prey, and so do Lacépède, Duméril, and Meyer. Illiger, on the contrary, makes the *Nocturni* the first of his order *Raptatores*. Cuvier makes them follow the *Diurnes*; and they immediately precede the *Passereaux*, among which last the Butcher-birds hold the first place in the first family, *Dentirostres*. Vieillot arranges the owls with the family name of *Ægolians*, under his second tribe (*Nocturni*) of his first order *Accipitres*.

M. Temminck places them at the end of his first order (*Rapaces*); and, in his 'Manuel' of European birds, divides the family of Owls into two divisions,—1st, the *Chouettes*, properly so called; 2nd, the *Chouettes Hibous*.

The 1st division, or *Chats-huants*, he subdivides into two sections, placing in the first section the *Accipitrine Owls*, or those which see well and pursue their prey by day; and in the second section the *Nocturnal Owls*, which hunt in no light stronger than twilight or moonlight, and conceal themselves during the day.

In the first section of the first division M. Temminck places the following species– *Striges Lapponica, Nyctea, Uralensis*, and *funerea*.

In the second we find *nebulosa, Aluco, flammea, passerina, Tengmalmi*, and *Acadica*.

Under the second division, *Chouettes Hibous*, distinguished by two tufts of feathers situated more or less forward upon the front, and capable of erection (whence their English appellation of Horned Owls) he arranges *Striges brachyotus, Bubo, Otus*, and *Scops*.

Mr. Vigors, who makes his first order (*Raptores*) consist of the families *Vulturidæ, Falconidæ, Strigidæ*, and *Gypogeranidæ*, says, in his paper 'On the Natural Affinities that connect the Orders and Families of Birds,' that if we search for the connection between the *Falconidæ* and the *Strigidæ*, we shall not fail to find their affinity apparent, as is usual, in the less typical part of the two groups. 'In the latter family some species may be observed gradually approaching the *Falcons* in their diurnal habits and the lateral position of the eyes; and, at the same time, deserting their own congeners in losing the large orifice to the ear, the disk that surrounds the face, and the egrets that decorate the head of the type of the family. The genus *Surnia*, Dumér., which includes the "*Chouettes Eperviers*" of the French naturalists, is the most accipitrine of the group. In addition to the approximation already pointed out, the bill and tail of this genus, more lengthened than those of the *Owls* in general, give it a still stronger resemblance to the *Falconidæ*. The group of *Buzzards* among the latter family appears to come most closely to the *Owls* in their slow and heavy

flight, the softness of their plumage, and their slothful and cowardly habits. The genus *Circus* of Bechstein in particular, of which our *Hen Harrier* gives a familiar example, may be observed to possess a peculiar elongation and erection of the face-feathers, which bears some resemblance to the disk that encircles the face of the *Strigidæ*, and it may therefore be particularised from among those groups, at least, which are most known to us, as exhibiting the nearest approach to *Surnia*.'

The same author observes, in the same paper, that when we search among the *Perchers* [INSESSORES] for that point where they approximate the *Owls*, we find in the *Caprimulgus* of Linnæus [GOATSUCKERS] a group whose general appearance and habits point out the affinity. 'The nocturnal and predatory manners of this genus, the hawking flight, the legs feathered to the talons, the large ears and eyes, the very disk that surrounds the face, and the pectination of the external quill-feathers, observable in some of the species, the general softness of the plumage, together with its peculiarly striking colour and markings, produce a similarity between it and *Strix* that has attracted the eye of the common observer no less than of the naturalist. The provincial names of this genus have generally a reference to this resemblance; while the earlier scientific describers of the different species have for the most part ranked them with the *Owls*. I know not whether the singular character observable in some of the species of this family, the serrated nail of the middle toe,* may not be cited as an additional proof of their approach to the *birds of prey*. The strong talons of the latter are lost in *Caprimulgus*; but a construction of similar import (for the serration of the nail appears capable of being applied to the purposes of seizure only) preserves, though faintly, the resemblance. May we not almost venture to affirm that this apparently trivial appendage is an instance of that beautiful shading by which Nature softens down the extremes of her neighbouring groups, one of those minute and delicate touches by which she marks at once an affinity and deviation? But while we may discern at a glance the general approximation of these two families, we must at the same time acknowledge that they stand in need of an intermediate link to give them a closer connection. The weakness of the bill and of the legs and feet of the *Caprimulgus* still keeps it at some distance from the *Owls*, in which the same members are comparatively strong, while the wide gape of its mouth serves to divide the families still further. A connecting link has been however supplied by an Australasian group, *Podargus* of M. Cuvier, which harmonises these discrepant characters. We have an opportunity of observing, among the specimens in the collection of the Society, how far the bill of this extraordinary genus combines the different forms of that of the two genera, and how far the legs, still maintaining the characteristics of *Caprimulgus*, such as the unequal length of the toes, are related to those of *Strix* by their superior robustness. Here indeed there is a beautiful gradation of affinities. All the front toes of *Caprimulgus* are united by a connecting membrane as far as to the first joint; those of *Strix* are divided to the origin; while those of *Podargus* partake of the characters of both, in having the middle toe connected with the outer, but divided from the inner. Again, as I have already remarked, *Caprimulgus* has the nail of the middle toe dilated and serrated, *Strix* has it, generally speaking, undilated and entire at the margin; but in *Podargus* the same part displays the singular dilatation of the one, and the marginal integrity of the other. It is difficult to say to which of these groups it comes nearest, until further and more accurate accounts than we at present possess of its food and economy may determine its actual situation. At present it remains osculant between the two families, and may decidedly be pronounced the immediate passage from the *birds of prey* to the *Perchers*.' (*Linn. Trans.*, vol. xiv.) In the 'Portraits d'Oyseaux,' 1657, the *Strix Caprimulgus*, *Fur nocturnus* (Goatsucker), immediately follows the *Owls*.

Mr. Swainson states that the divisions of the *Strigidæ* made by modern ornithologists can all be referred to one or other of the following groups:—1, Typical *Owls*, having the facial disk very large and complete, with large ears and (in general) an ample operculum; 2, Horned *Owls*, furnished with egrets and a large facial disk, but having only small or moderate-sized ears; and 3, *Diurnal* or *Hawk Owls*, where the conch of the ear is comparatively small, and is destitute of an operculum: the head has no egrets, and the facial disk is imperfect or obsolete. The first he considers the typical group; the second, the subtypical; and the third, the aberrant group.

The *Striginæ*, or typical owls, are, Mr. Swainson thinks, well represented by the common white species. The head is, he remarks, uncommonly large, and the facial disk of great circumference; the extent of the latter is marked by a dense semicircle of rigid narrow feathers, forming a sort of collar, with turned ends, lying close upon each other in the manner of scales. The aperture of the ear, which is within this collar, is large, measuring, he says, in the Brown Owl, more than an inch in length. This is protected by an operculum, which is sometimes much larger (as in *Strix flammea*) than the aperture, and sometimes nearly of the same size. He does not however regard these differences as *generic*. Owls of this group are, he observes, eminently nocturnal, and their geographic distribution, as is usual in all pre-eminent types, is very wide; the white owl, under slight variations of colour, having been found in all the temperate parts of America, in the sultry groves of India, and even in Australia. Without attempting to arrange the subgenera of this group in their natural order of succession, a task, he remarks, of great difficulty, he proceeds to enumerate such of the subordinate groups as appear to him either to lead to or represent the other genera. He makes it the primary distinction of the birds of this group, that two out of the three primary characters, viz. the facial disk, the operculum, and the great development of the ear, should be found in all; hence he includes in it the common long and short-eared owls of Britain, as aberrant forms or subgenera, representing the rasorial or crested type of the genus. Mr. Swainson finds a third type in the *Strix Tengmalmi*, to which, he thinks, we should probably refer the various small species of Europe (still but imperfectly known under the name of *Strix passerina*), together with those of temperate America. These latter owls, he observes, are known by their small size; short feet, thickly covered with feathers to the root of the claws; and by the operculum being long and narrow, the conch forming almost a semicircle. This he considers to be the tenuirostral division of the genus, and gives it the subgeneric appellation of *Scotophilus*. *Strix cinerea*, with its long tail, holds, in his opinion, an intermediate station between *Strix Tengmalmi* and *Strix stridula*, and becomes the type of his subgenus *Scotiaptex*, the length and graduated shape of the tail separating it both from *Scotophilus* and *Strix*.

Mr. Swainson retains the antient name of *Asio* for the second genus, remarking that *Noctua* has already been appropriated by Linnæus to an extensive group of nocturnal lepidopterous insects. Here he places the true Horned Owls, furnished with conspicuous egrets above the eyes, and with large disks and ears. The facial disk, in this group, is still large, but it is, he observes, more or less imperfect, especially above the eyes. The grand character of this division is the possession of egrets. Mr. Swainson has little doubt, judging from published figures, that all the subgeneric groups exist, but he here notices two only. The Great White Horned Owl (*Heliaptex Arcticus*), in his opinion, evidently intervenes between *Asio Virginianus* and *Nyctea candida*. 'It is, in fact,' continues Mr. Swainson, 'so closely connected with the latter, that, but for its egrets, both would stand in the same genus: the facial disk has now almost entirely disappeared; the head is not much bigger in proportion than that of a falcon of the same dimensions; and the ears are very small. Like the Great Cinereous Owl, which it seems to represent, its tail, although not much graduated, is longer than usual. Last of all come the little *Scops* Owls, a diminutive group in point of size, but of which there are many species. We are disposed to believe that these may form a subgenus of themselves, although we cannot at present detect any very prominent character by which they are separated from their congeners. They seem to differ indeed from the great horned owls above mentioned, by the superior length of their legs, and by the nakedness of their toes. From the hornless passerine owls of Europe (*Strix Tengmalmi*, &c.), which they seem to represent, they are at once known by the diminished size of their ears, and by their egrets; while, from the corresponding group in South America (*Nyctipetes*)

* 'The common *Barn-Owl* (*Strix flammea*, Linn.) possesses the same character of a serrated *unguis*, and some other species of the *Strigidæ* exhibit somewhat the rudiments of it, thus establishing still more closely the affinity of the groups under consideration.'

they are immediately recognised by the last of these characters. For the present therefore we may retain the group until the whole genus is properly analysed. Several species, apparently belonging to the subgenus *Scops*, are found in South America, and one in Western Africa. One of the most remarkably horned species is the *Asio superciliosus;* and there are several from India which have the *tarsi* or legs nearly naked.'

Mr. Swainson then comes to the aberrant group, composed, as usual, of three divisions, which he views as genera. In this group he places *Nyctea*, *Nyctipetes*, and *Surnia*.

Mr. Swainson rejects the genera *Noctua*, *Bubo*, and *Ulula*, and still hesitates at admitting *Syrnium*, being uncertain whether the brown owl [illegible] is really one of the types of the genus *Strix*. On the other hand he proposes *Scotiaptex*, *Scotophilus*, *Heliaptex*, and *Nyctipetes*.

In the following table the author gives his arrangement of the entire family:—

Strigidæ.—*The Owls.*

		Genera.
1. Typical group.—	Ears large, operculated, no egrets.	Strix.
2. Subtypical.—	Ears smaller, no operculum, egrets.	Asio.
	Ears small, no egrets or operculum, disk imperfect.	
Aberrant.—	Head small, claws feathered, tail short.	Nyctea.
	Head large, claws naked, tail moderate.	Nyctipetes.
	Head small, claws feathered, tail wedged. . . .	Surnia.

The same author observes that we know too little of the birds composing these groups to admit of their analogies being traced among other families, at least with precision. Nevertheless, he notices the indications of such analogies. 'Thus,' says he, 'the lengthened and more conic bill of the barn owl reminds us of the *Conirostres;* on the other hand the bill of *Asio Virginiana* (Virginianus) is described by Dr. Richardson as very strongly curved from the base, and with its cutting margin very obtusely lobed in the middle—a structure peculiarly belonging to dentirostral types. The short tail and piscatorial habits of the *Nyctea candida* sufficiently designate the aquatic type. The long-legged burrowing owl obviously represents the grallatorial order of birds and the gliriform quadrupeds; but whether it is the type of *Nyctipetes*, or one of its subgenera, we know not; while in the long-tailed hawk-owls of the genus *Surnia* we trace that great development of tail so conspicuous in rasorial types.' (*Classification of Birds*, vol. i.)

The following is the arrangement in the *Synopsis* at the end of the second volume of the work:—

Strigidæ.

Genera.

Strix, Linn. (Typical Owls.)

Subgenera:—*Strix; Scotiaptex; Scotophilus; Otus.*

Asio, Antiq. (Horned Owls.)

Subgenera:—*Heliaptex; Scops.* (Scops Owls.)

Nyctia, Sav. (Eagle Owls.)

Subgenera not defined.

Nyctipetes, Sw. (Sparrow Owls.)

Subgenera not defined.

Surnia, Dum. (Hawk Owls.)

Subgenera not defined.

The Prince of Canino, in his *Geographical and Comparative List of the Birds of Europe and North America*, gives the following arrangement of the—

Strigidæ.

Subfam. *a.* Surninæ.

Genera.—Surnia, Dum.; *Nyctea*, Bonap.; *Glaucidium*, Boie: *Athene*, Boie (*Nyctipetes*, Sw.); *Scops*, Sav.

Subfam. *b.* Buboninæ.

Genera.—Bubo, Cuv. (*Asio* and *Heliaptex*, Sw.); *Syrnium*, Cuv. (*Scotiaptex*, Sw.).

Subfam. *c.* Ululinæ.

Genera.—*Otus*, Cuv.; *Brachyotus*, Gould, *Ulula*, Cuv.; *Nyctale*, Brehm (*Scotophilus*, Sw.).

Subfam. *d.* Striginæ.

Genus, *Strix*, Linn.

The *Strigidæ* form the third family of the order *Accipitres* in the Prince's method. The *Falconidæ* compose his second family of that order. His fourth family, the first in his order *Passeres*, consists of the *Caprimulgidæ*.

Mr. G. R. Gray makes the *Accipitres Nocturni* the second suborder of his first order *Accipitres*. His third family, the first of that suborder, is formed of the *Strigidæ*, which are thus subdivided by him:—

Subfam. 1. Surninæ.

Genera.—*Surnia*, Dum. (*Syrnia*, Steph., *Strix*, Gm.); *Accaba*, Wagl. (*Surnia*, Cuv., *Strix*, Shaw); *Nyctea*, Steph. (*Noctua*, Cuv., *Nyctia*, Sw.); *Athene*, Boie (*Nyctipetes*, Sw., *Strix*, Daud.); *Huhua*, Hodgs.

Subfam. 2. Buboninæ.

Genera.—*Scops*, Sav. (*Scops*, Sav., *Asio*, Briss., *Otus*, Less., *Strix*, Linn.); *Lophostrix*, Less., *Ketupu*, Less. (*Cultrungius*, Hodgs., *Strix*, Gm.); *Bubo*, Sibb. (*Feliceps*, Barr., *Asio*, Antiq., *Ulula*, Bonap., *Heliaptex*, Sw., *Ascalaphus*, J. Geoff., *Strix*, Linn.)

Subfam. 3. Ululinæ.

Genera.—*Syrnium*, Sav. (*Scotiaptex*, Sw., *Ulula*, Briss., *Strix*, Linn.); *Otus*, Ray (*Asio*, Briss., *Brachyotus*, Gould, *Strix*, Linn.); *Urrua*, Hodgs.; *Nyctalops*, Wagl.; *Ulula*, Cuv. (*Strix*, Gm.): *Glaucidium*, Boie (*Strix*, Linn., *Noctua*, Cuv., *Athene*, Boie): *Nyctale*, Brehm (*Scotophilus*, Sw., *Nudipedes* et *Ptilipedes*, Less., *Strix*, Bechst., *Athene*, Boie); *Ninox*, Hodgs.

Subfam. 4. Striginæ.

Genera.—*Strix*, Linn; *Pholidus*, J. Geoff. (*Strix*, Horsf.); *Bulaca*, Hodgs.

Geographical Distribution of the Family.—Very wide; extending as high as the Polar Sea, where *Strix Nyctea* is recorded by E. Sabine as having been seen on the islands in the summer months, and by James Ross as having been observed about Victoria Harbour throughout the winter, where several pairs had bred in the preceding autumn; and as low at least as Port Famine in the Straits of Magellan (*Strix rufipes*, *Strix nana*, &c., King). Species are found in Europe, Asia, Africa, America, and in Australia.

Food. Birds and quadrupeds, and even fish (in the case of *Strix nyctea* and *Strix flammea*), according to the size of the species. Hares, partridges, grouse, and even the turkey, are attacked by the larger horned owls of Europe and America: while mice, shrews, small birds, snakes, and crabs suffice for the inferior strength of the smaller *Strigidæ*. Mr. Yarrell states that the short-eared owl (*Strix brachyotus*) is the only bird of prey in which he ever found the remains of a bat.

The species are numerous, and the British Museum contains a very fine collection of them. Our limits will not permit us to do more than notice a very few. The larger horned owls are described in the article BUBO.

EUROPEAN OWLS.

The common white or barn owl (*Strix flammea*) claims our first attention, from its typical nature.

Description.—*Male.*—Upper parts bright yellowish, varied with grey and brown zig-zag lines, and sprinkled with a multitude of small whitish dots, face and throat white; lower parts in some individuals rusty white, sprinkled with small brown dots; in others bright white, marked with small brownish points; in others again without the slightest appearance of spots; feet and toes covered with a very short down, more scanty on the toes; iris yellow. Length about thirteen inches.

In the *Female* all the tints are brighter, and more developed.

Young.—Covered with a thick white down, and remain long in the nest. Mr. Blyth states that the first set of feathers grows very slowly, and is not moulted till the second autumn.

Varieties.—Whitish, or entirely white.

This is the *Effraie*, *Fresaie*, and *Petit Chathuant Plombé* of the French; *Barbagianni*, *Alloco Commune e Bianco*, of the Italians; *Schleierkauz*, *Perlschlierkautz*, and *Perl-Eule* of the Germans; *De Kerkuil* of the Netherlands; *Barn Owl*, *White Owl*, *Church Owl*, *Gillihowlet*, *Howlet*, *Madge Howlet*, *Madge Owl*, *Hissing Owl*, and *Screech Owl* of the modern British; and *Dylluan wen* of the antient British.

Geographical Distribution.—Very wide. Common in England and Ireland, less common in Scotland. Not common in the Orkneys, but present in some of the islands. Found in Denmark, but said not to inhabit Sweden or Norway; generally spread over temperate Europe; found in Madeira; common in Loraine; extending in Africa from the north to the Cape of Good Hope; met with in India, Japan, and Australia?* African and Japanese individuals

* See post p. 122.

are, M. Temminck tells us, precisely similar to those of Europe; and those of North America (where it is found in the United States, but does not appear to visit the Fur-countries) differ only in having some slight tints of more sombre hue. Those of South America (the *Yellow Owl*) are different.

Habits, Food, &c.—Montagu says that this species is never known to hoot. Mr. Yarrell states that it screeches, but does not *generally* hoot. Sir W. Jardine declares that he shot one in the act of hooting; and that at night, when not alarmed, hooting is their general cry. It snores and hisses, and, like other owls when annoyed or frightened, snaps its bill loudly. Rats, mice, shrews, young birds, and beetles form their food, and the mice especially suffer when the white owl has a young brood to sustain. It has been seen to catch fish. This owl frequents churches, old buildings, and barns, often breeding in the latter, as well as in hollow trees near farmyards and villages. The nest is but a rough one, and the female lays three or four white eggs more oval than those of the brown or ivy owl, and not so large. Young have been found so late as July, September, and even December. Mr. Blyth, in the *Field Naturalist's Magazine* (vol. i.), throws some light upon this. 'A nest of the barn owl, last summer,' says he, 'in this neighbourhood (Tooting) contained two eggs, and when these were hatched two more were laid, which latter were probably hatched by the warmth of the young birds; a third laying took place, after the latter were hatched, and the nest at last contained six young owls of three different ages, which were all reared.' Mr. Yarrell states that he has frequently been told by boys in the country, that they had found eggs and young birds at the same time in this bird's nest. The food is generally swallowed whole, and the bones and fur or feathers rejected in pellets called castings, as indeed is generally the case with this family.

In captivity the Barn-Owl is sociable with other birds, but will sometimes, like the dogs, hide what remains of its meat.

Strix flammea.

Surnia Uralensis.—*Description.*—Face whitish, tail much graduated, much longer than the wings; all the plumage striped with large longitudinal spots and streaks.

Old of both Sexes.—Head of considerable size, face very large, well feathered, greyish white, marked with some blackish hairs; a large circle of white feathers spotted with brownish black, takes its origin on the forehead and frames in the whole face; top of the head, nape, back, and wing-coverts marked with great longitudinal spots, which are disposed on a whitish ground; throat, front of the neck, and all the lower parts whitish, marked on the middle of each feather with a large longitudinal brown stripe; quills and tail-feathers banded with brown and dirty white alternately; seven of these bands may be counted on the tail; beak yellow nearly hidden in the long hairs of the face; iris brown, tarsi and toes covered with white hairs marked with small brown points; claws very long, yellowish. Length of tail ten inches and some lines; total length about two feet.

Young of the Year.—All the ground-colour of the plumage bright brownish-grey; the spots and stripes on all the lower parts ashy-brown; upper parts irregularly spotted with ashy-brown and light red, and variegated with oval white spots; wings and tail transversely banded with grey the seven bands of the tail whitish ash.

This is the *Strix Uralensis* of Pallas; *Strix liturata* Retz; *Strix macroura*, Natterer; *Strix macrocephala* Meisner; *La Chouette des Monts-Urals*, Sonnini; *Ural Owl*, Latham; *Die Ural Habichtseule*, Bechstein: *Habichts-eule*, Naumann; *Uralischer und Grossköpfiger Baumkautz*, Brehm.

Geographical Distribution.—Arctic regions of the Old World, Lapland, North of Sweden, Norway and Russia. Livonia and Hungary, and Japan. Very rare in the eastern parts of Germany; very accidentally found elsewhere. Mr. Gould regards it as one of the rarest European Owls.

Habits, Food, &c.—Leverets, rats, mice, ptarmigan, and small birds. The nest is formed in the holes of trees, often near the habitations of man. Mr. Gould states that the number of eggs is two; M. Temminck says three or four. they are pure white.

Surnia Uralensis.

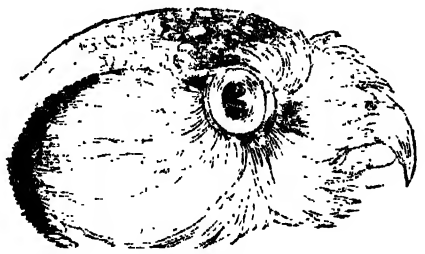
Surnia funerea.—*Description.*—*Male.*—Forehead dotted with white and brown; a black band takes its origin behind the eyes, includes the orifice of the ears as in a frame, and terminates on the sides of the neck; upper parts marked with brown and white spots of various forms; on the borders of the wings are similar white spots disposed on a brown ground; throat whitish; the other lower parts white, transversely striped with ashy brown; at the insertion of the wings a great spot of blackish brown; tail-feathers ashy brown, striped at considerable distances with transversal narrow zigzags; bill yellow varied with black spots according to age; iris bright yellow: feet feathered to the claws. Length of tail six inches and some lines. Total length upwards of fourteen inches (Temm.); Richardson says eighteen inches.

The colours of the female are less pure than those of the male, and she is rather larger.

This is the *Strix Ulula*, Linn.: *Strix funerea*, Gmel.; Forst.; *Strix Hudsonia*, Gmel.; *Strix Canadensis et Freti Hudsonis*, Briss.; *Strix Hudsonia*, Wils.: *Strix nisoria*, Meyer; *Chouette de Canada et Chouette Epervière, ou Caparacoch*, and *Chouette à longue queue de Siberie*, Buffon (*Enl.* 463, a very good figure of this species, under the erroneous name of the Ural Mountains Owl); *Chouette Epervière*, Sonn.; *Sperbereule*, Meyer: Naum.; *Habichts eule*, Bechst.; *Plattköpfige* and *Hochköpfige Habichtseule*, Brehm.; *Hawk-Owl* of Pennant and Wilson; *Little Hawk-Owl* of Edwards; *Canada Owl* of Latham. *Paypaw theecawsew*, or *Cobadecootch* of the Cree Indians; *Theechazza* of the Copper Indians and Chepewyans; and *Ood no hezoot* of the Esquimaux.

Geographical Distribution.—The Arctic Circle and Arctic regions of both continents; sometimes seen as a bird of passage in Germany, more rarely in France, but never in the southern provinces. In Britain it does not appear to have been seen; but one was taken in a collier a few miles off the coast of Cornwall in 1830.

Habits, Food, &c.—The visual organs of this species are more able to bear the light of day, at least in dull weather, and, like the Snowy Owl, it hunts frequently in the daytime. The smaller head and less perfect facial disk, combined with these habits, have obtained for it the name of *Hawk-Owl*.



Profile of Hawk-Owl.

Dr Richardson says that 'It remains all the winter in high northern latitudes, and is rarely seen so far south as Pennsylvania, and then only in severe winters. Wilson saw only two specimens in the United States. It is a common species throughout the Fur-countries from Hudson's Bay to the Pacific, and is more frequently killed than any other by the hunters, which may be partly attributed to its boldness and its habit of flying about by day. In the summer season

Hawk Owl.

it feeds principally on mice and insects; but in the snow-clad regions, which it frequents in winter, neither of these are to be procured, and it then preys mostly on ptarmigan. It is a constant attendant on the flocks of ptarmigan in their spring migrations to the northward. It builds its nest on a tree, of sticks, grass, and feathers, and lays two white eggs. When the hunters are shooting grouse, this bird is occasionally attracted by the report of the gun, and is often bold enough, on a bird being killed, to pounce down upon it, though it may be unable, from its size, to carry it off. It is also known to hover round the fires made by the natives at night.' (*Fauna Boreali-Americana.*)

Surnia nyctea.—Description.—Head small in proportion, bill black, entirely hidden by the hairy feathers at its base; plumage snow-white, but more or less variegated with transverse brown spots or stripes; the younger the bird is, the larger and more numerous are these spots and stripes. Very old individuals are pure white, without any brown spot; iris fine orange yellow; feet very well covered, so as to look almost woolly to the claws; tail rounded, not much exceeding in length the extremity of the wings. Length 24 or 25 inches. Female considerably larger than the male.

Young at the time of departure from the nest.—Covered with brown down: the first feathers bright brown.

This is the *Strix nyctea* of Forster, Latham, and Gmelin; *Strix candida* of Latham; *Strix nivea* of Daudin; *Chouette Harfang* of Buffon; *Chouette Blanche* of Le Vaillant; *Allocco Diurno* of 'Stor. degl. Ucc.;' *Schneekauz* of Bechstein; *Sneeuwuil* of Sepp; *Nordicher Schneekautz* and *Schnee Eule* of Brehm.; *Ermine Owl* and *Snowy Owl* of Latham; *Great White Owl* of Edwards; *Snow Owl* of Wilson; *Wapow Keetho* or *Wapohoo* of the Cree Indians; and *Ookpeegnak* of the Esquimaux.

Geographical Distribution.—Arctic regions of the Old and New World, Iceland, Sweden, Norway, Lapland, and the north of Europe generally. The Shetland Isles possess it, but, some think, in winter only. In the Orkneys it appears to be accidental. It has been shot in Scotland, England, and Ireland, and has been occasionally seen in Germany: in Holland a young bird was seen in the winter of 1802. It does not appear to have been seen in France. Dr. Richardson states that it frequents in summer the most arctic lands that have been visited, but retires with the ptarmigan, on which it preys, to more sheltered districts in the winter. 'Even in the latter season however,' says that author in continuation, 'it is frequently seen within the confines of the Arctic Circle; though it is not very uncommon at the same period in Canada and the northern parts of the United States; and now and then it has been known to wander as far south as Florida. . . . It hunts in the day; and indeed unless it could do so, it would be unfit to pass the summer within the Arctic Circle. When I have seen it on the barren grounds, it was generally squatting on the earth, and if put up, it alighted again after a short flight; but it was always so wary as to be approached with great difficulty. In the woody districts it shows less caution, and, according to Hearne, has been known to watch the grouse-shooters a whole day for the purpose of sharing in the spoil. On such occasions it perches on a high tree, and when a bird is shot, skims down, and carries it off before the sportsman can get near it. It preys on lemmings, hares, and birds, particularly the willow-grouse and ptarmigan. Mr. Hutchins says that it eats carrion; and Wilson informs us that it is a dexterous fisher, grasping its finny prey with an instantaneous stroke of the foot as it sails along near the surface of the water or sits on a stone in a shallow stream. I have seen it pursue an American hare on the wing, making repeated strokes at the animal with its foot; but on that occasion, through the intervention of an Indian, it ws driven from its quarry. It makes its nest on the ground, and lays three or four white eggs, of which two only are in general hatched. In winter, when this owl is fat, the Indians and white residents in the Fur-countries esteem it to be good eating. Its flesh is delicately white.' (*Fauna Boreali-Americana.*) M. Temminck states that it builds its nest on scarped rocks, or on the old pines of the glacial regions; and that it lays two eggs, marked with black spots, according to M. Vieillot, but white, according to all other naturalists. William Bullock appears to have been the first who recognised this species as a British bird during his visit to the Orkneys and Shetlands in the summer of 1812. He states that one, wounded on the Isle of Balta, disgorged a

young rabbit whole; and that one in his possession when he wrote, had in its stomach a sandpiper with its feathers entire.

N.B. The large white owl of Africa is no longer considered to be identical with this species.

Specimens in different stages of plumage are generally to be seen in the garden of the Zoological Society in the Regent's Park.

The following are also European species:—*Bubo maximus**, *Bubo Ascalaphus*, *Otus vulgaris**, *Otus brachyotos**, *Scops Aldrovandi**, *Surnia cinerea*, *Ulula nebulosa*, *Syrnium Aluco**, *Noctua nudipes** (Gould—*Strix nudipes*, Auct.), *Noctua Tengmalmi**, and *Noctua Passerina** (Gould—*Strix passerina*, Auct.).

Those marked * are in the Catalogue of British Birds. Mr. Yarrell gives *Strix passerina* and *Noctua nudipes*, Gould, as synonyms.

ASIATIC OWLS.

Example, *Strix badia*, Horsf.

Description.—General colour of the upper parts of the head, back, wings, and tail, chesnut-brown, with a bright fulvous lustre irregularly diffused over it, showing itself more strongly in particular patches; on the under parts, from the neck to the vent, the brown colour is greatly diluted, and the fulvous lustre alternates with patches of Isabella yellow. All the parts dotted with brown; ornamental collar round the neck, consisting of a compound series of delicate white plumes, terminated by a band of deep chesnut, the accidental derangements of which exhibit a beautiful alternation of the two colours: circle about the eyes and the forehead of a pale brown tint; plumes which bound the collar above and below nearly white; bill yellowish, moderate; feet thickly covered with fulvous silky plumes; toes brownish, and nearly naked, claws yellowish; quills and tail-feathers broadly banded transversely with blackish brown. Total length from the bill to the extremity of the tail, to which the wings almost reach, eleven inches; to the end of the claws, twelve inches.

This is the *Wowo-wiwi* or *Kolong-wiwi* of the Javanese.

Dr. Horsfield, from whose *Zoological Researches* the description is taken, states that this species, whose head is proportionally large, has a general resemblance to *Strix flammea* in the distribution of its colours and external marks. The upper parts are, he observes, generally dark, and the lower of a paler hue. The neck is surrounded by a loose ornamental collar; the plumes encircling the eyes are rigid, and disposed with perfect regularity, and the legs are entirely covered. A resemblance also exists, he adds, in the lustre of their covering.

Locality.—Java, in the closest forests of the district of Pugar, and the ranges of low hills south of the capital of Surakarta. (Horsf.)

Habits, Food, &c.—The habits of this species are nocturnal. Dr Horsfield, *loc. cit.*, speaking of *Strix Javanica* (which, he says, his specimens show to be merely a variety of *Strix flammea*), remarks, that it is the only species of this division which is occasionally found near villages and dwellings. 'It is not however a favourite with the natives; various superstitious notions are also in Java associated with its visits; and it is considered in many parts of the island as portending evil. The other species of this division are by no means common, and the *Strix badia* is one of those that are most rarely met with. It never visits the villages, but resides in the closest forests, which are the usual resort of the tiger. The natives even assert that the *Wowo-wiwi* approaches this animal with the same familiarity with which the Jallak (the Pastor Jalla of our catalogue) approaches the Buffalo, and that it has no dread to alight on the tiger's back.' Dr. Horsfield adds, that it is never seen in confinement.

The same author states that eight species of owls from Java have been arranged in the museum at the India House; three eared-Owls, and five smooth-headed.

AFRICAN OWLS.

Example, *Strix Capensis*, Smith.

Description.—Red brown above, scantily sprinkled with small white spots, pale ochreous red below, marked with small heart-shaped spots; face yellow-brown; cervical collar pale buff-orange, with many of the feathers, particularly of its inferior portion, tipped with brown; quills subochreous, banded with brown; eyes brownish-black; bill and feet livid or straw-yellow; legs long, upper half of the tarsi covered with feathers, lower half and toes covered with small flat circular scales, upon which are a few strong rigid bristles, claws long, dark horn-colour, slightly covered and pointed. Length 16 inches. The whole of the plumage has a silky gloss.

Female considerably larger than the male, and with the colours less clear.

Young.—Down of the nestlings dull cream-yellow, plumage of the upper parts during the first year darker than in adult birds. (Smith.)

Dr. Smith states that the few specimens which he saw were obtained near Cape Town, close to Table Mountain, in the rocky precipices of which they were said to have concealed themselves during the day. He adds, that the colonists recognise this bird as distinct from the *Doodvogel* (*Strix flammea*), which occurs abundantly throughout the whole of South Africa, and that it is at once to be distinguished by its size from *Strix badia* of Horsfield, the species to which it is by colours most nearly allied.

Dr. Smith also figures and describes another typical owl, *Athene Capensis*, described by him under the name of *Noctua Capensis*, in the *South African Quarterly Journal*, 2nd series, 1834.

The length of this species is $9\frac{1}{2}$ inches, and the bird from which the description was taken was shot in the depths of one of the forests of the eastern district of the Cape Colony. It was the second specimen of the species he had seen; the first was also killed in a forest of the same district in 1824.

The same author figures and describes in the same work (*Illustrations of the Zoology of South Africa*) an eared owl, *Otus Capensis*; total length from tip of bill to tip of tail, 15 inches: general colour, brown above, and dappled beneath on the lower parts; the female rather larger than the male, and the colours the same in both. He states that this is a rare bird in the south of Africa, and, as far as he knows, has never been found but in marshy situations. 'It passes the day among the rushes, reeds, or long grass, and five or six individuals are sometimes found congregated together. When disturbed, they fly only a short distance before they attempt to conceal themselves again, and it is not before they have been several times flushed in succession that they seek safety in a prolonged flight. They feed upon mice, lizards, and water-insects.'

AMERICAN OWLS.

Our limits will only permit us to notice, in addition to the species above recorded, which are common in Europe and America, the well-known burrowing little owl (*Noctua cunicularia*). Mr. Darwin states that this species, on the plains of Buenos Ayres, exclusively inhabits the holes of the bizcacha or viscacha [CHINCHILLIDÆ, vol. vii., p. 88]; but that in Banda Oriental it is its own workman. 'During the open day, but more especially in the evening,' says this acute observer, 'these birds may be seen in every direction, standing frequently by pairs on the hillocks, near their burrows. If disturbed, they either enter the hole, or, uttering a shrill harsh cry, move with a remarkably undulatory flight to a short distance, and then turning round, steadily gaze at their pursuer. Occasionally in the evening they may be heard hooting. I found in the stomachs of two which I opened, the remains of mice, and I one day saw a small snake killed and carried away. It is said these latter animals are their common prey during the daytime. I may here mention, as showing on what various kinds of food owls subsist, that a species that was killed among the islets of the Chonos Archipelago had its stomach full of good-sized crabs.' (*Journal of Researches in Geology and Natural History.*)

AUSTRALIAN OWLS.

Mr. Vigors and Dr. Horsfield, in their *Description of the Australian Birds in the Collection of the Linnean Society* (*Linn. Trans.*, vol. xv.), record three species of owls belonging to the genera *Noctua* and *Strix*.

Noctua.

Example, *Noctua Boobook*.

Description.—Brown above, with a few yellowish-white spots; white beneath, varied with ferruginous spots; toes hairy.

This is the *Strix Boobook*, *Boobook Owl* of Latham.

According to Mr. Caley, 'The native name of this bird is *Buck-buck*. It may be heard nearly every night during winter uttering a cry corresponding with that word. Although this cry is known to every one, yet the bird itself is known but to few; and it cost me considerable time and

trouble before I could satisfy myself respecting its identity. The note of the bird is somewhat similar to that of the European *cuckoo*, and the colonists have hence given it that name. The lower order of the settlers in New South Wales are led away by the idea that everything is the reverse in that country to what it is in England; and the *cuckoo*, as they call this bird, singing by night, is one of the instances which they point out.'

Noctua maculata, described by the same authors, much resembles the species just noticed, but they are inclined to consider it distinct.

Strix.

Example, *Strix flammea*?

Mr. Vigors and Dr. Horsfield observe that this bird varies from our European species in the buff colour being considerably darker, and the spots on the *abdomen* being larger and more deeply marked than is usual in our own. They add however that in our species there is considerable variety; and as they had an opportunity of examining a single specimen only from New Holland, and that in an inferior condition, they did not wish to state with any confidence an opinion as to the identity of these birds.

Fossil Owls.

Remains of fossil owls have been found in the gypsum of the Paris basin (first lacustrine portion of the tertiary series, Eocene of Lyell) in company with extinct species of extinct genera of *Pachydermata*, and extinct species belonging to existing genera of *Carnivora, Marsupialia, Rodentia*, and of other birds referrible to the Buzzard, Quail, Woodcock, Sea-Lark (*Tringa*), Curlew, and Pelican. Reptiles (fresh-water tortoises and crocodiles), and Fishes. Two kinds of owl belonging to existing species occur in the gypsum cavities at Köstritz, together with sheep or roe, fox, weasel, squirrel, field mouse, common rat, hamster, bat, mole, hare, rabbit, frog, domestic cock, and man (existing species), mixed confusedly with the bones of the extinct animals, rhinoceros, &c. (*Reliquiæ Diluvianæ*, p. 168.)

STRIKE, a term much employed by modern geologists, after the example of Professor Sedgwick, to denote the direction of a horizontal or level line, in the surface of inclined or vertical strata, mineral veins, dykes, &c. If the strata be vertical, their *strike* corresponds with the surface *direction* of the beds; the same happens if the strata be inclined at any angle to the horizon, provided the surface of the ground be level; but in general the outline of the edges of the strata differs from the strike. The dip, or line of greatest inclination of strata, is always at right angles to the strike, so that in conical or elliptical elevations of strata the strike is a curved line, continually varying in direction. But, generally, viewed on a large scale, irregularities of this nature vanish, and a whole great mountain-region, as North Wales, South Wales, or North Devon, manifests one predominant general strike, corresponding with one, or more than one *axis of movement*, upon which the displaced strata have been bent or broken.

STRING-COURSE, a projecting *course* of masonry forming a *string* or horizontal line on the face of a wall, and consisting of a series of mouldings, as in Gothic, or a flat surface (either plain or enriched), as in Italian architecture. In both styles, string-courses admit of great variety, and contribute very much to decoration, while they are in themselves essential members, inasmuch as they serve to define the internal division of the building, corresponding with the floors of the several stories; and by separating one tier of windows from another, to mark each as a distinct portion of the general composition, complete as regards itself, though secondary to the other. While they separate, they serve also to connect and combine the successive stages of a building; and to produce a due mixture of horizontal with perpendicular lines.

In Gothic architecture, the upper surface of a string-course is almost invariably splayed or sloped in order to shoot off rain, the projection being usually such that the wet would else lodge upon it. The string-course itself consists sometimes of only a few narrow and plain mouldings, at others of a variety of them separated by one or more considerable hollows. In the later or perpendicular style of Gothic, the string-course is frequently made a broad tablet, not only richly moulded, but ornamented with sculptured blocks, heads of animals, shields, &c. placed at intervals in the principal cavetto or hollow; besides which, additional carved ornament is occasionally introduced on the surfaces between the other mouldings. In some instances the string-course is so enlarged as to become a sort of frieze or horizontal pannel filled up with a pattern of tracery, or with lesser pannels, &c. carved on it; of which kind East Barsham Manor-house, and the parsonage at Great Snoring, afford some fine examples.

In Italian architecture, the string-course (*Fascia*, Ital.; *Cordon*, French; *Band*, German) is either quite plain, or more or less decorated according to the character of the floor to which it belongs. That which crowns a basement floor is seldom more than a *plat-band* or plain surface, while the upper ones form ornamental fascias, enriched with guilloches, frets, &c. either with or without mouldings. The Travellers' and Reform club-houses, London, are remarkable for their beauty, in regard to these members, and for the richness and finish which they contribute to the respective designs.

STROBILO'PHAGA, M. Vieillot's name for the *Corythus* of Cuvier, which has the priority. [FRINGILLIDÆ, vol. x., p. 482.]

STRO'MBIDÆ, a family of marine testaceous gastropods, belonging to the *Alata* of Lamarck and the *Angyostomata* of De Blainville.

The genus *Strombus* of Linnæus is placed in the *Systema Naturæ* between *Buccinum* and *Murex*; and is divided into the following sections:—

* *Digitati*; the lip with linear laciniæ.

Species:—*Strombi Fusus, Pes Pelecani, Chiragra, Scorpius, Lambis, Millepeda.*

** *Lobati.*

Species: —*Lentiginosus, Gallus, Auris Dianæ, Pugilis, Marginatus, Luhuanus, Gibberulus, Oniscus.*

*** *Ampliati.*

Species:—*Lucifer, Gigas, Latissimus, Epidromis, Canarium, Vittatus, Succinctus, Spinosus, Fissurella, Dentatus.*

**** *Turriti*: with a very long spire.

Species:—*Tuberculatus, Palustris, Ater,* and *Lividus.*

Lamarck's family of *Alata*, or Winged Zoophagous Trachelipods, stands between the *Canalifera* and *Purpurifera*. The *Alata* consist of the genera *Rostellaria, Pterocerus* (or, as Lamarck incorrectly writes it, *Pterocera*), and *Strombus.*

Cuvier arranges *Strombus* next to *Turbinella* and at the end of his *Pectinibranchiate Gastropods*. He defines the genus *Strombus*, Linn., as comprising shells with a canal which is either straight or inflected towards the right, the external border of whose aperture dilates with age, but always preserves a sinus towards the canal, under which the head of the animal passes when it extends itself. The greater part have, he adds, this sinus at some distance from the canal.

Cuvier nearly follows Lamarck in the subdivisions of the genus.

Of the *Strombi*, properly so called, he says, that the external border or lip dilates into a wing, which is more or less extended, but not divided into digits. Their foot is small in proportion, and their tentacles carry their eyes on a lateral pedicle, stouter than the tentacle itself. The *operculum* is horny, long, and narrow, carried on a slender tail.

The *Pterocerata* he characterises as having the external lip divided in the adult into long and slender digitations, varying in number according to the species. The animal is the same as in the *Strombi* properly so called.

The *Rostellariæ*, he remarks, have, in general, a second canal reascending along the spire and formed by the external lip and by a continuation of the columella. In some the lip is still digitated. Their animal resembles that of *Murex*, but carries only a very small operculum (*Strombus Pes Pelecani—Rostellaria Pes Pelecani*, Lam.; *Aporrhais*, Petiv.). Others again have no more than dentilations on the edge of the lip (*Strombus Fusus*); and others have the lip entire (*Hippochrenes*, Montf.).

Mr. Swainson defines the *Strombidæ*, *Wing-Shells*, which, in his arrangement, stand between the *Turbinellidæ* and the *Volutidæ*, thus:—

'Outer lip dilated, or thickened internally, or detached from the preceding whorl by a sinus; operculum small.'

He makes the family consist of the following subfamilies:—

1. *Strombinæ.*

Subfam. Character.—Outer lip considerably dilated, but never toothed; spire rarely longer than the aperture; with a sinus near the base.

Genera:—*Aphorrais*, Da Costa (*Aporrhais*, we suppose,

is meant); *Pteroceras*, Lam.; *Strombus*, Linn.; *Strombidea*, Sw.; *Rostellaria*, Lam.

2. *Coninæ.*

Subfam. Character.—Shell coniform; the spire very short, pyramidical or truncate; outer lip slightly detached above, but without a basal sinus.

Genera:—*Terebellum*, Lam.; *Coronaxis*, Sw. (with the subgenera, *Coronaxis*, Sw.; *Puncticulis?* Sw.; *Tuliparia*, Sw.; *Cylindrella*, Sw.; and *Conilithes*, Sw.); *Conus*, Linn. (with the subgenera *Conus*, Linn.; *Dendroconus*, Sw.; *Textilia*, Sw.; *Theliconus*, Sw.; and *Leptoconus*, Sw.); *Conella*, Sw.; and *Conorbis*, Sw.

3. *Columbellinæ.*

Subfam. Character.—Shell small; outer lip considerably thickened within, where the margin is invariably either toothed or striated; the top gibbous, the margin generally inflexed; inner lip doubly toothed, *i.e.* internally and externally; aperture narrow, generally ringent; operculum minute.

Genera:—*Conidea*, Sw.; *Columbella*, Lam.; *Pusiostoma*, Sw.; *Crassispira*, Sw.; *Nitidella*, Sw.

4. *Pleurotominæ.*

Subfam. Character.—Shell turreted, subfusiform; the base channelled, and often much produced; outer lip never thickened, but detached at the top from the whorl by a slit or sinus.

Genera:—*Brachytoma*, Sw.; *Pleurotoma*, Lam.; *Clavatula*, Sw.; *Clavicantha*, Sw.; *Tomella*, Sw.

5. *Cerithinæ.*

Subfam. Character.—Shell clavate, generally mucronate; the spire very long; the outer lip considerably dilated; the base either truncate or forming a short recurved channel.

Genera:—*Potomis*, Brong.; *Pirena*, Lam.; *Terebralia*, Sw.; *Rhinoclavis*, Sw.; *Cerithium*, Lam.

Mr. J. E. Gray makes the *Strombidæ* (the first family of his section *Ctenobranchiata*, Order 1, *Zoophaga*) include the following genera: *Strombus*, *Terebellum*, *Pteroceras*, *Rostellaria*, and *Seraphys*.

In this article the *Strombidæ* will be confined to the genera and subgenera *Strombus*, *Pteroceras*, and *Rostellaria*.

Strombus.

Generic Character.—*Animal* spiral, slightly compressed, furnished with a *proboscis*, at the extremity of which is the mouth opening longitudinally, and containing a lingual riband furnished with sharp points curved backwards: *tentacles* cylindrical, obtuse, and short: *eyes* carried upon two peduncles, which are cylindrical and stout, longer than the tentacles and placed at their external side; *foot* rather small, but enlarged forwards; *mantle* forming in front a canal, which is generally rather short; orifices of the anus and oviduct behind.

Shell thick, oval, oblong, subinvolved, conical in front and behind; spire moderately elevated; aperture long and narrow, terminated anteriorly by a canal more or less long or removed; right lip dilated, and with a sinus a little behind the canal; columellar or inner lip simple, but sometimes callous.

Operculum horny, long and narrow, with a terminal summit, and composed of elements imbricated, as it were. (Rang.)

M. Rang considers that the variations in the shell lead to the establishment of two subgenera, *Strombus* and *Pteroceras*.

M. de Blainville divides the genus *Strombus* into the following sections:—

α. Species whose external lip becomes much dilated with age, and offers a number of digitations variable in number. (Genus *Pteroceras*, Lam.)

Example, *Strombus Scorpius.*

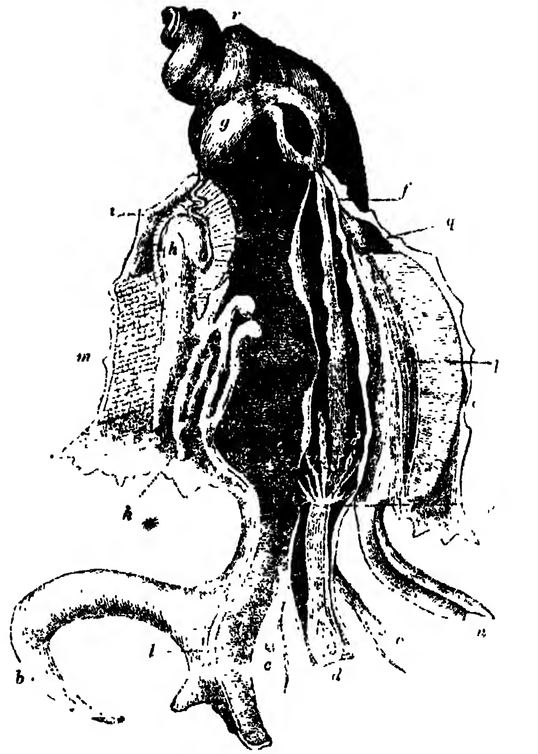
β. Species whose right lip is much dilated, but without digitation.

Example, *Strombus tricornis.*

γ. Species whose external lip is thick, and but little or not at all dilated.

Example, *Strombus Auris Dianæ.*

δ. Species whose right lip is not dilated, and very delicate, which makes them resemble the Cones. (Non-adult Strombi.)



Animal of Strombus lambis; *Pteroceras lambis* of modern authors. (female.)

a, the foot seen in its anterior part with its groove; *b*, the operculum fixed at its posterior division; *c*, *c*, ocular tubes with their tentacles; *d*, the proboscis open to show the tongue; *e*, the cerebral ganglion, behind which are two long salivary glands; *f*, digestive tube entering a large stomach; *g*, the stomach partially opened, and showing the orifice of the œsophagus; *h*, the intestine forming a fold before it forms the very voluminous rectum; *i*, the first part of the uterus; *k*, second part of the uterus, forming meanders before opening into the groove which leads on the right side of the foot; *l*, the groove which does not exist in the males; *m*, follicles of viscosity; *n*, respiratory siphon; *o*, large branchia and its vein which goes to the heart; *p*, small and rudimentary branchia; *q*, the heart; *r*, the liver and the ovary united to the extremity of the tortillon, or turbinated part of the body. (*Voyage of the Astrolabe.*)

Subgenus Strombus.

See the generic character above given for the *animal*.

Shell with a simple wing, and a very short canal, which is truncated or notched.

Operculum.—See the generic character above stated.

The species are extremely numerous, and many of them are gigantic in size, the well-known *Strombus Gigas* of the West Indies for example. Like some others of the turbinated testaceans, the animals of the genus Strombus occasionally produce pearls. Mr. Wood, in his 'Zoography,' relates that he saw a pink pearl which was taken from the body of the animal of *Strombus Gigas*, which is fished for the table off the island of Barbadoes. The pearl was discovered by chance, while the men were employed in cleaning the fish. Its weight was 24 grains, but it would have been more valuable if it had been round. The same author states that only four of these pearls had been discovered in the vast numbers of shell fish that are annually brought to market in that part of the world, though he has reason to believe that this is in some measure owing to the carelessness of the negroes, who clean their fish without consideration, and have probably in their hurry returned many a pearl to its native element with the refuse of the animal. This pearl was exactly of the same colour as the interior coat of the shell, and like it in every respect except in figure.

Geographical Distribution of the Genus, Habits, &c.—The seas of warm climates; many from those of India, and some from those under and near the equator. Carnivorous. Species have been found at depths varying from 0 to 13 fathoms.

M. Deshayes, in his Tables, makes the number of recent *Strombi* forty-five. M. de Blainville reckons them at fifty-two; of these *Strombus Gigas* is noted as found both recent and fossil (tertiary).

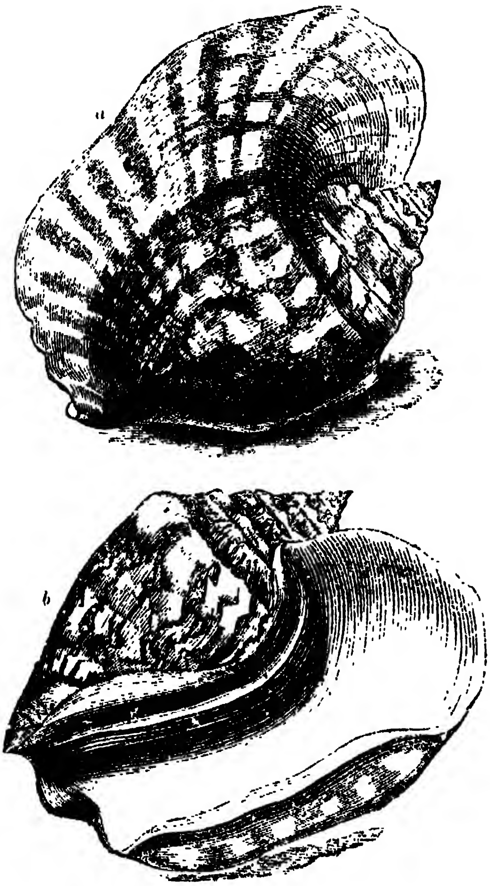
Example, *Strombus latissimus.*

Description.—Shell turbinated, ventricose, smooth on the

back, somewhat wrinkled on the wing, brown orange spotted with white; the spire short and nodulous: the external lip very broad, rounded above, projecting beyond the spire, the anterior margin sharp, but the side of it very thick; the aperture smooth and white, tinged with rose colour.

Locality.—East Indian Seas.

This fine and somewhat rare species grows to a large size, from five to ten or more inches in length.



Strombus latissimus.
a, seen from above; *b*, seen from below

We have selected this species because it is one of those that leads to the next subgenus.

Pteroceras.

Animal.—See the generic character above stated, and the cut and description of the animal, p. 123.

Shell with the wing digitated, and furnished forwards with an elongated canal.

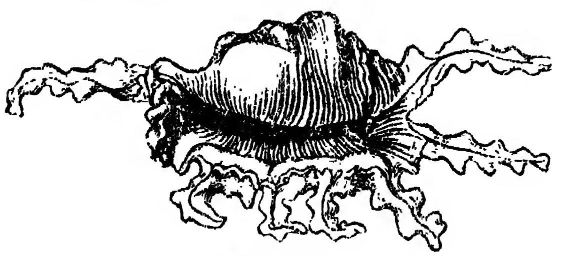
Operculum.—See the generic character above.

Geographical Distribution of the Genus, Habits, &c. The Indian seas. Carnivorous. *Pterocerata* have as yet been only noticed as littoral.

The *Pterocerata* are very much less numerous than the *Strombi*. M. Deshayes, in his Tables, makes their number seven: no fossils.

Example, *Pteroceras Scorpius.*

Description.—*Shell* ovate-oblong, gibbous, tuberculate; transversely rugose and knotty, seven fingered, white



Pteroceras Scorpius.

spotted with rufous, the fingers rather slender, and knotted at intervals throughout their length, the anterior ones and the tail the longest, and curved; aperture violaceous-red wrinkled with white.

Locality.—East Indian Seas.

Rostellaria.

This genus is placed between *Pleurotoma* and *Fusus* among his SIPHONOSTOMATA by M. de Blainville. M. Rang arranges it between *Pleurotoma* and *Strombus*. Cuvier places it under the latter genus.

Generic Character.—*Animal* imperfectly known, but bearing a considerable resemblance to that of *Murex*, according to Cuvier.

Shell fusiform or subturriculate, with an elevated pointed spire; aperture oval, canal projecting, and terminating in a pointed beak; external lip simple, dentated, digitated, or very much dilated, furnished with a sinus near the canal, and having generally a second canal ascending upon part of the spire.

Geographical Distribution of the Genus, Habits, &c.—The Asiatic Seas, if we except *Rostellariæ Pes Pelecani* and *Pes Carbonis* (genus *Aporrhais*), which are found in the Mediterranean and other European seas. A very fine specimen of *Rostellaria rectirostris* was brought up in the mud lying on the fluke of an Indiaman's anchor, in the Straits of Macassar. Carnivorous.

The number of recent species enumerated by M. Deshayes in his Tables is seven recent, and, of these, three, *Rostellariæ Pes Pelecani*, *Pes Carbonis*, and a new species, are noted as being found both living and fossil (tertiary).

M. de Blainville thus divides the genus:—

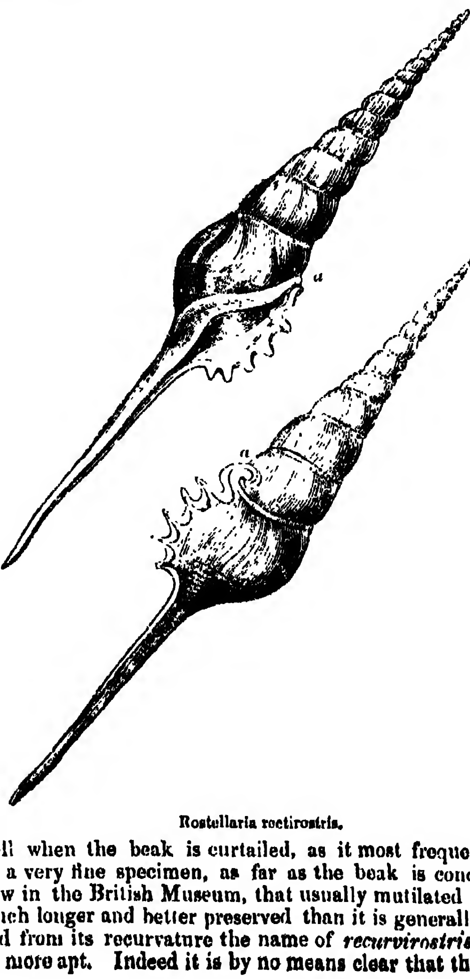
α Species whose external lip is digitated.

Example, *Rostellaria curvirostris.*

β. Species whose external lip is dilated and not dentated.

Example, *Rostellaria Macroptera* (genus *Hippochrenes* of De Montfort—fossil).

Rostellaria curvirostris (*Strombus fusus*, Linn.), the *Spindle* of collectors, is by far the most common of the Asiatic species. We illustrate the genus by *Rostellaria rectirostris*, Lam., a name which suits this rare species



Rostellaria rectirostris.

well when the beak is curtailed, as it most frequently is. In a very fine specimen, as far as the beak is concerned, now in the British Museum, that usually mutilated part is much longer and better preserved than it is generally seen, and from its recurvature the name of *recurvirostris* would be more apt. Indeed it is by no means clear that there are

not two species of this long-beaked kind of *Rostellaria*, one much darker than the other, and not so slender.

Description.—Shell fusiform-turreted, smooth in the middle, squalid white; the whorls rather convex, the last transversely sulcated below, the upper more convex and cancellated; external lip toothed on the margin; beak very long, slender, very straight.

Such is Lamarck's description; but those unfaded specimens which we have seen have been of different hues of brown. The lip terminates above in an elegantly turned canal or volute upon the bottom whorl of the spire, *a a* in the subjoined cut. Some specimens that we have seen have been of a deep brown, approaching to black in the inside of the outer lip. In the young shells the external lip is not dentated. Lamarck gives the length of the adult as 5 inches 10 lines, but the shell above noticed as being in the British Museum, and which has the longest beak we ever saw in the species, is of much greater length. The shell is called by collectors the *Chinese Spindle.*

FOSSIL STROMBIDÆ.

Strombus.

Lamarck records but one fossil species, *Str. Canalis* (Grignon). M. de Blainville remarks that when he wrote (1825) only five species of true *Strombi* had been found fossil, one of which, from the Plaisantin, is an analogue, according to Brocchi.

M. Deshayes, in his Tables, makes the number of fossil *Strombi* (tertiary) nine, *Str. Gigas* being, as already stated, both recent and fossil.

Rostellaria.

Lamarck records the following fossil species:—*Rostellaria macroptera* (*Strombus amplus*, Brand; *Hippochrenes macropterus*, Montf.), from St. Germain-en-Laye; *Rostellaria columbata*, from the same locality, and *Rostellaria fissurella*, from Grignon and Courtagnon.

Defrance notices fifteen fossil species; one identical from the Plaisantin, and an analogue from Grignon.

M Deshayes, in his Tables, records the number of fossil (tertiary) *Rostellariæ* as eight; three species, as above stated, being both recent and fossil.

Mr. Lea (*Contributions to Geology*) describes and names two species, *Rostellaria Lamarckii* and *Cuvieri*, from the Claiborne Beds, Alabama (tertiary).

Dr. Mantell (*Organic Remains of the County of Sussex*) records *Rostellaria Sowerbii* from the arenaceous limestone or sandstone of Bognor; and *Rostellariæ Parkinsoni*, *carinata*, and a species 'with two processes' very closely resembling *R. Pes. Pelecani* (genus *Aporrhais* of some authors), from the Shanklin sand.

Professor Phillips (*Organic Remains of the Yorkshire Coast*) notes *Rostellariæ Parkinsoni* from the Speeton Clay; *composita*, from the Bath and inferior oolite; *bispinosa* from the calc. grit and Kelloways rock; and *trifida* from the Oxford clay.

Professor Sedgwick and Mr. Murchison (*Structure of the Eastern Alps*) record *Rostellariæ costata*, *granulata*, and *lævigata* from the Gosau deposit and its equivalents in the Alps.

Dr. Fitton (*Strata below the Chalk*) gives the following species in his well digested Stratigraphical and Local table: *Rostellariæ buccinoides*, from the gault, Kent; *calcarata* from the gault, Kent, the lower green-sand of Sussex, Isle of Wight, and Norfolk, and from Blackdown; *carinata*, from the gault of Kent, Surrey, and South Wilts; *elongata*, from the gault of Kent; *marginata* from the same locality; *macrostoma* from Blackdown; *Parkinsonii*, from the gault of Kent, the lower green-sand of Sussex and the Isle of Wight, and from Blackdown; *retusa* from Blackdown; *doubtful* from the lower green-sand of Kent; very like *Pes Pelecani* from the lower green-sand of Sussex; and a new species from Blackdown.

STROMNITE. [STRONTIUM.]

STRONSA. [ORKNEY ISLANDS.]

STRÖNSTED. [SWEDEN.]

STRO'NTIUM, a peculiar metal found in combination with oxygen and carbonic or sulphuric acid, and forming the carbonate and sulphate of strontia. From the very considerable resemblance existing between barytes and strontia they were once supposed to be identical. Crawford and Sulze noticed a difference between them, and in the year 1792 Dr. Hope established sufficient differences to prove that they were completely distinct bodies, and the newly discovered body was named *Strontia* or *Strontites*, from Strontian in Scotland, the place in which it was discovered.

Strontium was procured from the carbonate of strontia by Davy in 1808; the method adopted is that which we have described for obtaining barium [BARIUM] from the carbonate of barytes. Its properties have been but imperfectly examined; it has not a very high lustre, is heavier than sulphuric acid, appeared fixed, difficultly fusible, and not volatile. When exposed to the air it attracted oxygen, and became converted into strontia; when thrown into water, it decomposes it with great violence, producing hydrogen gas, and forming with the water a solution of strontia.

Oxygen and Strontium, as just mentioned, readily unite, constituting the *protoxide*, or *strontia*, which exists largely in nature, and the *peroxide*, which is entirely an artificial product. The simplest mode of procuring the protoxide, or strontia, when required to be free from water, is to dissolve the native carbonate in nitric acid, and to decompose the crystallized nitrate obtained at a red heat; or the sulphate of strontia, which is a much more common substance, may be converted by the well known means first into sulphuret and then into nitrate. The properties of strontia are, that it has a greyish-white colour; its specific gravity is between 3 and 4; it is very infusible, not volatile, has an acrid taste, and has an alkaline reaction on vegetable colours. On comparing these properties with those of barytes, it will be observed that there is considerable resemblance between them, but they differ in one remarkable respect, namely, that strontia, unlike barytes, is not poisonous. When exposed to the air it attracts carbonic acid, and is reconverted to the state of carbonate.

Strontia is composed of—

One equivalent of oxygen . .	8
One equivalent of strontium . .	44
Equivalent . . .	52

Strontia and Water combine to form at least two compounds: when a small quantity of water is poured upon strontia, it slacks, gives out heat, is rendered white; and becoming a hydrate, it is fusible at a white heat, but does not part with its water.

It consists of—

One equivalent of water . .	9
One equivalent of strontia . .	52
Equivalent . . .	61

According to Davy, strontia is soluble in about two hundred times its weight of water at common temperatures. The solution is called *Strontia water*, and is occasionally employed as a chemical reagent; it acts energetically as an alkali on vegetable colours and in saturating acids. In boiling water strontia is much more soluble than in cold. As the solution cools, crystals, the primary form of which is a right square prism, are deposited, and these appear to consist of—

Ten equivalents of water . .	90
One equivalent of strontia . .	52
Equivalent . . .	142

Peroxide of Strontium may probably be obtained, as the peroxide of barium is, by passing oxygen gas over strontia at a red heat, or by heating it with chlorate of potash. It appears to contain two equivalents of oxygen to one of strontia, but is not an important compound.

Neither azote nor hydrogen unites with strontium.

Chlorine and Strontium combine to form only one compound, consisting of—

One equivalent of chlorine . .	36
One equivalent of strontium . .	44
Equivalent . . .	80

The best mode of procuring this salt is to dissolve carbonate of strontia in dilute hydrochloric acid, and to evaporate the solution to its crystallizing point, the chloride containing water then separates in long slender crystals, which consist of 1 equivalent of chloride 80 + 1 equivalent of water 9. When exposed to heat the water is expelled, and a solid white chloride remains. The crystals deliquesce in a moist atmosphere, are soluble in twice their weight of

water at 60°, and still more so in boiling water; this salt is soluble also in alcohol, and the solution when burning exhibits the peculiar red flame characteristic of the compounds of this base.

Chloride of strontium may be more directly, but less eligibly, prepared than in the mode now described, by passing chlorine gas over heated strontia; oxygen gas is expelled, and chloride of strontium remains.

Fluoride of Strontium is an insoluble pulverulent compound.

Sulphuret of Strontium may be formed either by heating the native sulphate with charcoal, or by fusing strontia and sulphur in a green glass tube. It dissolves in hot water, and as the solution cools crystals of sulphuret of strontium are formed. They appear to contain water, independently of which they are probably composed of—

One equivalent of sulphur	16
One equivalent of strontium	44
Equivalent	60

This compound is used for the preparation of the salts of strontia, the sulphate being a much more common substance than the carbonate, which is preferable however when obtainable.

We shall now describe three oxisalts of strontia, two of which exist in nature, and the third is occasionally employed in chemical researches.

Carbonate of Strontia: Strontianite.—This was the first discovered compound of strontia; it occurs crystallized and massive. Primary form a right rhombic prism. Cleavage parallel to the lateral faces of the primary form. Fracture uneven. Hardness, scratches carbonate of lime, but is scratched by fluor-spar. Colour white, greenish, greyish, and brown. Streak white. Lustre vitreous. Transparent, translucent. Specific gravity 3·605.

Before the blow-pipe it fuses, and gives a purple light. Dissolves with effervescence in dilute nitric acid, and the solution is precipitated by sulphuric acid.

Massive Varieties.—Amorphous, globular. Structure fibrous, sometimes granular.

Found at Strontian in Scotland, Braunsdorf in Saxony, and in Peru.

Analysis by Klaproth:—

Carbonic acid	30·
Strontia	69·5
Water	0·5
	100·

Stromnite, or *Barystrontianite*, or *Barytiferous Carbonate of Strontia*, is a mineral found at Stromness in Orkney. It occurs massive. Structure fibrous. Hardness 3·5. Specific gravity 3·7. Lustre somewhat pearly. Translucent on the edges. Colour greyish and yellowish white. It is soft and brittle. Effervesces with acids, but does not melt before the blow-pipe.

According to Dr. Traill, who discovered this substance, it consists of—

Carbonate of strontia	68·6
Sulphate of barytes	27·5
Carbonate of lime	2·6
Oxide of iron	0·1
Loss	1·2
	100·

Carbonate of Strontia may be artificially obtained by several processes; as by exposing strontia water to the air, or by adding an alkaline carbonate to it; or by decomposing any soluble salt of strontia, by means of an alkaline carbonate, &c. In whatever mode obtained, it is a colourless insipid powder, quite insoluble in water, decomposed by acids with effervescence, and by exposure to a high temperature. It is used for preparing the various salts of strontia, and is composed of—

One equivalent of carbonic acid	22
One equivalent of strontia	52
Equivalent	74

Sulphate of Strontia: Celestin.—Exists largely in nature. It occurs crystallized and massive. Primary form a right rhombic prism. Cleavage easy, parallel to the base of the primary form, but less so in the direction of the lateral faces. Fracture conchoidal, uneven. Scratches carbonate of lime, but it is scratched by fluor-spar. It is brittle. Colour white, bluish, reddish-white. Transparent; translucent. Lustre vitreous. Specific gravity 3·858.

The *Massive Varieties* are nodular, tabular, and amorphous. Structure columnar, fibrous, granular.

It is not acted upon by acids. Before the blow-pipe it decrepitates and fuses into a white friable enamel. The powder becomes phosphorescent on a hot iron.

According to Klaproth it consists of—

Sulphuric acid	42
Strontia	58
	100

This substance occurs near Bristol, in Sicily, at Bex in Switzerland, &c.

Sulphate of Strontia and Barytes: Grunerite.—This mineral is found in Hanover. It occurs massive. Its structure is radiated. Hardness 3·0 to 3·5. Colour white, with sometimes a shade of blue. Translucent. Lustre vitreous. Specific gravity 3·76.

Sulphate of Strontia may be obtained artificially, by adding sulphuric acid, or a sulphate, to any soluble salt of strontia. It is a colourless, insipid, heavy powder, insoluble in water, and dissolved only by strong sulphuric acid, from which it is precipitated by water. It is composed of—

One equivalent of sulphuric acid	40
One equivalent of strontia	52
Equivalent	92

Nitrate of Strontia is procured by dissolving the carbonate in dilute nitric acid, or by decomposing the sulphuret of strontium with it. The solution is colourless, and by evaporation yields crystals, which are composed of—

One equivalent of nitric acid	54
One equivalent of strontia	52
Equivalent	106

It crystallizes in octohedrons, is soluble in five parts of water at 60°, and in half a part at 212°. It is insoluble in alcohol, but when finely powdered and mixed with it, the alcohol burns with a beautiful red flame.

Under peculiar circumstances a hydrate nitrate of strontia is formed, containing four equivalents of water. The form of this is an oblique rhombic prism.

The salts of strontia are occasionally used in chemical investigations, and in giving a purple flame to fire-works.

STROPHE (στροφή) is a set of verses composed according to a certain system of metres. The word is derived from στρέφω, 'to turn,' as in the lyric, especially the choral poetry of the Greeks, this part of a poem was sung during the movements and dances of the chorus. In modern times such a combination of verses, written either in the same or in different metres, is commonly designated by the Italian name stanza. The division of a poem into strophes was however applied by the antients only to lyric poetry, and here one strophe seldom exceeded the number of four verses, with the exception of the dramatic and other choruses, in which a strophe sometimes contains a considerable number of verses. However different the metre of the several verses may be, there is always a unity of rhythm in them which characterises a strophe as an artistic whole. The various kinds of strophes were designated by the antients by various names which either indicated the number of verses they contained, such as disticha, tristicha, tetrasticha, &c., or were derived from the name of their inventors, or from the characteristic metre in which they were composed, such as the Alcaic, Sapphic, Choriambic strophe, &c. Again, strophes in which all the verses are of the same metre are called monocola, and those consisting of verses of two, three, or four different metres, are called dicola, tricola, or tetracola. The choral poems of the Greeks generally consisted of three main parts, strophe, antistrophe, and epode. The antistrophe always corresponds in its metre with the strophe, and thus forms a second stanza, equal to the first; the epode differs from both, and forms the concluding stanza of a chorus. (G. Hermann, *Elementa Doctr. Metr.*, p. 433, ed. Glasgow.)

STROPHO'MENA, M. Rafinesque's name for the brachiopodous fossil shell described by Dalman under the name of *Orthis*. [BRACHIOPODA, vol. v., p. 313.]

STROPHO'STOMA, the name given by M. Deshayes to a fossil shell somewhat resembling *Anostoma*, with the aperture reflected towards the spire. [HELICIDÆ, vol. xii., p. 110.]

STRO'PHULUS is an eruption of pimples upon the skin, which frequently occurs in infants whose health is disordered by the irritation of teething or any other cause. Dr. Willan describes the following forms of the disease:—

1. S. intertinctus, of which the vulgar name is red-gum or red-gown. The eruption in this form consists of vivid-red distinct papulæ, scattered in varying numbers over the cheeks, the arms, the backs of the hands, or, in some cases, the whole body. After an uncertain duration the papulæ disappear, the cuticle separating in scurf; but very frequently the fading of one eruption is rapidly followed by the appearance of another, which passes through similar stages, and generally spreads further over the skin. A few of the papulæ in each eruption sometimes assume the character of small pustules, a little fluid being formed in their apices: but this commonly disappears without bursting. The origin of the eruption may usually be traced to disorder of the digestive organs, by a gentle correction of which it may be cured. A sudden repulsion of it by exposure to the cold, or any injudicious remedies, may bring on diarrhœa, and even severe general illness. In itself it is a disease of no importance.

2. S. albidus differs from the preceding only in the colour of the papulæ, which consist of minute whitish specks, slightly elevated, and usually surrounded by a pale ring of red. They appear in the same situations as those of the first variety, are referrible to a similar origin, and require no other treatment.

3. S. confertus is often called the tooth-rash, and the rank red-gum. It occurs only during the process of teething, and consists (in children of three or four months old) of small closely-set papulæ, less vivid but more permanent than those in S. intertinctus. Their usual seat is on the cheeks and sides of the nose; sometimes they extend to the forehead and the arms, and sometimes large papulæ appear upon the loins. If the eruption occurs when the infant is eight or nine months old, it generally assumes a severer form: one or two extensive patches appear on the arms, shoulder, or neck, the papulæ in each being hard, large, and set so closely, that the whole surface of the skin seems bright red. These usually continue for a fortnight, spreading slowly from one part to another, and then fade, leaving the part, after the exfoliation of the cuticle, rough and discoloured for a week or two longer. A similar, but more obstinate and painful form of eruption, sometimes appears on the lower extremities and the lower part of the trunk. It is never advisable however to adopt any active treatment for the remedy of this variety of the disease. It commonly continues during the whole of the early period of dentition; but it affords in some measure a safeguard against more serious disorders, and disappears soon after the first teeth have cut through the gums.

4. The S. volaticus is characterised by small circular clusters of from six to twelve bright-red papulæ, which break out successively in many different parts of the body, remaining in each for about four days, and then becoming brown and disappearing with scurf. The complaint generally lasts three or four weeks, and passes in successive eruptions over a considerable part of the body. It is attended by slight fever and general disturbance of the system, and is most common in children of from three to six months old.

5. S. candidus is distinguished by the papulæ being larger than in any other variety. Their surfaces are smooth and shining, and, their bases not being inflamed, they seem paler than the adjoining skin: they usually last for about a week, and disappear in the same manner as those in the preceding forms. An eruption of this kind is most common in children a year old, who have shortly before its appearance suffered from some acute disease. It requires no active treatment: like all the other varieties of the disorder, it ceases with the irritation from which it has its origin.

STROUD, a parliamentary borough in Gloucestershire. It includes an extensive district, comprehending the parishes of Stroud, Bisley, Painswick, Pitchcomb, Randwick, Stonehouse, Leonard Stanley (excepting a detached portion called Lorridge's farm), King's Stanley, Rodborough, Minchinhampton, Woodchester, Avening, and Horsley; and extending into the four hundreds of Bisley, Dudstone and King's Barton, Longtrees, and Whitstone; its greatest length is about 10 miles from north to south, and nearly the same distance from east and west; its area and population, according to the returns of 1831, were as follows:—

	Area.	Houses.			Population.	
Bisley Hundred.	Acres.	Inhab.	Uninhab.	Building.	Families.	Persons
Stroud .	3990	1746	165	33	1859	8607
Bisley .	7980	1264	116	3	1264	[illegible]
Painswick	6510	837	118	..	886	4099
Dudstone and King's Barton Hundred.						
Pitchcomb	500	43	4	..	43	224
Longtrees Hundred.						
Avening	4660	500	45	3	507	2396
Minchinhampton	4880	1116	153	..	1131	5114
Rodborough	1390	431	67	1	436	2141
Woodchester . .	1180	187	23	1	189	885
Horsley .	4480	799	125	13	836	3690
Whitstone Hundred.						
King's Stanley . .	1740	464	55	2	514	2138
Leonard Stanley	910	184	12	..	184	942
Stonehouse	2260	516	17	8	551	2169
Randwick	1260	203	29	..	215	1031
Total .	41,740	8290	929	64	8618	39,932

From this is to be taken the detached portion of the parish of Leonard Stanley, which is excluded from the borough, but is not distinguished from the rest of the parish in the Population Returns. It has an area of about 300 acres. In the Report of the Parliamentary Boundary Commissioners, it was proposed to include the parish of Eastington, but the Boundary Act did not include it. It adjoins the eastern extremity of the borough.

The borough of Stroud comprehends an important part of the west of England clothing district, drained by the branches of the Stroudwater, which joins the Severn between Gloucester and Berkeley; 'the peculiar features of the district are, the situation of the mills on streams in deep ravines; the scattered and irregular manner in which the houses are built on the hill sides; and the contrast between the high land (in many cases either wood or common, with few inhabitants) and the valleys studded with houses and thickly peopled.' (*Boundary Commissioners' Report.*) It comprehends the market-towns of Stroud, Minchinhampton, and Painswick. Stroud, which gives name to the borough, is 111 miles west by north of the General Post-office, London, viz. 81 miles by the Great Western Railway to Swindon, 18 miles by branch to Cirencester, and 12 miles from Cirencester to Stroud by coach road; the distance by the coach road through Maidenhead, Henley, Abingdon, Faringdon, Lechlade, and Cirencester is 105 miles. Stroud is 9½ miles south of Gloucester. Minchinhampton is 4 miles south-east of Stroud; and Painswick about the same distance north, on the road to Gloucester.

Stroud stands in a picturesque valley at the junction of two of the streams which form the Stroudwater (sometimes called the Frome), a stream celebrated as possessing superior excellence for the dyeing of scarlet cloth. This quality led to this district being early chosen by clothiers and dyers. The town has been greatly improved in modern times; the streets are paved, and contain many good houses. The church is a large building of various dates; it consists of a nave, chancel, and side aisles, with a tower and spire at the western end. A new church has lately been erected in the parish capable of accommodating 1000 persons; and there are places of worship for Baptists, Independents, and Wesleyan Methodists. The market, which is on Friday, is well supplied, and there are two yearly cattle-fairs. It is one of the polling-places for the eastern division of the county. Petty-sessions for the division are held here. The living of Stroud is a perpetual curacy, of the clear yearly value of 132*l.*

Minchinhampton and Painswick, as well as the village of Bisley, are described elsewhere. [GLOUCESTERSHIRE.]

Rodborough is a village one mile south-west of Stroud. The church, formerly a chapel to Minchinhampton, 'has a tower with pinnacles; and a nave, chancel, and south transept: amidst many alterations, some antient features remain. (Rickman.) The Independents have a place of worship. Nailsworth is a chapelry, partly in Avening and partly in Horsley parish. The village of Nailsworth is about

two miles south-west of Minchinhampton, and extends into Minchinhampton parish. It has several dissenting meeting-houses. A customary market is held on Saturday. Horsley is about two miles south-south-west of Nailsworth, and six south of Stroud. It has a church and two dissenting meeting-houses, a national school, and a small house of correction. Petty-sessions for the district of Longtree are held in turn at Horsley, Rodborough, and Tetbury, the last being out of the borough. King's Stanley, three miles south-west of Stroud, has some antiquities, as the remains of a Roman camp, and of a residence of the Mercian kings. Several Roman altars and other antiquities were dug up about two miles from the camp. Leonard (or St. Leonard) Stanley, four miles west-south-west of Stroud, has some remains of a priory of Benedictines, dedicated to St. Leonard. The conventual church, now parochial, is partly of early English architecture. The convent kitchen is used as a dairy. Leonard Stanley was formerly a market-town; it is now a scattered and irregular village, but has a considerable share in the clothing manufacture. Stonehouse, four miles west of Stroud, has an antient church which retains many of its antient features, though much modernised: the north door is Norman. Woodchester, two miles south-west of Stroud, was probably a Roman station. Interesting remains of a Roman villa have been discovered here, especially a large tessellated pavement, 48 feet 10 inches square, very richly and elaborately ornamented, and far superior to anything of the kind discovered in Great Britain.

The number of persons engaged in manufactures, almost entirely of woollen cloth, in 1831, was 2539. The Stroud canal, or Stroudwater navigation, passes through the borough. It commences in the Severn near Framiload, between Gloucester and Berkeley, and runs eastward eight miles to Wallbridge, near Stroud, where it joins the Thames and Severn Canal, which runs by Stroud, 30 miles eastward to the Thames at Lechlade. The Stroudwater navigation was formed under acts passed between 1730 and 1776; the Thames and Severn Canal under acts passed from 1783 to 1813.

All the parishes in the borough are in the archdeaconry of Gloucester and diocese of Gloucester and Bristol; and all, we believe, except Pitchcomb, in the rural deanery of Stonehouse: Pitchcomb is in the deanery of Gloucester.

The parishes comprehended in the borough (including the detached part of Leonard Stanley, which we have no means of distinguishing) had, in 1833, eighty-seven day-schools of all kinds, with 3245 scholars, viz. 1304 boys, 970 girls, and 971 children of sex not distinguished: six of these day-schools were also Sunday-schools, and were attended on Sunday by 480 children. There were forty-four Sunday-schools, beside the six just mentioned, with 6132 scholars of both sexes.

The borough returns two members to parliament: the number of electors on the register in 1835-6 was 1295; in 1839-40 it was 1202. (*Parliamentary Papers.*)

STROUD. [ROCHESTER.]

STROZZI, an historical family of Florence, of the period of the republic, which produced many distinguished men both in learning and politics. The Strozzi are mentioned in the beginning of the fourteenth century by the chronicler Dino Compagni as belonging to the Guelph and Neri party, of which they became one of the leading families. After the revolt of the lower orders, in 1378, was suppressed, Tommaso Strozzi joined Salvestro de' Medici, Benedetto Alberti, and Giorgio Scali, in supporting the popular government against the burgher aristocracy, at the head of which were the Albizzi and some of the Strozzi themselves, who, on suspicion of a conspiracy against the existing government, were seized in 1379, and summarily put to death. A fresh insurrection, in 1381, upset both Tommaso Strozzi and Giorgio Scali: Strozzi escaped, but Scali was beheaded. Tommaso Strozzi retired to Mantua, whither a branch of the Strozzi was thus transplanted.

In the following century the most conspicuous of the family was Palla Strozzi, who filled several high offices: he was at the siege and surrender of Pisa in 1406. He was afterwards employed on several missions: he was sent, together with Cosmo de' Medici, to the congress of Ferrara in 1432, when peace was concluded between the duke of Milan on one side, and Florence and Venice on the other, through the mediation of duke Nicholas of Este. Shortly after this a civil strife broke out between the rival families of the Medici and the Albizzi, and Palla Strozzi joined the party of the latter. The Medici, from the time of Giovanni, father of Cosmo, had taken the popular side, especially in the business of the catasto or census, by which taxation upon property was fixed in proportion to the value of each citizen's property. This measure had been strenuously opposed by the grandi, or older wealthy families, who, having had hitherto the government in their hands, had never paid their proper share of the public burthens, which fell chiefly on the inferior citizens. The Albizzi, who were at the head of this burgher aristocracy, became jealous of the popularity of the Medici. In 1434 they contrived by means of money to have the Gonfaloniere, and the majority of the signori or executive, elected from among their friends. Cosmo de' Medici was then sent for to the town palace by the new Gonfaloniere, and put in prison. He was charged with sundry misdeeds; among others, with having, together with his friends, by their machinations and intrigues, 'caused the republic to undertake an impolitic war against Lucca, which had nearly proved the ruin of the state.' (Fabbroni, *Vita Cosimi Medicei.*) A parliament, or general assembly of the people, was assembled in the square, surrounded by armed men of the Albizzi party: the parliament appointed a balia, or dictatorial commission, which found Cosmo guilty of the various charges brought against him, and sentenced him to banishment, together with his brother Lorenzo and several of his friends. This was the summary mode of settling state matters in the Florentine republic. Rinaldo degli Albizzi, who had himself countenanced the war against Lucca, was most inveterate against Cosmo, and proposed to put him to death; but the more moderate of his party, and Palla Strozzi among others, thought banishment was enough. After a twelvemonth, a reaction took place in favour of the Medici: an executive was chosen from among their friends. Rinaldo degli Albizzi now proposed to his friends to resort to arms to prevent the new executive from taking their seats of office, and to oblige the signoria that was going out to appoint a balia which would appoint an executive favourable to them. Palla Strozzi, too honest or too weak for a partizan, opposed the proposal of Rinaldo as too violent and illegal, and advised to wait and watch the acts of the new executive. This was the ruin of the Albizzi; for the new governors began by imprisoning the late Gonfaloniere, and he summoned the Albizzi to appear at the town palace. Upon this Rinaldo summoned his friends to arms; but many of them declined to obey his call; and Palla Strozzi, after several messages, came out with two armed followers; at which Rinaldo broke out in bitter words of reproach, and Strozzi, after a brief retort, turned his horse's head and went home. Rinaldo remained in uncertainty; he parleyed with his enemies; whilst the signoria had time to send for troops from the country, which occupied all the strong posts in the city. The usual parliament was then assembled, and a balia was appointed, which condemned the Albizzi, Strozzi, and many others to exile, A.D. 1435. Palla Strozzi went to Padua, where he spent the remainder of his life in studious retirement. He died at Padua in 1462, at ninety years of age. 'On arriving at Padua, he devoted himself entirely to study, and found in it a harbour from past storms. He took into his house John Argyropulos and another learned Greek, and allowed them a good salary to read to him Greek works. Argyropulos read to him Aristotle on natural philosophy, and the other read to him other works. Palla Strozzi was himself well acquainted with Greek, and he translated into Latin the works of John Chrysostomus.' (Tito Vespasiano Strozzi, in Méhus's *Life of Ambrosius Traversari.*)

Before his exile, Palla Strozzi had exerted himself to encourage learning in his native city of Florence. Together with Coluccio Salutati and Niccolo Nicoli, he engaged Manuel Chrysoloras to come from Greece to Italy, about 1396; and Strozzi defrayed in great part his expenses, and caused him to be retained at Florence as professor of Greek. Books however were still wanted; and Strozzi sent to Greece for them, and obtained many volumes at his own expense. Among other books, he got the 'Politics' of Aristotle, the 'Cosmography' of Ptolemy, with the maps, the 'Lives' of Plutarch, and the works of Plato. About the year 1428 Palla Strozzi was chosen, with Giannotti Mannetti, to reform the University of Florence, and they established new chairs, and gave a fresh vigour to that institution. It was by Palla Strozzi's advice that Filelfo was engaged as professor with the stipend of 300 crowns, and the new professor soon after had nearly 400 pupils. Strozzi was about to form a public library at Santa Trinita, in the centre of Florence; he

had purchased many books, and had engaged amanuenses to transcribe others for the purpose, when the unfortunate civil factions of 1434-5, and his own exile, prevented the execution of his plan. But yet Palla Strozzi, with Salutati, Manetti, and others, must be considered as having greatly contributed to the revival of classical studies in Italy, before the brilliant æra of the Medici, to whom the whole merit has been commonly attributed. Thomaso Sarzana, afterwards Pope Nicholas V., of illustrious memory, was for a time a guest of Palla Strozzi at Florence, and improved himself in his society. Filelfo was a great friend of Palla, and the friendship was permanent. Timoteo Maffei of Verona, Paolo Cortese, Ercole Strozzi, and others, wrote eulogies of Palla Strozzi.

A collateral branch of the Strozzi lived at Ferrara in the 15th century. Its progenitor was Nanni or Giovanni Strozzi, a Florentine, who removed to Ferrara, and became a distinguished captain in the service of the Marquis Nicholas of Este, was ennobled, and acquired considerable wealth. Nanni left four sons, all of whom applied to literature; but the most distinguished of them was Tito Vespasiano Strozzi, who studied under Guarino da Verona, and became a distinguished scholar and Latin poet. Some of his 'Carmina' were published by Aldus Manutius, and they contain his own biography; others are still inedited. Tito Vespasiano filled several judicial and administrative offices at Ferrara. He was appointed by the duke president of the Council of the Elders, and was sent ambassador to Rome in 1484. As an administrator however it appears from some contemporary chroniclers that he was very unpopular. (*Diario Ferrarese*, in Muratori, *Rer. Ital. Script.*, xxiv.) He died about 1508, and his tomb is in the church of Santa Maria del Vado at Ferrara.

Ercole Strozzi, son of Tito Vespasiano, rivalled and perhaps surpassed his father as a poet. He wrote both Latin and Italian: some of his Latin verses are published together with those of his father. He began a poem in praise of Duke Borso of Este, which he left unfinished. He was a friend of Bembo, Giovio, and other illustrious contemporaries, and Ariosto (*Furioso*, c. 42) has placed him among the excellent poets of his age. The mode of his death was tragical. He had just married Barbara Torella, of a noble family of Ferrara, when, on the 6th of June, 1508, he was murdered one evening as he was returning home, and his body was found on the road with twenty-two stabs, and wrapped up in his mantle. Giovio says that a personage of high rank, whom he does not name, was through jealousy the author of the murder. The Duke Alfonso of Ferrara was suspected. Some of the Latin elegies of Ercole Strozzi resemble those of Ovid in ease and pathos, and in one of them he seems to foretel his own death. He was buried in the same church as his father. His widow, who was also a poet, wrote a sonnet on his death, which is in the 'Raccolta dei Poeti Ferraresi.'

Of the main stock of the Strozzi family which remained at Florence, the most celebrated was Filippo Strozzi, who figured at the period of the fall of the republic. Filippo acted an ambiguous part; he was ambitious, and had great influence through his connections and his great wealth, being possessed of large funds in various banking-houses in several countries of Europe. He was at times the friend and at others the rival of the Medici. He married Clarice, daughter of Piero de' Medici and niece of Leo X., a haughty ambitious woman, who ill brooked to see two illegitimate scions of the family, Alessandro and Cardinal Ippolito, placed by Pope Clement VII. to rule over Florence. Filippo and his wife were the instigators of the popular movement of May, 1527, in which the republic was restored and the two young Medici were reduced to a private condition. Filippo Strozzi was a supporter of the new gonfaloniere Capponi and of the moderate party, in opposition to the violent men who wished to proscribe all the friends of the Medici, and drive matters to extremities. In 1529, by the treaty of Barcelona, between Charles V. and Pope Clement, it was agreed to make Alessandro, the spurious and even dubious son of Lorenzo, duke of Urbino, son of Piero, duke of the Florentine state, and Charles V. agreed to give him in marriage his natural daughter Margaret. An army of mixed Imperial and Papal troops was sent against Florence, which was obliged to surrender, after an obstinate resistance, in which several members of the Strozzi family distinguished themselves, in August, 1530, and Lorenzo Strozzi, brother of Filippo, was one of the commissioners who signed the capitulation on the part of the Florentines. Filippo, who was then at Rome, took part in the various conferences held there by the friends of the Medici in the presence of Pope Clement, concerning the sovereignty to be given to Alessandro. Filippo Strozzi returned to Florence and appeared to be on good terms with the new duke, to whom he even lent money to build a citadel to overawe the city. But Strozzi and his family were too wealthy and too ambitious to be long subservient to a young upstart whose character was despicable. The sons of Filippo were fiery and restive, and his daughter Luisa, who had married Luigi Capponi, having been publicly insulted by one of the duke's courtiers, the latter was assailed one evening and roughly handled by some unknown men. Her brothers, being suspected, were arrested, but afterwards liberated by an order from Pope Clement. The unfortunate Luisa died soon after of poison. Filippo and his sons left Florence for Rome, where Paul III., Clement's successor, felt not the same interest as his predecessor for the Duke of Florence. Cardinal Ippolito de' Medici, an illegitimate son of Giuliano, duke of Némours, being piqued at having been set aside for his cousin Alessandro, encouraged the Florentine malcontents, who assembled at Rome under his auspices, and among whom Filippo Strozzi and his sons were conspicuous. Cardinal Ippolito however died suddenly, not without suspicion of poison. In the year 1535, when Charles V. landed at Naples on his return from the Tunis expedition, Filippo Strozzi and other Florentine emigrants appeared before him and complained of the tyrannical and dissolute conduct of Duke Alessandro, who repaired to Naples with his counsellor Guicciardini, in order to answer their charges. Filippo Strozzi offered large sums of money to the courtiers of Charles, to obtain the removal of Duke Alessandro. At last the emperor decided that the duke should remain, but should give a complete amnesty to the political emigrants, who however resolutely refused the boon, and dispersed themselves among various towns of Italy. Filippo Strozzi repaired to Venice.

In 1537 Duke Alessandro was murdered by his relative Lorenzino de' Medici, who was a descendant of Lorenzo, the brother of Cosmo the elder; upon which the partisans of the Medici contrived to have young Cosmo, another descendant of the same branch, elected prince of Florence, with the approbation of Charles V. The Florentine emigrants were now reduced to despair, and being excited by the agents of France and of Pope Paul III., they resolved to try once more the chance of arms. Filippo Strozzi repaired to Bologna, with his son Piero, a young man of rash courage, who had served in the French armies, and with Baccio Valori, Anton Francesco degli Albizzi, Prior Salviati, and others; from thence they made an irruption into the Florentine territory with about 4000 French and Italian mercenaries. The attempt was badly conducted, and a party of the invaders who had taken possession of the castle of Montemurlo, situated between Prato and Pistoja, allowed themselves to be surprised by the soldiers of Cosmo joined by Spanish troops in the emperor's service, and were totally routed. Piero Strozzi was lucky enough to escape, but Filippo and the other leaders were taken and carried to Florence, where most of them were immediately beheaded. Filippo Strozzi was imprisoned in the very fortress which his money had helped to raise. He was there kept as a prisoner of the emperor, under the care of his lieutenant Don Juan de Luna. Charles V., although he hated Filippo Strozzi and all his family as enemies and partisans of France, still hesitated concerning his doom, as Pope Paul and other great personages interceded for him; Duke Cosmo however was eager for his death. The emperor told the pope that he would spare him if he could show that he was innocent of the murder of Duke Alessandro. Filippo Strozzi was at Venice when the murder was committed at Florence, and it appears certain that he had no previous understanding with Lorenzino: he was astonished and for a time incredulous when the latter told him what he had done, but when he was convinced of the truth, he praised Lorenzino for his deed, and extolled him as another Brutus. However Filippo Strozzi was examined, and put to the torture in presence of Cosmo's chancellor and of Don Juan de Luna; but although he suffered cruelly, being of a weak and sensitive frame, he denied all participation in the murder, and Don Juan de Luna at last ordered the torture to cease. Duke Cosmo however seized upon Giuliano Gondi, an intimate friend of Filippo, who, being under the torture, said that he had heard from Filippo that he was privy to the murder. The

depositions were sent to the emperor, who ordered Don Juan de Luna to deliver his prisoner into the hands of Cosmo. Filippo, being informed of this, preferred killing himself to being put to death by the executioner. He wrote a declaration of his motives, inscribed 'Deo Liberatori,' in which he said that after having been already cruelly tortured, and in order to avoid being induced, through the violence of renewed torments, to accuse some of his innocent relations and friends, as had lately been the case with the unfortunate Giuliano Gondi, he had determined to put an end to his existence, and that he recommended his soul to God, begging of his mercy to give him at least a place with Cato of Utica and other virtuous men who had died in a like manner. He then requested his sons to fulfil his testament, and to repay Don Juan de Luna, the Spanish commander of the fortress, for the many accommodations he had granted him, and to bury his body in Santa Maria Novella by the side of his wife, if it should be permitted; otherwise it might lie wherever they would put it. And lastly, addressing the emperor, he entreated him to inform himself better concerning the condition of poor Florence, and to provide better than he had hitherto done for its weal, unless he intended to ruin the city altogether. He signed this remarkable paper, which was found in his bosom after his death, 'Philippus Strozzi jamjam moriturus,' and added as an epigraph the line from Virgil—

'Exoriare aliquis nostris ex ossibus ultor.'

He then seized a sword which had been left, perhaps by a friendly hand, in his prison, and cut his throat. His end excited a feeling of compassion, mixed with horror, all over Italy. Whatever judgment we may form of the character of Filippo Strozzi, in which ambition and weakness were predominant ingredients, we cannot help compassionating him in his death. The mode of his trial was barbarous and illegal: if he had been tried and executed, like his companions, as a rebel or disturber of the public peace caught with arms in his hands, the sentence would have been plausible, but he was kept in prison for a twelvemonth, and then tried for a deed of which he was innocent. Strozzi was generous and accomplished, was well acquainted with classical literature, and he translated Polybius's treatise 'On the mode of forming Encampments,' and also some apophthegms of Plutarch. Many have mistaken him for a real patriot, which he was not; and Charles V. had well judged him, as well as the other leaders of the Florentine emigrants, when he said to Antonio Doria, who was pleading their cause at Naples in the time of duke Alessandro, 'You little understand these men, Antonio; they do not wish the liberty of their country, but their own greatness; for if we were to remove the duke, they would become themselves lords of Florence, in spite of the other citizens, who really love the liberty of their city, but who could not resist the influence and wealth and power of these ambitious leaders.' (Varchi; Segni; Adriani; the *Life of Filippo*, by his brother Lorenzo Strozzi; and Botta, *Storia d'Italia*.) A curious MS. was discovered not many years since in the possession of the cavalier G. F. Uguccioni of Florence, which is an unedited history by Gian Girolamo de Rossi, a friend of Filippo Strozzi, which contains several particulars concerning his untimely end. (*Antologia di Firenze*, No. 127, July, 1831.) The author says that Cardinal Cibo and Cosmo's mother were the great instigators of Filippo's death, because they thought that his great wealth was dangerous in his hands, but would be less so when divided among his children. Filippo had still at his death 50,000 scudi, or crowns, of income, chiefly in the banks of France, which his enemies could not touch, after the emperor had confiscated the funds which he possessed in Spain, Germany, and Italy.

Piero Strozzi, son of Filippo, after escaping from Tuscany, returned to France, where he was patronised by Henry II. and his consort Catherine de' Medici, and rose to high rank in the French army.

In 1553 he was sent, with the title of 'Lieutenant of the King in Italy,' to Siena, which republic was then at war with Cosmo, duke of Florence, and where there was already a French auxiliary force, joined by a number of Florentine emigrants. His brother Leone Strozzi went also with a French naval force to the coast of Piombino, but was killed while attacking a small fortress near the shore. Piero Strozzi mismanaged the defence of Siena; his great object being to attack Florence, he neglected the main matter, which was to defend Siena; he made useless incursions into the Florentine territory. Being defeated, after a desperate fight near Marciano, by the marquis of Marignano, he retired to Montalcino; and the city of Siena, after sustaining the horrors of famine was obliged to surrender to duke Cosmo, in April, 1555. Piero Strozzi, who in the meantime had been made marshal of France by Henry II., retired to Rome. Soon after, pope Paul IV. having quarrelled with king Philip II. of Spain, the latter sent the duke of Alba from Naples to attack Rome in 1556, and Piero Strozzi was entrusted by the pope with the defence of the city. Strozzi stood out bravely against the Spaniards, till the arrival of the duke of Guise with a French army obliged the duke of Alba to withdraw to Naples. After this Strozzi returned to France, and repaired to the French camp in Picardy to fight against the Spaniards and English. In 1558 he and the duke of Guise took Calais from the English, but shortly after Piero Strozzi was killed by a musket-shot at the taking of Thionville. His son Philippe attained high rank in the French service, and was killed in 1582, in the Azores Islands, whither he had been sent with an expedition by Henry III., or rather by queen Catherine de' Medici, to favour the claims of Don Antonio, claimant of the crown of Portugal against Philip II. of Spain.

Giambattista Strozzi, son of Lorenzo and nephew to Piero, was born at Florence in 1551, and was celebrated during a long life for his learning, his upright character, and his encouragement of useful knowledge. His house was a kind of school, to which young men fond of study resorted, and he gave them lessons gratuitously, and held disputations with them on various subjects of science. Those who were assiduous but poor he supplied with books, board, and other necessaries; and by so doing he greatly reduced his property. He was very intimate with the grand-duke Ferdinand I. and his son Cosmo II. When Urban VIII. was elected pope in 1623, he invited Giambattista Strozzi to Rome, gave him apartments in the Vatican, and delighted in his conversation; and when Strozzi departed to return to Florence, the pope sent him a letter, in which, among other expressions of esteem, he said that he wished that every town of Italy possessed a man like him. After his return to Florence he became blind, but continued to receive in his house and converse with studious men who resorted to him from all parts. He died in 1634, at eighty-three years of age. He was an elegant writer both in prose and in verse; some of his poems and dissertations have been published, but most of his works remain in MS. He began a poem entitled 'L'America,' concerning the discoveries of his countryman Amerigo Vespucci, but left it unfinished. Professor Rosini has inserted many interesting particulars of the life of Giambattista Strozzi, in his historical novel 'La Monaca di Monza.'

There are several other individuals of the name of Strozzi, belonging to various branches of the family, who became known in different parts of Italy for their learning. Francesco di Soldo Strozzi, a Florentine, but residing at Venice, translated into Italian Xenophon's 'History of Greece,' Venice, 1550, and also Thucydides, which last he dedicated to duke Cosmo, Venice, 1545, reprinted in 1563, but of which a much better edition was published at Verona in 1735. Oberto Strozzi of Mantua, a descendant of Tommaso above mentioned, was a patron of literature; he lived in the sixteenth century, and was a friend of Berni, Mauro della Casa, and other learned men. He founded a poetical academy at Rome, called 'dei Vignajuoli,' about 1534, which assembled in his own house, and whose meetings are recorded in high terms by Marco Sabino, in his dedication to Strozzi of the poetical 'Istituzioni' of Mario Equicola, in 1541.

Giulio Strozzi, born at Venice about the latter part of the sixteenth century, wrote poems: among others an epic, entitled 'Venezia Edificata.' He afterwards went to Rome, when he and Cardinal Doti founded an academy called Degli Ordinati, in opposition to that of the Umoristi. Strozzi was made Papal prothonotary, and died at Rome. Ciriaco or Chirico Strozzi, a Florentine, lived in the sixteenth century; he was professor of philosophy and of Greek at Bologna, and afterwards at Pisa, where he died in 1565. He composed a supplement to the 'Politics' of Aristotle, to supply the loss of the ninth and tenth books. Pietro Strozzi, also a Florentine, lived in the seventeenth century, and wrote a theological and controversial work, 'De Dogmatibus Chaldæorum,' with the view of converting the Nestorians of Me-

sopotamia to the church of Rome. (Tiraboschi; Pignotti; Fontanini.)

The palace Strozzi at Florence, built by the architects Da Majano and Pollajolo, in the time of the republic, is a remarkable specimen of the massive and stern style of Tuscan architecture of the middle ages. After the lapse of nearly four centuries it appears as perfect as if it were a recent structure. The colossal entablature which crowns the building is much admired.

STRUENSEE AND BRANDT have acquired celebrity from their extraordinary rise to rank and power, and still more so from their common fate. Their names are inseparably blended in history, and the life of the one can hardly be told apart from that of the other.

JOHN FREDERICK COUNT STRUENSEE was born at Halle in Saxony, on the 5th August, 1737. His father, a divine of some eminence, respected alike for his good qualities and for the orthodoxy of his principles, was professor of theology at the university of Halle, and his mother was the only daughter of John Samuel Karl, physician in ordinary to the king of Denmark. Both his parents took great pains in educating young Struensee, who, after the ordinary course of studies at the school attached to the orphan-house of Dr. Franke, entered the university in 1754, and applied himself to physic. The extraordinary talents which he possessed, and the facility with which he acquired everything bearing upon the science he had chosen, were strongly counterbalanced by licentious habits and a loose way of thinking on matters of religion. Being however under the control of his father, he obtained, with some distinction, his degree of doctor in medicine in 1757. In the same year his father was made pastor primarius at the principal church of Altona, where young Struensee himself obtained the appointment of public physician. Singular success attended him in the practice of his profession, and shortly after his arrival a few literary productions procured him the reputation of an author. He remained in this situation after his father's removal to Rendsburg in 1760, where he had been appointed superintendant-general of Sleswig and Holstein. It is to Struensee's stay in Altona that we must ascribe his knowledge of politics, little as it was, which he so ably employed afterwards in the days of his greatest prosperity. Here also he laid the foundation of that pernicious system of licentiousness which was at once the stimulus of his ambition and the cause of his ruin. It does not appear when he left Altona; but in 1768 we find him appointed to attend the king of Denmark, Christian VII., in his tour through Germany, France, and England. Struensee soon insinuated himself into the good graces of the king, with whose profligacy the loose principles and easy manners of his new physician were in perfect accordance; and such was the ascendency he gained over his royal master, that, shortly after his introduction to him, he ventured to promise Brandt, whose acquaintance he made at Paris, to use his influence in order to procure his recal from banishment. About the same time he met Count Rantzau, who afterwards played so conspicuous a part in the revolution which involved his ruin. At Paris a frequent intercourse with D'Alembert and Voltaire confirmed him in his infidelity, while the profligacy of the higher ranks gave exemption from the fear of scandal. We must not omit that it was during this journey of Christian VII. that the degree of D.C.L. was conferred on the king by the university of Oxford, and that of M.D. on Struensee. Soon after their return to Copenhagen the king himself presented Struensee to the queen Caroline Matilda, the posthumous daughter of Frederic, Prince of Wales, and sister of George III., and promoted him to the rank of privy counsellor. It appears however that the queen did not receive this new favourite of her husband with any marks of attention. It was only through the address with which Struensee reconciled her with the king, from whom she had been alienated in consequence of his excesses, that he became as acceptable to her as to her husband. He received every day from both of them new marks of consideration and esteem, and in 1770, having inoculated the crown-prince (Frederic VI., born in 1768), he was entrusted with his physical education. In his capacity of lecturer to the king, Struensee found ample opportunities of realising his ambitious plans. In order to supplant Count Bernstorff, or rather, to deprive him of his seat in the council of state, he recommended Count Rantzau-Aschbach. Soon afterwards he obtained the recal of his friend Enewold von Brandt, who was raised to the dignity of *maître des plaisirs* and director of the plays, instead of the old favourite Count von Holk. Brandt's polished manners, his easy address, and his lively conversation, were qualities well calculated to promote his favour with the court, where it was of the greatest importance to Struensee that none but his friends should have any influence. It was chiefly through Brandt that he finally succeeded in dismissing Count Bernstorff from the service; many other men of quality were obliged to leave their situations, and the queen dowager Juliana Maria soon found herself without power, neglected by her friends, and slighted by her enemies. The triumph of Queen Caroline was complete; the king behaved to her with deference, and Struensee was now constituted first minister with almost unlimited power. Thus matters stood at the end of 1770, when of the two parties striving for the power which the king had almost resigned, that of the young queen under the guidance of Struensee obtained a decisive victory. In order to be in perfect security, Struensee assigned to Brandt the special office of amusing the king and preventing him from having any conference with his ministers.

It was about this time that the king, urged by Struensee, dissolved the council of state, and instituted in its place a commission of conference (*Commissions conferenz*), which consisted of the presidents of the several branches of public administration. This measure brought all the power into the hands of the prime minister, by whom the members of this new council had been appointed. It changed at the same time the whole Danish constitution by depriving the nobility of their hereditary influence in the affairs of the government, created a universal feeling of disapprobation, and brought much popular odium on Struensee. So limited were the powers of this new chamber, that it could assemble only at certain times, and might be dismissed by the minister; in fact, its members had neither rank, power, nor influence. The imprudence with which this measure was carried into effect could not but prejudice the queen's cause. Among the many enemies which it created, few were so exasperated as Count Rantzau, who, with his seat in the council of state, lost all his power and authority. In order to revenge himself, he joined the queen dowager at Friedensburg. This sudden change in the administration had however the desired effect. Struensee's authority became paramount, and no one ventured to oppose him. The ministers were removed one after the other. All affairs were carried on under the immediate direction of Struensee, and all papers passed through his hands before their ratification by the king. He soon found however that notwithstanding his qualifications for managing the foreign affairs of the kingdom, he had no present means of restoring the exchequer and regulating the home department, both of which had long been declining under the administration of persons utterly devoid of prudence and unacquainted with the resources of the country. His brother C. A. Struensee, member of the college of finance, assisted him in his intended improvements; but the taxes which he imposed produced great destitution among the lower classes, a circumstance which, joined to the despotism exercised over them by a foreigner, increased the number of malcontents and the dissatisfaction of the people. All this time the king was surrounded by libertines, by whom the court was plunged into a profligacy which offended the nation. Meanwhile the attachment of the queen to Struensee exceeded, in appearance at least, the bounds of all moderation. In July, 1771, she was delivered of a princess, and her fears of the infamous reports which were likely to spread from the court of the queen dowager at Friedensburg tended only to place her after this event still more in Struensee's power. This power he shamefully abused. He was raised to the dignity of a count, together with his friend Brandt, and there is reason to believe that much of the enormous wealth of which he died possessed was wrung from the queen's weakness. But though the queen's fears made her silent, it was not so with the press. Its comments on Struensee's proceedings could not be silenced, except by revoking the freedom which he had granted only two years before with the hope of obtaining popularity. This proceeding, as well as the many slights he offered to his former friends, raised the indignation of the people to the highest pitch, and even those who were most attached to him treated him with reserve and coldness. At this crisis too his mental powers began to fail; the daring which had founded his administration, and the quickness in planning and boldness in exe-

enting which sustained it, gave place to a weak and vacillating fear of his daily increasing difficulties. An unimportant mutiny of 300 sailors who had not received their pay had already shaken Struensee's firmness, and was followed by a revolt of the life-guards, whom he had dismissed without any cause.

On this occasion Struensee acted in a manner unworthy of a man in power; he acceded to all the demands of the revolted soldiers, and sought to conciliate them by various means. This disclosure of his weakness of character, to which succeeded measures evidently calculated to secure his personal safety, led the English ambassador to warn the queen of the approaching downfal of the favourite. The regard he felt for her made him even go farther, and request that she would remove Struensee from the court, in order to prevent the catastrophe which he foresaw. But all his entreaties were in vain. The queen trusted too much to Struensee's prudence, who now made some changes in the department of police, with the view of securing himself against any danger. But the purport of those measures was too manifest. The people naturally enough concluded that Struensee was conscious of having slighted the nation, and they began to see that the prime minister was only a fortunate adventurer, whose career was drawing to a close. The partisans of Juliana Maria and her son Prince Frederic regarded this as an opportunity for a coup d'état too favourable to be neglected. They planned a conspiracy with so much secrecy that nothing whatever transpired which could have put Struensee on his guard. Early in the morning of the 17th January, 1772, Queen Matilda, Struensee and his brother, Brandt, and all their friends and adherents, were arrested. The evening before a ball had been given in the royal palace. Struensee, conscious of his own unpopularity, had, according to his custom, surrounded the palace with guards on whose fidelity he thought he could rely. General Eichstädt, who had been gained over by the opposite party, changed the soldiers, substituting his own dragoons in their place. That evening the young queen danced much, and closed the ball with Prince Frederic, about one o'clock. At three in the morning, Colonel Köller, an old enemy of Struensee, sent his officers into the palace, telling them that he had orders from the king to arrest the queen. At the same time the conspirators—the Queen Dowager, Prince Frederic, Rantzau, Köller, Güldberg, and Eichstädt—went into the king's bedchamber, and forced him to sign the order for the seizure of Struensee and his partisans. The unfortunate queen was brought to Kronenburg, where she was confined until the end of May, 1772, when she was set at liberty through the influence of the English government, and was removed to Zelle.

Meanwhile a special commission was formed, in order to try Struensee. The charge, consisting of nine heads, was given to the fiscal-general on the 22nd April, 1772. During Struensee's imprisonment, Dr. Münter succeeded in converting him from scepticism to Christianity: the narrative of his conversion was published, first at Copenhagen, in 1788, and translated into English by the Rev. Mr. Wendeborn, and republished in 1826 by Thomas Rennell. By the sentence, which was pronounced on the 25th April, 1772, Struensee was to be deprived of all his dignities and beheaded. His right hand was to be cut off, his body quartered and broken on the wheel, and his head and hand were to be stuck up on a pole. This sentence was confirmed by the king in every point; and, on the 28th April, Struensee was decapitated, after witnessing the death of his friend Brandt. Struensee was undoubtedly a man of great abilities, capable of great application to business, rapid and decisive in his resolutions, as well as enlarged and patriotic in his views; but he neither possessed the profound policy, the active vigilance, nor the superior judgment requisite for maintaining him in his sudden elevation. Towards the close of his ministry he acted without foresight or address, as if, with the difficulties which augmented around him, he lost his presence of mind and strength of understanding. Voluptuousness was the source of his misfortunes; ambition only contributed to hasten and complete them. His ignorance of the language of the country which he for some time ruled made him commit many mistakes which otherwise he would have avoided. Nevertheless the charges brought against him are heavy, especially that of peculation; he had on various occasions used the public money for the purposes of himself and his friends, and on one occasion he took 60,000 dollars to remunerate himself for his services, and gave an equal sum to Brandt. He also brought the court of Denmark into habits of dissipation, which, from thence, spread throughout the capital. His friend Brandt was formerly chamberlain to Christian VII.; but having calumniated Count Holk, the then favourite of the king, he was banished from court. Struensee, as above stated, recalled him in 1770, and from that period his life was but a copy of that of the prime-minister. He was violent and imprudent, and once so much forgot himself as to strike the king. This crime was forgiven by Christian VII.; it was therefore not this insult to the king's majesty which brought him to the block. That imprudent act served indeed as a pretext on which to found the accusation, but it was not his real crime; he merely suffered for his political and private connection with Struensee. The sentence pronounced on him was similar to that of his friend.

(Jens Kragh Höst, *Der geheime Cabinetsminister Graf Struensee und dessen Ministerium*, which is the best book on the subject: *An Authentic Elucidation of the History of Counts Struensee and Brandt*, 1788, a book containing many unfounded and incorrect assertions; Falken Skiold's *Mémoires*, Paris, 1826; and *A Narrative of the Conversion and Death of Count Struensee*, by Dr. Münter, London, 1826, containing also Struensee's famous confession.)

STRUENSEE, CARL AUGUST VON, brother of the foregoing, was born at Halle, on the 18th of August, 1735, and entered the school of the orphan-house and the university of that town. The wish of his father was that he should study theology; but although he was matriculated in the theological faculty, young Struensee chiefly applied his mind to mathematics and philosophy. In 1756 he was appointed a lecturer at the university of Halle; his lectures on mathematics and Hebrew were well attended, and procured for him some reputation. As early as 1757 he obtained a professorship at the military academy of Liegnitz. The scantiness of pupils which the war had occasioned gave him leisure to study the application of mathematics to the science of war, and in 1760 he published his 'Rudiments of Artillery' (3rd edition, Leipz., 1788). This work procured him the favour of Frederic II., who sent him a great number of young officers whom he was to form for the service. In 1771 appeared his 'Rudiments of Military Architecture,' the third volume of which appeared in 1774; they were republished at Leipzig in 1786. This was the first good book on the subject published in Germany. Meanwhile his brother, who had lately made his appearance at the court of Copenhagen, invited him to that city in 1769. Here he was raised to the dignity of counsellor of justice, and such was his application in the performance of his duties and the judgment with which he avoided all party strife, that after the downfal of his brother, he was set at liberty after a short imprisonment, and permitted to return to his country. Frederic II. received him with kindness, and offered to him the yet vacant place at the academy of Liegnitz; but he refused the offer, and retired to his country-seat of Alzenau, in the neighbourhood of Haynau in Silesia, where he pursued his political and mathematical studies. Here he translated Pinto's 'Essays on Political Economy' (1776), to which he added, in 1777, a second volume containing Essays of his own. These were augmented and republished in three volumes, Leipzig, 1800. It was here also that he wrote 'A Short Description of the Commerce of the principal European States,' a work which was completed by Sinapius, and contains very important notices on the trade of the Prusso-Polonic states. Upon this he was raised to the rank of counsellor of finances, and appointed at Berlin director of the maritime trade. In this capacity he distinguished himself by his extraordinary zeal and his politic measures, and soon effected a rise in the trade, which had much suffered under former administrations. For these services he was made a noble, and received the name of Karlsbach in 1789; two years afterwards he was appointed minister of state and president of the board of excise, in which situation he died, on the 17th of October, 1804.

He was a man of clear and enlarged views, remarkable presence of mind, firm principles, and strict order. He showed himself able to appreciate talent, and this circumstance contributed very much to the amelioration of the departments over which he presided; yet he is not free from the charge of nepotism. He shrank from innovation, and abstained from reforming even where his judgment con-

vinced him that it was necessary to do so. His youngest brother was director of the bank at Elbing about 1777.

STRUMA. [SCROPHULA.]

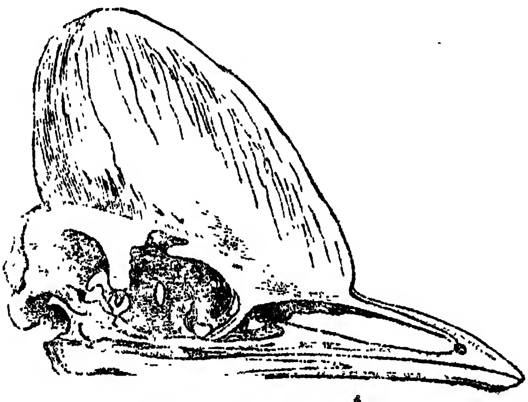
STRUTHIOLA'RIA. [SIPHONOSTOMATA, vol. xxii., p. 54.]

STRUTHIO'NIDÆ, a natural family of terrestrial birds, in which the locomotive energy is thrown into the lower extremities, the wings being in no case adequate to raising the body into the air, and in the majority of instances merely rudimentary. In this respect the genera which compose it are the very reverse of the Humming-birds, Swallows, Albatrosses [ALBATROSS; PETRELS, vol. xviii., p. 46, &c.], Tropic birds, and Man-of-War bird; for in the latter the moving-power resides in the highly developed wings, whilst the feet, especially in the Man-of-War Bird [PELECANIDÆ, vol. xvii., p. 386], are feeble.

The *Struthionidæ* consist of the Ostrich, American Ostrich (*Rhea*), Cassowary, New Holland Cassowary, or Emu, the Dodo (too probably extinct), and that extraordinary bird the *Kivikivi*, or Apteryx, of New Zealand.

Organization.*

Skeleton.—The most remarkable modifications of the *Skull* in this family occur in the Asiatic Cassowary and the *Apteryx*. In the former the bony crest, which is so highly developed in the adult, is hardly perceptible in the young bird, but increases with age, as in the HORNBILL and the Guinea hen. [PAVONIDÆ, vol. xvii., p. 340.]



Skull of Asiatic Cassowary (adult)

Skull of Asiatic Cassowary (young).

In *Apteryx*, according to Professor Owen, the skull is chiefly remarkable for its smooth expanded elevated pyriform cranial portion, the total absence of supra-orbital ridges, the completeness and the thickness of the inter-orbital septum, the great development of the ethmoid, the small size of the lachrymal bones, and the expansion of the nasal cavity behind these bones. The tolerably semicircular occipital region differs from that of other *Struthionidæ* in the greater relative extent of its base, and in the comparatively slight lateral sinuosities due to the temporal depressions. There is no vertical notch at the upper part of the single hemispherical tubercle in the basi-occipital for articulation with the atlas, as in the *Ostrich* and *Emu*, but it is entire, as in *Rhea*; the plane of the occipital foramen also has the same aspect as in that bird, in which it is more nearly horizontal than in the *Ostrich*. The supra-occipital plate forms a somewhat angular projection, corresponding with the small cerebellum, and is bounded on each side by a vertical vascular groove terminated by a foramen above and below; the ex-occipitals extend outwards and downwards external to these grooves in the form of obtuse processes compressed in the antero-posterior direction, and are slightly convex behind and concave in front, where they form the back part of the wide meatus auditorius externus. The occipital bones, and also the surrounding bones, were anchylosed together. The angle between the posterior and superior regions of the cranium can hardly be said to be produced into a ridge. The superior region is smooth, convex, and separated from the temporal depressions by a narrow ridge, rather more marked than the occipital ridge. The sagittal suture crosses a little behind the middle of the upper part of the cranium. In one cranium Professor Owen found the left half of this suture persistent; but in another, that of a male, all the sutures were obliterated. The persistent sutures were more denticulated than those in the skull of a young *Ostrich*. The superior region is continued into the lateral regions by a continuous curvature, so that the upper part of the small orbital cavity is convex, and its limits undefinable, there being no trace of supra-orbital ridge, nor of antorbital or postorbital processes. This structure, Professor Owen observes, is quite peculiar to the *Apteryx* among birds, but affords a very interesting resemblance between it and the monotreme *Echidna*. The slender zygomatic process sent forwards by the temporal bone most resembles that of *Rhea* in its small relative development. Between the frontal bones, which gradually contract to their junction with the nasal bones, a small part of the ethmoid may be traced. The narrow frontal region is traversed by a mesial longitudinal depression. The ethmoid bone is remarkably expanded; its cells, instead of being restricted to a narrow vertical septum of the orbits, as in the diurnal *Struthionidæ*, occupy not only the ordinary orbital space, but extend outwards for more than two lines beyond the lateral boundaries of the anterior part of the frontals. A small process extends from the frontal to the side of the expanded ethmoid, anterior to the orbital foramina, which are distinct and remarkably wide apart, and the ethmoid, which is nine lines in breadth, is also supported anteriorly by a similar anchylosed conjunction with the lachrymal bone. The Professor remarks that the nearest approach to this peculiar structure of the *Apteryx* is made by the *Ostrich*, in which last the interorbital septum, though much thinner than in the *Apteryx*, is also occupied by ethmoidal cells, and is thicker than in any of the other large *Struthonidæ*. The *Ibis*, he observes, offers a striking contrast with the *Apteryx* in this respect, the interorbital osseous septum being almost entirely absent; and it also differs widely in all the other parts of the cranium already noticed. In the posterior region of the skull of the *Ibis* the long covering of the cerebellum is, as he states, in great part defective: in the superior part, the cranial parietes above the cerebral hemispheres form two convexities separated by a middle longitudinal depression, and the narrow space between the supra-orbital ridges is occupied by the impressions corresponding to the nasal or supra-orbital glands; the whole cranium also is much higher and shorter in proportion to its breadth than in the *Apteryx*; and Mr. Owen remarks that the *Ibis*, in thus differing from the *Apteryx*, deviates also from the other *Struthionidæ*.

The base of the skull of *Apteryx* exhibits all the peculiarities characteristic of the Struthious birds. The body of the sphenoid sends out two processes on each side externally; the posterior of these abuts against the tympanic bone, and the anterior one by a flattened oval articular surface against the pterygoid bone. Professor Owen points out that the latter processes exist, but are much more feebly developed in the *Ibis*, and that in most other birds, including the *Grallæ*, they are wanting, whilst they are well developed in the Lacertine *Sauria*. A compressed vomerine process is continued forwards from the anterior part of the basi-sphenoid, and this process is anchylosed to the under part of the expanded and cellular ethmoid.

The olfactory depressions in the interior of the cranium are proportionally larger than in other birds, and the olfactory nerve, instead of being continued along the upper part of an interorbital septum by a bony canal or groove to the nasal cavity, immediately passes by many perforations through a cribriform plate to the complex and extensive pituitary surface of the ethmoid bone.

Both internally and externally the optic foramina are distinct and half an inch apart; they are perforated not in the sphenoid ala, but in the inflected margin of the frontal bone. 'In these peculiarities the *Apteryx* differs from all the rest of its class; each optic foramen however transmits not only the optic nerve and ophthalmic artery, but also the third, fourth, first branch of the fifth, and sixth nerves, as in

* The anatomy of *Apteryx* is entirely taken from Professor Owen's paper in the second volume of the 'Transactions' of the Zoological Society of London.

most other birds. Of these nerves the fifth is the largest, and it is continued forwards to the nasal canal, through two foramina, one circumscribed externally by the process already mentioned, which extends from the frontal to the ethmoid; the other, by the corresponding process of the lachrymal. The pituitory fossa, or sella turcica, is a very deep semi-oval depression; the common internal orifice of the two carotid canals communicates with its posterior part. On each side of the anterior part of the floor of the cranium, which supports the medulla oblongata, there is an oblique slightly curved groove, terminated at its anterior extremity by the *foramen rotundum*, at its posterior by the *foramen ovale*. These *foramina* are situated between the basilar and alar elements of the sphenoid; they are nearly of equal size, and are relatively longer than in the diurnal *Struthionidæ*. The foramen rotundum is not only distinct, but is farther apart from the *foramen opticum* than in any other bird. The petrous bone projects internally in the form of a thin semicircular plate of bone, commencing at the foramen ovale and extending backwards to the foramen auditorium internum, which it overhangs: this plate gives attachment to the tentorium. There is not any corresponding bony ridge developed from the upper wall of the cranium in the line of origin of the falx, as in many of the gallinaceous birds. The anterior or cerebral division of the cranial cavity is larger in proportion to the posterior than in most other birds.'

The tympanic bone is trihedral, subcompressed, and sends forwards into the orbit a process longer and more slender than that in the larger *Struthionidæ*: its upper articular surface is a transversely extended convex condyle, playing in a corresponding cavity internal to the base of the zygomatic process. The opposite and expanded extremity presents two distinct articular convexities for the lower jaw, the inner being the largest; a small but deep depression for the reception of the deflected extremity of the jugal bone exists above the external convexity. Between the orbital process of the tympanic and the transverse process of the sphenoid bones, the posterior extremity of the pterygoid bone is securely wedged in, and, advancing forwards, expands, as in the other *Struthionidæ*, into a thin plate of bone, which is bent upon itself with its concavity turned inwards, and is continued by anchylosis into the palatine bones, so that the limits between them are indefinable. So also the palatine bones are confluent with the maxillaries: the former are pierced by two narrow elliptical posterior nasal foramina, about three lines in length, over which the external margin of each palatine bone arches from without inwards. These overarching laminæ gradually approach each other, as they advance forwards, and meet about an inch anterior to the nasal foramina, from which an imperforate plate of bone, with a narrow median fissural impression, and composed of the confluent palatal processes of the maxillary and intermaxillary bones, is continued to the end of the beak, the limits between those bones being indicated by two fine oblique lines arising at the outer margin of the roof of the mouth, about two and a half inches from the apex of the beak. The jugal style in *Apteryx* consists of a single slender, compressed, twisted bone, anchylosed with the maxillary bone in front, and terminated behind by an obtuse deflected extremity, which is received into a corresponding vertical cavity in the upper part of the outer process of the tympanic bone. In the full-grown Ostrich this bone is separable into a zygomatic and malar portion. By the mode of attachment adopted in *Apteryx*, the tympanic bone offers increased resistance to the pressure transferred to it by the lower jaw, at the same time that it gives additional strength to the upper mandible. As in the other *Struthionidæ*, it is continued backwards in the same line with the upper maxillary bone, and is not bent downwards at its junction with the maxillary, as in the *Ibis* and other *Grallæ*. The superior maxillary bone is singular, presenting the form of an elongated triangular plate of bone nearly perfectly flat, imperforate, and continued with the intermaxillary by uninterrupted ossification. Of the *Struthionidæ*, *Rhea* comes nearest to *Apteryx* in the structure of this part of the skull; but in *Rhea* large *foramina* perforate the maxillary plate, which sends upwards on each side a process to join the lachrymal. The superior maxillary bones of the *Ibis* are slender round styles, with a wide interspace between them. Two compressed plates of bone, descending obliquely forwards from the anterior extremities of the frontals, and articulated below to a small depression in the maxillary plate, each pierced by a single small foramen, represent the lachrymal bones in *Apteryx*. The continuous bony piece formed by the frontal, nasal, and intermaxillary bones is too strong to admit of any elastic yielding movement between the upper jaw and cranium. The nasal and the upper or mesial portions of the intermaxillary bones form an elongated depressed narrow process, convex above, with external margins bent inwards beneath the long nasal passages, of which they form the outer and part of the lower boundaries.

The usual ornithic characters, with the Struthious modifications traceable in the individual peculiarities, are presented in the lower jaw of *Apteryx*. 'The transversely expanded angular and articular extremities offer the inwardly extended process for the attachment of the *pterygoidei* muscles; the superior transverse plate, behind the articular surfaces, is thin and concave towards the *meatus auditorius externus*, and is lined by the mucous membrane of that passage, of which it forms part of the bony parietes. There are two distinct narrow oblique articular surfaces, concave in the longitudinal and convex in the transverse directions; the internal one is the largest, and behind this there is a small excavation, into which a small process of the air-sac lining the tympanum is continued; and this is the only part of the skeleton not immediately concerned in the formation of the organs of hearing or smelling into which air is admitted. The entry to the air-cells, in the lower jaw of the *Ostrich*, is situated in the part corresponding to the above depression or sinus in the jaw of *Apteryx*. Traces of the compound structure of the lower jaw are very evident in that of the *Apteryx*, and the limits of the angular, articular, and coronoid pieces may be in part defined. There is a linear vacancy, bounded by the surangular and angular pieces behind, and by the bifurcate commencement of the mandibular or dentary piece in front: the surangular is compressed, and sends upwards a very slightly elevated coronoid ridge. A second narrower fissure occurs between the thick opercular or splenial element and the upper fork of the mandibular piece. The opercular piece reaches to the posterior part of the symphysis, as in the *Ostrich*, and the rest of the lower jaw in front of this part is formed by the two anchylosed mandibulars. In the extent of this anchylosed symphysis, the *Rhea* makes the nearest approach to the *Apteryx* among the *Struthionidæ*, and the two impressions which diverge from the back part to the front of the symphysis are present in both the *Rhea* and *Emeu*, as in the *Apteryx*. The lower jaw of the *Apteryx* differs from that of the *Ibis* in its greater posterior expanse, its more depressed form, the lower coronoid plate, the narrower fissure between the angular and surangular pieces, and the absence of the mesial furrow, extending in the *Ibis* to the end of the symphysis.'

Vertebral Column.—The number of the *cervical* vertebræ in the *Ostrich* is eighteen, in the *Cassowary* sixteen (true), in *Rhea* sixteen (not fourteen, as Cuvier states), in the *Emeu* nineteen, in the *Apteryx* fifteen only; and in the latter there are nine dorsal, and twenty-two remaining vertebræ in the lumbar, sacral, and caudal regions: the spinal column of *Apteryx* is relatively stronger, especially in the cervical region, than it is in the larger *Struthionidæ*. The length of the cervical region, the vertebræ of which present the usual ornithic characters, is seven inches: that of the *dorsal* region four inches, and that of the portion of the column behind the dorsal vertebræ included between the ossa innominata, three inches. The structure of the vertebræ is minutely detailed by Professor Owen, who observes that the close resemblance of the bird to the reptile in its skeleton is well exemplified in the young *Ostrich*, in which even when half grown the costal appendages of the cervical region continue separate and moveable, as in the *Crocodile*: those the Professor found anchylosed to the first fifteen vertebræ in *Apteryx*.

The nine caudal vertebræ of *Apteryx* are deeper and project farther below the posterior portions of the iliac bones than in the other *Struthionidæ*. The spinal canal is continued through the first five of these vertebræ, which, as they descend, progressively increase in lateral and diminish in vertical extent, and are all moveable upon each other except the two last, which combine to form a vertebra analogous to the expanded terminal vertebræ in other birds, but which in *Apteryx* exceeds the rest only in its greater length, and gradually diminishes to an obtuse point. Professor Owen proceeds to remark that in the *Ostrich* the

corresponding vertebra is expanded for the support of the caudal plumes, but that in *Apteryx* it offers the same in conspicuous development as in *Rhea* and the *Emeu*.

The first dorsal *rib* in *Apteryx* is described as a slender style about an inch in length, and the rest as remarkable for their breadth, which is relatively greater than in any other bird; the *Cassowary*, in this respect, is stated to approach nearest to the *Apteryx*. 'The second, third, fourth, and fifth ribs are articulated with the sternum through the medium of slender sternal portions; that of the sixth also reaches the sternum, but is attached only to the external rib anterior to it, and a considerable interspace exists between its unattached extremity and that of its corresponding vertebral rib. In the first simple and floating rib, the part corresponding to the head and neck, as usual, is not developed, and it is attached to the transverse process by the part analogous to the tubercle. In the second rib a short and strong cervix terminated by a hemispherical head is given off below and in front of the tubercle, and works in a corresponding socket at the anterior margin of the vertebra. The head and tubercle, with the points of the vertebræ to which they are attached, intercept large foramina corresponding to the vertebral foramina in the cervical region. Immediately below the tubercle the rib suddenly expands, and then gradually narrows to its lower end; the neck of the rib increases in length in the third and fourth pairs, and diminishes in the last two; the sixth rib begins to lose its breadth, and the rest become narrower to the last. The bony appendages to the vertebral ribs are developed in the second to the eighth inclusive: they are articulated by a broad base to a fissure in the posterior margin of these vertebral ribs a little below their middle part; those belonging to the third, fourth, fifth, and sixth ribs are the longest, and overlap the succeeding rib: these processes are not anchylosed in the specimen described. The *Rhea* comes nearest to the *Apteryx* in the size of these costal appendages. The first four sternal ribs are transversely expanded at their sternal extremities, which severally present a concave surface lined with smooth cartilage and synovial membrane, and playing upon a corresponding smooth convexity in the costal margin of the sternum, which thus presents four enarthrodial joints with capsular ligaments on each side. This elaborate structure is not however peculiar to the *Apteryx* among birds, but relates to the importance of the movements of the sternal ribs, which are the centres upon which the respiratory motions hinge,—the angles between the vertebral and sternal ribs, and between these and the sternum, becoming more open in inspiration when the sternum is depressed, and the contrary when the sternum is approximated to the dorsal region in expiration.'

In the *Struthionidæ* we look in vain for the deep crista or keel which so strongly marks the well-developed ornithic character, especially in the diurnal birds of prey, the larger sea-birds above alluded to, and the humming-birds. Such a foundation would be worse than useless where there is none of the machinery of flying to be worked, and the utmost demand on the anterior extremities goes no farther than their aid in balancing the body when the bird runs. We accordingly find that in the larger *Struthionidæ* (Ostrich, Cassowary, &c.) the breast-bone presents a plane and uniformly arched shield-like surface, not unlike, in some of the family, the Cassowary and Emeu for instance, to a Highlander's target on a reduced scale. But in the *Apteryx* this low development is reduced to its lowest grade. In its small size, and in the total absence of a keel, it resembles, Mr. Owen observes, that of the Struthious birds generally, but differs in the presence of two subcircular perforations on each side of the middle line, in the wide anterior emarginations, and in the much greater extent of the two posterior fissures. The anterior margin, he tells us, presents no trace of a manubrial process, as in the *Ostrich*: on the contrary, the wide interspace between the articular cavities of the coracoid is deeply concave; in the extent of this interspace, he remarks, the *Rhea* most resembles the *Apteryx*, but its contour is almost straight; whilst, in the *Cassowary*, the space is narrower, but deeply notched. The articular surface for the coracoid is an open groove, which in the fresh state is covered with articular cartilage; and, external to the groove, the anterior angles of the sternum are produced into two strong triangular processes with the apex obtuse. The thickened costal margin, when viewed anteriorly, presents an undulating contour, from the presence of the four articular convexities, for the sternal ribs and the intermediate excavations. The sternum of the *Emeu*, Mr. Owen remarks, presents a similar appearance. The breadth of each sternal perforation is, he adds, nearly equal to that of the intervening osseous space, and in the specimen described they were not quite symmetrical in position. The posterior notches equal in extent one half the entire length of the sternum, and the external boundaries of these notches curve towards each other. These notches exhibit a slight want of symmetry in form, position, and extent.

There is no true *furcula* in the *Struthionidæ*, but the *Ostrich* and *Cassowary* have on each side of the front of the chest an elongated flat bone consisting of a rudiment of the furcula, with the clavicle and scapula consolidated into one piece. The two branches of this rudimentary furcula are very short, and never united in the African *Ostrich*, but anchylosed with the bones above mentioned. In the *Cassowary* there are merely two little processes from the side of the clavicle: these are the rudiments of the branches of the fork. In the *Emeu* two very small thin bones are attached to the anterior edge of the dorsal end of the clavicles by a ligament, and are directed upwards towards the neck: there they are fastened to each other by a ligament, but have no connection with the sternum. In the *Apteryx* the *scapula* and *coracoid* are anchylosed; and a small perforation anterior to the articular surface of the humerus indicates the separation between the coracoid and rudimental clavicle, of which, Professor Owen states, there is not otherwise the least trace. The coracoid, he adds, is the strongest bone; and its inferior expanded extremity presents an articular convexity, adapted to the sternal groove before described. The third rib is reached by the scapula, which is a simple narrow plate of bone, one inch in length, slightly curved, and expanded at both ends, chiefly at the humeral articulation.

The true *wing bones* are best developed among the Struthious birds in *Rhea*; the next best development is in the *Ostrich*: in the *Cassowary*, *Emeu*, and *Apteryx*, the lowest development of these bones is exhibited. In the latter the *humerus* is a slender, cylindrical, styliform bone, one inch and five lines in length, and slightly bent. At the two extremities it is slightly expanded, but most at the proximal end, which supports a transverse oval articular convexity, covered with smooth cartilage, and joined by a synovial and capsular membrane to the scapulo-coracoid articulation. Beyond each end of the humeral articular surface is a small projecting tuberosity. The distal end of the humerus is articulated by a true but shallow ginglymoid joint with the rudimental bones of the antibrachium, and both the external and internal condyles are slightly developed. The slender *radius* and *ulna*, each nine lines in length, are almost straight and cylindrical. Above the articular surface of the ulna a feebly developed *olecranon* is projected. A minute carpal bone, two metacarpals, and a single phalanx, which supports the long curved obtuse alar claw, complete this rudimental hand, which is seven lines in length, including the claw, and that measures three lines and a half. To the ulna and metacarpus a few short and strong quill-feathers are attached by ligament.

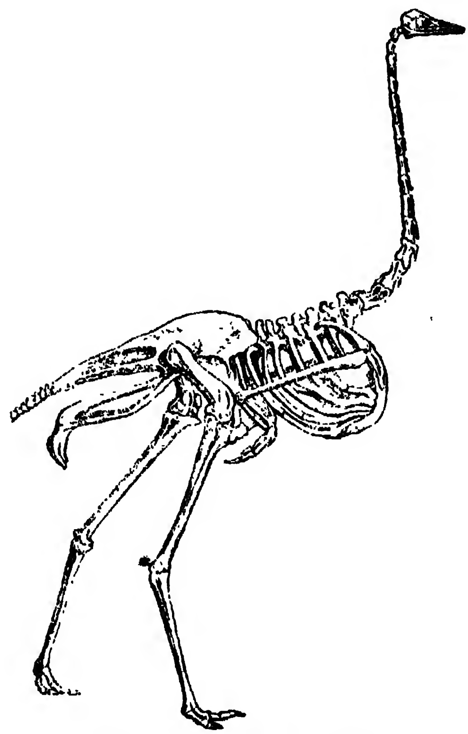
Strongly contrasted with the flattened sternum and the dwindled anterior extremities are the strongly developed *pelvis* and posterior limbs of the *Struthionidæ*. The pelvis of the ostrich bears some resemblance to that of the extinct quadrupedal *Mylodon*, of which there is now a noble skeleton in the museum of the Royal College of Surgeons. In this part of the osseous system we have ample fulcra for those powerful muscles which render the larger Struthious birds swifter than the swiftest. The iliac bones of *Apteryx* resemble those of the rest of the tribe in size and shape, and are four inches and three lines in length. There is a slight anterior concavity on the outer surface, and this concavity passes into a convexity posteriorly, the two surfaces not being separated by the transverse elevation which exists above the acetabulum in the four large *Struthionidæ*. Between the posterior extremity of the ilia and the first three caudal vertebræ, a distinct epiphyseal piece of bone is wedged in. The ischium extends backwards parallel with the sacrum, in the form of a thin plate of bone, which slightly expands to its free and truncated extremity. The pubic element is a slender bony style, connected by ligament to the end of the ischium, but attached by bone at its acetabular extremity only. A short pointed process extends from the anterior margin of the origin of the pubis. In comparing the pelvis of *Apteryx* with that of the large

Struthious birds, Professor Owen observes that the ischia do not meet below the sacrum, as in the *Rhea*, but are more distant from that and the iliac bones than in any of the *Struthionidæ*; the pubic bones, he remarks, are not joined together at their distal extremities, as in the *Ostrich*; nor are the extremities of the ischia anchylosed to the superincumbent ilia, as in the *Cassowary*. It is the *Emeu*, he adds, that comes nearest to the *Apteryx* in the structure of the pelvis, but it also differs in the complete bony boundary of the foramen, which transmits the tendon of the obturator internus, and which is completed posteriorly by ligament in *Apteryx*. The acetabulum, he observes, communicates, as usual, by a wide opening with the pelvis, and a surface covered with a cushion of thick cartilage is continued from its posterior and upper part.

The great length of leg in the *Struthionidæ* is produced, as in the true wading-birds, by the tibia and common bone of the tarsus and metatarsus; for the femur is comparatively of short dimensions.

The fibrous capsule of the hip-joint of *Apteryx* is very strong; the synovial membrane is reflected from it upon the upper margin of the trochanter and upper part of the short neck of the femur, as well as upon the ligamentous bridge, continued from the upper and extended margin of the acetabulum to its anterior part. The very large *ligamentum teres* is short, and consists of an infundibular process of synovial membrane, reflected from the circumference of the acetabular perforation to that of the depression on the head of the femur: this synovial sheath encloses two distinct ligaments, which are twisted about each other like the crucial ligaments of the knee-joint. One of the ligamentous bands passes from the upper margin of the acetabular perforation to the lower edge of the femoral depression.

The small round head of the *femur* (which last possesses in *Apteryx* the usual ornithic character, and is three inches nine lines in length) is supported on a very short and thick neck, placed at right angles to the great and single trochanter, and presents at its superior part a large depression for the strong and complicated ligamentum teres; its shaft is slightly bent with the convexity forwards, and this is increased by a thickening at the anterior part of the middle of the shaft. The condyles are separated anteriorly by a wide and deep groove, and, behind, by a triangular depression. The outer condyle is the largest, and has an external groove for the articulation of the head of the fibula: the inferior compressed border of the condyle is wedged in between the tibia and fibula. Two angular and strong ridges are developed from the anterior part of the expanded end of the *tibia*, which is five inches in length: the external one affords attachment to the fascia and to the expanded tendon of the rectus femoris latissimus; to the internal ridge is affixed the ligament of the small cartilaginous *patella*. The knee-joint is very complex. The broad and thin internal lateral ligament gives origin to part of the soleus, and is attached to the internal semilunar cartilage. This fibro-cartilage divides at its anterior extremity into three ligaments: one broad and thick, going to the posterior surface of the rotular cartilage, and representing the ligamentum mucosum; the other two inserted at the interspace of the condyles. A very strong ligament arises from the inner edge of the tibia beneath the internal semilunar cartilage, and is also attached to the same interspace. A strong external lateral ligament extends between the outer condyle and the head of the fibula; and beneath or within this there is a second ligament, which passes from the outer *condyle* to the external semilunar cartilage. From the anterior parts of this cartilage a thick ligament extends to the back part of the ligamentum patellæ. From the back part of the external semilunar cartilage a posterior crucial ligament extends to the condyloid interspace; and, lastly, a strong ligament arises from the fore part of the head of the tibia, and passes upwards and backwards, to be inserted, with the preceding ligament, into the back part of the interspace of the condyles. The head of the tibia sends down an angular ridge posteriorly: the shaft is rounded, slightly compressed, converging to a ridge externally, to which ridge the *fibula* is attached in two places, beginning half an inch below the head of the fibula, and continuing attached for ten lines: then again becoming anchylosed, after an interspace of nine lines. In one specimen, Professor Owen found the fibula also anchylosed to the tibia by its expanded and thick proximal extremity; in descending it rapidly diminishes in size, and gradually disappears towards the lower fourth of the tibia, whose distal end presents the usual trochlear form, but the anterior concavity above the articular surface is in great part occupied by an irregular bony prominence. A small cuneiform tarsal bone is wedged into the outer and back part of the ankle-joint. The strong anchylosed tarso-metatarsal bone is two inches three lines in length, and the upper articular surface is formed by a single broad piece. Professor Owen points out that the original separation of the metatarsal bone below into three pieces is plainly indicated by two deep grooves on the anterior and posterior part of the proximal extremity; and that



Skeleton of Ostrich. (Pander and D'Alton.)

Skeleton of Apteryx. (Owen.)

the intermediate portion of the bone is very narrow anteriorly, but broad and prominent on the opposite side. The bone is flattened from before backwards, and expands laterally as it descends, dividing at its distal extremity into

three parts, with the articular pulleys for the three principal toes. The surface for the articulation of the fourth or small internal toe is about half an inch above the distal end, on the internal and posterior aspect of the bone. A small ossicle attached by strong ligaments to this surface gives support to a short phalanx, which articulates with the longer ungueal phalanx.

In the *Ostrich* the number of toes is two only; the *Cassowary* and *Emeu* have each three. The *Apteryx*, and, according to the figures and remains, the *Dodo*, have a fourth. In the *Apteryx* the number of phalanges of the three greater toes follows the ordinary law; the inner toe having three, the middle four, and the outermost five phalanges.

Digestive System.—Though proper salivary glands can hardly be said to exist in birds, they have various glands for secreting a copious supply of mucus for the defence of the tender lining of the mouth and fauces. In the ostrich there are two flattened bodies at the upper and back part of the palate, which may be compared to tonsils. Their surface is covered with innumerable foramina from which a tenacious mucus may be pressed.

The crop in the *Struthionidæ* is of great size. The bulbus glandulosus or proventriculus is situated before the entrance of the œsophagus into the proper stomach, and is so large and so modified in form in some of the species, the ostrich for example, as to give it the appearance of a second stomach; indeed Valisnieri, in his 'Anatomy of the Ostrich,' calls it the first stomach. Mr. Lawrence found the œsophagus of an ostrich which he dissected dilated into an immense bag capable of holding several pints of water, and five or six times larger than the gizzard itself, which was placed on the right and anterior part of this dilatation. The glands did not surround the tube, so that, Mr. Lawrence observes, the term 'zone' would be here inapplicable. They formed, he tells us, a long but narrow band, commencing at the termination of the œsophagus, and running along the front of the bag towards the gizzard. This band measured about twelve inches in length and not more than three at its greatest breadth. The size of the individual glands varied: they were largest in the middle, and decreased towards either margin of the band. Some of them equalled a large pea, and their openings were in proportion. They were arranged in close apposition to each other, and the inner surface of the pouch was covered by a continuation of the insensible lining of the gizzard, which separated very easily from the surface. The cæca in the ostrich are characterized by a remarkable spiral valve, and the villi in its small intestine are rather flat thin laminæ than villi; but they are at the same time long and numerous, presenting a very elegant structure. The large intestine of the ostrich presents a remarkable deviation from the structure usually seen in birds; for the surface of that intestine is in them generally uniform on its surface, whereas in the ostrich the large intestines, which are very long, have numerous transverse folds, like the valvulæ conniventes of man.

In the museum of the Royal College of Surgeons in London, No. 533 of the Physiological Series shows a portion of the gizzard, with the pylorus of the ostrich, exhibiting the valvular structure at that part, adapted to prevent the escape of the contents of the gizzard until they have been sufficiently comminuted, if alimentary, or diminished in size by friction of pebbles, &c. swallowed for the purposes of trituration. No. 533 A is the stomach of an Emeu (*Dromaius Novæ Hollandiæ*) laid open. The gastric glands, of large size, are seen scattered over the whole inner surface of the proventriculus, and terminating towards the gizzard by two oblique lines. Between the proventriculus and gizzard intervenes a considerable space, which may be termed the membranous portion of the stomach, in contradistinction to the muscular part or gizzard. The entrance and outlet of the latter cavity, which are closely approximated in all birds, are here of such large size and so blended together, that the membranous portion of the stomach appears to pass into the intestine by a continuous canal, and the gizzard seems to be simply a lateral dilatation: its parietes are thickest at its commencement; at the remainder they are comparatively weak and thin. A portion of the thick cuticle which lined this cavity is left. A circular valve intervenes between the stomach and duodenum; the latter commences by a considerable dilatation. No. 533 B is the stomach of a Cassowary (*Cassuarius galeatus*) laid open, and constructed on the same type as the preceding. The gastric glands are dispersed over the proventriculus with a similar degree of uniformity; but they are smaller, and their lower boundary is transverse. The cuticular lining being here preserved, shows that the membranous part of the stomach is lined with a thin layer of that substance, which commences just where the glandular part terminates. The gizzard has a similar lateral position, out of the direct passage of the food, as in the Emeu; but is evidently more muscular. Its inner surface is thrown into irregular longitudinal rugæ. The pylorus is protected by a similar circular valve; but the commencement of the duodenum is still more capacious than in the Emeu, reminding one of the pyloric cavity in many of the *Grallatores*. Beyond this dilated part the duodenum presents some transverse rugæ, analagous to valvulæ conniventes. 533 C is the stomach of the Nandu or American Ostrich (*Rhea Americana*, Lath.) laid open. Here a very different type of structure presents itself. The gizzard is more capacious, and, as in the gallinaceous birds, is continued directly from the proventriculus, with the intestine arising near the entry. The parietes of the gizzard, though strongly muscular, are not remarkable for their thickness; the cuticular lining is very thick, and is here well preserved, showing its irregular surface so well adapted for triturating. The gastric glands are more complex than in the preceding preparations, and are aggregated in a mass of a circular form; their orifices are very conspicuous. The pylorus is protected by a projecting valve irregularly ribbed. The duodenum is of moderate width, and has been, here, partially inverted to show the peculiar flocculent character of its lining membrane. 533 D is a longitudinal section of the membranous and muscular parts of the stomach of an ostrich (*Struthio Camelus*, Linn.). The parts have been minutely injected, and the cuticle, which separates very readily after death, has been almost entirely removed, showing the vascular surface beneath. The gizzard, as in the preceding species, is a direct continuation of the membranous part, but its parietes are much thicker. The slit-like form of the pylorus, and its ribbed valve, may be seen on one side of the preparation; and on the opposite side is seen the duodenum laid open to show its villous inner surface.

Sir Everard Home, who presented the preparations above mentioned, thus describes the stomach of the ostrich:—'In the African ostrich the gastric glands are similar in structure to those of the American, only the processes belonging to each gland are much more numerous: they are in general twenty or thereabouts. The cardiac cavity into which they open is not only very large, but is continued down in the abdomen below the liver to a considerable length, and then is bent up to the right side, and is there connected with a gizzard, the digastric muscle of which is as strong as in granivorous birds in general. This gizzard is situated so high up, as to be nearly on a level with the termination of the œsophagus. The cardiac cavity is everywhere lined with a thin cuticle, except where the ducts of the gastric glands open. Their orifices occupy an oval space on the left side, extending from the top to the bottom of the cavity, and about four inches broad. The size of the gizzard is small, when compared to that of the bird. The grinding surfaces do not admit of being separated to any great distance from one another. On one side there are two grooves, and two corresponding ridges on the other. Beyond the cavity of the gizzard is an oval aperture with six ridges, covered with cuticle, which oppose the passage of the contents of the cavity till they are reduced to a small size. In the Cassowaries and American ostrich the stones and other hard bodies which those birds swallow, must, from their weight, force their way into the gizzard, which has a cavity adapted to receive them; but in the African ostrich all such substances must remain in the cardiac cavity, both from its being the most depending part, and from the cavity of the gizzard being too small to admit of their entering it. The cardiac cavity, in the instance which I examined, contained stones of various sizes, pieces of iron, and halfpence; but between the grinding surfaces of the gizzard there were only broken glass-beads of different colours, and hard gravel mixed with food.' (*Lect. on Comp. Anat.*) No. 533 E of the series above noticed is a bottle containing a great quantity of pebbles from an ostrich's gizzard, and No. 533 F is another, containing pebbles and an iron nail, from another gizzard of the same kind. No. 677 to 683 both inclusive are preparations showing the flattened elongated villi, the vascularity of the villous membrane, the veins and arteries and other phenomena of the small intestines of the ostrich.

No. 654 is also a portion of the small intestine of the same bird injected, and showing two processes of peritoneum going off at right angles to the mesenteric process, from the sides of the intestine and trunks of the great vessels. A portion of the peritoneal coat has been removed from one end of this preparation to show the external longitudinal and internal circular layers of the muscular tunic. No. 818 is the pyloric end of the stomach and commencement of the duodenum of an ostrich, showing the entrance of an hepatic duct close to the pylorus, and in a direction inclining to that orifice. The thick cuticle of the gizzard and the valvular structure of the pylorus are also well displayed in this preparation.

The tongue of the *Apteryx* is short; but short as it is, it is more developed than in other Struthious birds. The lining membrane of the *pharynx*, behind the *glottis*, forms two elongate, square-shaped, smooth, thick, and apparently glandular folds or processes, the obtuse free margins of which project backwards like lappels into the *pharynx*; beyond which the lining membrane is produced into close-set, narrow, somewhat wavy, longitudinal folds; the œsophagus is continued through the thorax and diaphragm to the proventriculus without forming any partial dilatation or crop. The *proventriculus* is a narrow elongated cylindrical cavity in the axis of the œsophagus, of which it is an immediate continuation. The gastric glands, narrow elongated follicles, are developed around its whole circumference, and are closely packed together; they are mostly bilobed, but sometimes more subdivided at their cæcal or outer extremities. The longitudinal rugæ of the lining membrane gradually subside at the entry of the proventriculus, where they run into each other, and so form a general reticulate surface, in the meshes of which the orifices of these glands are situated. The epithelium lining the glandular part of the stomach is gradually condensed towards its lower part into a cuticle, which, as it passes into the muscular compartment, assumes a brown colour and a callous hardness, and forms a stratum about one-third of a line thick. In the Cassowary and Emeu, observes Professor Owen in continuation, the proventriculus is marked off from the stomach by a circular strip of *epithelium*, whiter and thinner than the rest, from one to two lines in width, as is well shown in Sir Everard Home's *Comparative Anatomy* (pl. li., lii.). In this structure the Apteryx, though it resembles these species in the arrangement of the gastric glands, does not participate. Its muscular stomach does not present the characteristic subcompressed shape of a gizzard; but in its regular, oval, rounded form resembles the membranous stomach of carnivorous birds. It is small for the size of the bird in its contracted state; but when distended with food, Mr. Owen found that it measured 2½ inches in length, and two inches across at the widest parts. The muscular fibres are not *digastric* and *lateral*, as in the true gizzard; but, instead of being arranged in well-defined masses, radiate from two tendinous oval centres, measuring about two-thirds of an inch in the longest diameter. The pyloric passage is narrow, leading from the left side of the muscular stomach into the *duodenum*. A transverse crescentic ridge of the lining membrane defends the pylorus, but there is no distinct sphincter. The cuticle is continued into the duodenum about three lines beyond the pylorus, but the Professor found no dilatation of this part constituting a pyloric pouch, as in the Emeu and Ostrich. In one Apteryx there was a very short cæcum, the remnant of the ductus vitello-intestinalis, attached to about the middle of the small intestine, and from the same relative position of the intestinal tube in a small female specimen there extended an obliterated duct three lines long, which expanded into a still persistent subglobular vitelline sac, about an inch in diameter, but collapsed, and with wrinkled parietes. In a large male the intestinal canal measured four feet, independently of the cæca, each six inches in length: the rectum was four inches long. The lining membrane of the rectum, which is beset with minute short villi or points, together with glandulæ solitariæ, that become numerous and large at the terminal half of the rectum, is thrown, when it is contracted, into longitudinal folds; but there is no trace of the transverse or spiral valvulæ conniventes, characterising the cæca and rectum of the Ostrich and Rhea: and, in this respect, the Apteryx resembles the Cassowary and Emeu. The liver presented nothing extraordinary. In two of the specimens there was a gall-bladder, as in the Emeu and Cassowary; in the third it was wanting, as is usually the case in the Rhea and Ostrich. In the Apteryx without a gall-bladder there were two long ducts terminating in the same part of the duodenum. The *pancreas* consisted, as usual, of two elongated subtrihedral lobes; and the *spleen* was about the size and form of a hazel-nut.

Circulatory and Respiratory Systems.—In the same series of the museum above noticed, No. 923 exhibits the ventricles of the heart of an ostrich (*Struthio Camelus*) laid open to show the valves at the auricular and arterial orifices. In the right ventricle the auricular orifice is guarded by two valves, as in the crocodile; but the one on the right side is here much the largest, and both valves are muscular. A single artery, the pulmonic, arises from this ventricle, there being no vessel analagous to the visceral or left aorta of reptiles: its orifice is provided with three semilunar valves. The left auricular aperture is provided with two membranous valves, that on the right side of the orifice, which corresponds to the single valve of the crocodile, being the largest. The orifice of the aorta, which is situated directly behind that of the pulmonary artery, and, as it were, on the top of the septum, is provided with three semilunar valves. The muscular parietes of the ventricles are dense and compact; those of the left are of extraordinary thickness: the right ventricle is remarkable for the smoothness and evenness of its inner surface. No. 923 A is a transverse section of the ventricles of the heart of an American ostrich (*Rhea Americana*), showing the relative thickness of their muscular parietes, and their different form, the right appearing to be composed of a partial separation of some of the exterior fibres of the left ventricle. No. 923 B is the heart of an Emeu (*Dromaius Novæ Hollandiæ*) prepared chiefly to show the structure of the auricles. The veins of the body terminate, as in reptiles, by three principal trunks, which, with the coronary vein, unite to form a membranous sinus. Two fleshy semilunar valves are situated at the communication of the sinus with the auricle: they are fixed by their lower extremities to the floor of the auricle, but attached by the opposite ends to strong fleshy columns, which afterwards branch out into the musculi pectinati. The inferior valve is analogous to the Eustachian valve in the heart of Mammalia. The left superior cava opens into the sinus below the orifice of the inferior cava, and a small semilunar fold or valve intervenes between them. Whatever impediment therefore there may be to the free passage of the venous blood through the respiratory system, regurgitation from the auricle to the venous sinus is as carefully guarded against as in the Reptilia. The two pulmonary veins unite, and terminate in a single trunk in the left auricle: a large semilunar fold separates the muscular part of the auricle from the vein. The ventricles are laid open, showing on the right side the two fleshy valves, and on the left the two membranous valves placed at the auriculo-ventricular orifices. Of the great vessels arising from the heart, the left and most anterior is the pulmonary artery; the two next are the left and right *arteriæ innominatæ*, each giving off the carotid and subclavian of its corresponding side; the fourth vessel is the aorta, which winds over the right bronchus, like the right aorta in Reptilia. In the Ostrich the pulmonary cells of the lungs are of large size, as is shown in No. 1127 of the same series.

With reference to this part of the organization, we would call attention to Nos. 1155 and 1156 of that series, the first being a section of the trachea of an Ostrich, showing the rings narrow and entire, as in the rest of the birds, but retaining their cartilaginous texture. One of the longitudinal muscles of the trachea is left attached to this preparation. The second exhibits another section of the same trachea, from which the posterior part of the tube has been removed to show the thinness of the rings and the smoothness of the lining membrane. Both the lateral longitudinal muscles analogous to the *sterno-thyroidei* of Mammalia are preserved: these regulate the length of the air-tube, and accommodate it to the varied and extensive motions of the neck. (*Cat.*, vol. ii.)

In Apteryx the heart is surrounded by a wide and thin pericardium, which is attached to the concave side of the sternum and the margins of the anterior wide fissure of the diaphragm, through which the ventricular portion of the heart protrudes into the abdomen, in the posterior concave interspace of the two great lobes of the liver. Professor Owen remarks, that it requires only that a central *aponeurosis* should have been continued from the anterior margin of the diaphragm, between the heart and liver, to have completely separated from the thorax the proper abdominal

viscera, as in the Mammalia; for the respiratory organs are confined entirely to the thorax. The heart presents the usual ornithic form; but the right auricle appeared, when distended, of uncommon size. The three veins terminated in it in the usual manner; but the inferior cava has a much greater relative capacity than either of the superior cavæ, in consequence of these having to return to the heart little more than the proportion of venous blood brought back by the jugular and internal thoracic veins in other birds. There is no peculiarity of structure in the auricles of the heart; but the resemblance to the Emeu in the disposition of the valves of the right auricle is very close. The posterior valve, which forms part of the boundary of the foramen ovale, seems, Professor Owen observes, to be represented in Mammalia by the muscular ridge called the *annulus ovalis;* the anterior valve is obviously the analogue of the *Eustachian* in man and mammalia generally: the Professor found the principal deviation from the ornithic type of the structure of the heart in the valve at the entry into the right ventricle. This is characterised in birds, generally, by its muscularity and its free semilunar margin; but in the Apteryx it is relatively thinner, in some parts transparent and nearly membranous: a process moreover extends from the middle of its free margin, and is attached by two or three short *chordæ tendineæ* to the angle between the free and fixed *parietes* of the ventricle. In this mode of connection is perceived an approach to the mammalian type of structure analogous to that which the *Ornithorhynchus*, among mammalia, offers, in the structure of the same part to the birds; for, adds Professor Owen, the right auricular ventricular valve in the Ornithorhynchus is partly fleshy and partly membranous. In the left auricle, and in the valves between it and the left ventricle, there was nothing worthy of note; the two membranous flaps were unequal, presenting the usual characteristic of the mitral valve in birds. With regard to the *aorta*, the principal difference observed in the Apteryx was the equality of size in the carotids: in the Emeu, Professor Owen found the right carotid larger than the left. The descending or third primary division of the aorta presents, as in the Emeu and other Struthionidæ, more of the character of the continuation of the main trunk than in other birds, in consequence of its greater size and thicker tunics, relating to the diminished supply of blood transmitted to the rudimental anterior extremities, and the increased quantity required for the powerfully developed legs. 'The aorta,' continues the Professor, 'arches over the right bronchus as usual, and is continued down the thorax to the interspace of the crura of the diaphragm, through which it passes into the abdomen, in a manner remarkably analagous to that which characterises the course of the aorta in the Mammalia. The Apteryx, in fact, seems to be the only bird in which the limits of thoracic and abdominal aorta can be accurately defined; but, in thus establishing this distinction, we observe a remarkable difference from the mammalian arterial system, in the fact that some large and important branches, which in the latter are given off from the abdominal aorta, arise in the present bird above the diaphragm, through which they pass by distinct and proper apertures to the abdominal viscera, which they are destined to supply.'

Professor Owen did not observe any modification of that condition of the venous system which usually characterises the class of birds. The inferior cava did not perforate the diaphragm, but entered the posterior part of the pericardium just above the anterior fissure of the diaphragm, receiving close to its termination the two large hepatic veins. Professor Owen remarks that there exists the same disposition of the renal veins which regulates the quantity of blood transmitted to the lungs or the liver respectively, as in other birds; and that this disposition has been erroneously supposed to indicate that the urine was secreted from the venous blood in birds, as in reptiles and in fishes; but, he observes, the end attained by the venous anastomoses in question bears a much closer relation to the peculiar necessities and habit of life of the bird, and, so far as he knows, has not hitherto been explained.

There was not any trace of the extension of air-cells in the interspaces of the abdominal viscera; and Professor Owen was not less gratified than surprised to find *a complete and well-developed diaphragm* separating the abdominal from the respiratory cavity. This septum did not present any large openings corresponding to those by which the air is continued into the abdomen in the other struthious birds, but was here perforated only for the transmission of the œsophagus and large blood-vessels. 'The diaphragm of the Apteryx,' proceeds the Professor, 'differs from that which characterises the class Mammalia in the following points: first, in the greater relative extent of the anterior or post-sternal interspace; secondly, in the greater proportion of tendinous or aponeurotic tissue, which enters into its composition; thirdly, in being perforated by three different large arteries, and not by the vena cava or splanchnic nerves; and lastly, in the different relative positions of the œsophageal and aortic openings. The plane of the diaphragm is more horizontal, or rather, more parallel with the axis of the trunk, than in the Mammalia generally; but some of the aquatic species, as the *Dugong*, present a position of the diaphragm almost similar to that of the *Apteryx*. The origins of the vertebral or lumbar portion of the diaphragm are by two well-developed crura, which are attached to slight prominences on the sides of the last costal vertebra. These crura are almost entirely tendinous; they expand as they advance forwards, and distribute their aponeurotic fibres in a manner remarkably analogous to the disposition of the fleshy fibres of the lesser muscle of the diaphragm in Mammalia. The mesial fibres decussate in front of the aorta: the lateral ones arch outwards; the rest diverge to constitute the great central tendon. Here they cross each other in various directions, and form distinct and regular decussations around the orifices through which the cœliac artery, with the anterior splanchnic nerve, and the mesenteric artery and nerves, pass into the abdomen; the most noteable decussation is formed by two broad bands immediately behind the large œsophageal aperture, which is separated only by a very narrow transverse chord from the anterior fissure through which the pericardium protrudes and the inferior vena cava passes, the two broad decussating bands expand to form the anterior boundary of the diaphragm, and are inserted into the lateral processes of the sternum. The muscular or costal part of the diaphragm is formed, as in the Ostrich, by a number of separate, broad, and thin fasciculi, which come off from the third, fourth, fifth, sixth, and seventh vertebral ribs, near their junction with the sternal ones. These fasciculi expand, and are gradually lost upon the dorsal surface of the aponeurotic part of the diaphragm, but do not form a conspicuous expanse of muscle, nor constitute the entire thickness or substance of the diaphragm at any point. They are consequently invisible on the abdominal side of the diaphragm, and the aponeurosis of the diaphragm, together with the almost aponeurotic cellular layer of the peritoneum, with which it is continuous, requires to be reflected inwards to bring the digitations representing the great muscle of the diaphragm into view.'

Professor Owen, after adverting to the long recognised existence of a diaphragm in a rudimental condition in birds, and Hunter's beautiful figure of the costal portion of that of the Ostrich (*Cat. Mus. Coll. Chir.*, vol. ii., pl. xxvi., *Physiol. Series*), observes that in this, as well as in the other large Struthious birds, there is also a *pars vertebralis*, or analogue of the lesser muscle of the diaphragm, which rises by two tendinous crura from the last dorsal vertebra, and in the Emeu, by a double origin on each side. Nevertheless, he remarks, their diaphragm is incomplete; first, by reason of an arrest of its centripetal development, which leaves a permanent defect of union in the mesial plane; and, secondly, by the large perforations for the abdominal air-cells.

Professor Owen found the mechanism of respiration in the *Apteryx* essentially the same as in other birds, and he states that a more muscular diaphragm than it possesses would be unnecessary as a part of the mechanism. As in the Mammalia, the abdominal surface of the diaphragm is principally in contact with the liver, spleen, and stomach, but its thoracic surface does not support the heart, and it is separated from the lungs by the interposition of a series of small but well-marked air-cells. No thoracic serous sac or pleura could be traced. 'Thus,' says Professor Owen, 'although the respiratory organs are confined to the chest, and the Apteryx offers the only known instance in the feathered race of a species in which the receptacular part of the lungs is not continued into the abdomen, yet the Struthious type is strictly preserved, and the march of development has only been restricted, not changed.'

Brain, Nervous System, and Senses.—The brain and nervous system appear to be, generally speaking, well developed in the Struthious birds. No. 1322 and No. 1323

in the Physiological Series of the *Mus. Coll. Chir.*, exhibit the brain of an Ostrich minutely injected, and the section of the cerebellum removed from the brain. Nos. 1352 to 1357, both inclusive, are preparations of the spinal chord of the same bird. The original description of No. 1355, which shows the sacral and caudal portions, is as follows:—'The part of the medulla which lies in the loins and tail of an Ostrich. That part which lies in the loins is considerably larger than those which belonged to the neck and back: and then it becomes pretty fast smaller to the tail. This swelling in the loins is owing perhaps to this bird having such large thighs and legs: and when we consider that this bird, having such small wings, must have the whole progressive motion performed by the legs, and the legs are therefore longer in proportion to the size of the bird than in birds in common, we must see why the medulla ought to be large at this part in this bird.'

Touch.—No. 1401 of the same series is a strip of cutis from the foot of the Ostrich, showing the papillæ or coarse villi on that part: they are very closely set, and about a quarter of an inch in length, placed parallel to one another, and perpendicular to the surface which is applied to the soil in walking.

Taste tolerably well developed. Nos. 1474 to 1476, both inclusive, show the tongue, &c. of certain Struthionidæ. The two first exhibit those parts in the Ostrich; No. 1475 is the tongue, os hyoides, and larynx of a Rhea, in which bird the tongue is relatively larger than in the Ostrich, which has that organ of so small a size that it has been taken for an epiglottis. The tongue of the Rhea is studded over with minute black specks, which are the orifices of muciparous glands. In No. 1476, showing the same parts in a Cassowary (*Cassuarius galeatus*), the tongue is seen to be thin, flat, and serrate on the edges.

Smell.—The olfactory system is well developed in the Struthionidæ. In the Apteryx it appears to be altogether larger than in other birds. Professor Owen observes that the nocturnal habits of the Apteryx, combined with the necessity for a highly developed organ of smell, which chiefly compensates for the low condition of the organ of vision, produce the most singular modifications which the skull presents, and, he adds, that we may say that those cavities which in other birds are devoted to the lodgement of the eyes, are, in the Apteryx, almost exclusively occupied by the nose.

Sight.—The eye is well formed, and the sight piercing in the Struthionidæ generally; but, in the Apteryx, the eye has less development than appears in the rest of the family, the reasons for which are above assigned. It presents a remarkable deviation from the construction characteristic of birds generally, in the total absence of the *pecten* or *marsupium*, a privation compatible with the nocturnal habits and restricted locomotion of this species. 'The eyeball,' says Professor Owen, 'is relatively much smaller than in other birds; its antero-posterior diameter is three lines; its transverse diameter four lines. The cornea transparens is very convex, and two lines in diameter. The sclerotic is thin, but the margin supporting the cornea is strengthened by a circle of small osseous plates. The choroid is a delicate membrane; its pigment is of a light brown colour. The ciliary processes commence at the ciliary ring, each process having at its origin a slight linear rising, which becomes gradually wavy and tortuous as it approaches the lens, anterior to the circumference of which it projects freely to a small extent. The iris in the specimen examined was one-third of a line in breadth. The optic nerve terminates by a small round aperture. The lens is two lines in breadth, and nearly one line at the thickest part, being thus more convex than in other birds. The external appendages of the eye presented no peculiarities, except the very great strength of the orbicularis palpebrarum: the membrana nictitans had the usual trochlear muscles: its free margin was black.'

Hearing.—This sense appears to exist in considerable perfection in the Struthious birds.

Renal and Genital System.—No. 1195 of the Physiological Series in the museum of the Royal College of Surgeons presents the kidneys of an ostrich, of an elongated flattened form and lobulated, but with the divisions not extending so deeply into the glandular substance as in most other birds: the anterior lobe, which is the largest, is nevertheless completely separated from the rest. The substance of the different lobes has a convoluted disposition like that of the reptiles, but is more compact. The renal arteries sent off from the aorta are shown on one side, and the corresponding veins joining the inferior cava on the opposite, where also the testes and supra-renal glands are seen: bristles are placed in the ureters. No. 2456 shows the testicles of a cassowary (*Cassuarius galeatus*) of a more elongated form than in the fowl. They are relatively small, the bird having died before the season of sexual excitement. No. 2468 is the penis of an Emeu (*Dromaius Nov. Holl.*), resembling in structure that of the anserine birds: the elastic ligamentous substance which enters into its composition is also disposed so as to retract it into a spiral figure. 2469 is the penis of an Ostrich injected, showing the two fibro-cartilaginous substances, commencing by separate crura, and forming the principal part of the body of the penis, between which and along the upper surface of the penis is continued the groove representing the urethra; the true corpus cavernosum is situated on each side of this groove; the part which is reflected back from the extremity of the penis, and seems to represent the glans, consists of the elastic ligament which effects the retraction of the penis. At the commencement of the urethral groove the papillæ are preserved, on which the vasa deferentia terminate: bristles are passed through these papillæ. No. 2470 is a transverse section of the injected corpus cavernosum from the same penis. The Ostrich from which the present and preceding preparation were taken stood eleven feet high. (*Cat. Mus. Coll. Chir.*) The penis is exposed and the groove exhibited when the bird discharges its urine. No. 2734 shows the cloaca and termination of the oviduct, ureters, and rectum, with the urinary bladder and clitoris of an Ostrich. (*Catalogue.*)

The kidneys of the Apteryx are situated symmetrically, and lodged, as in other birds, in the irregular hollows of the back part of the cavity of the pelvis. Each kidney is divided into five lobes by oblique fissures extending into the posterior surface of the gland: the middle lobe is the largest. The lobes appear to have a compact and even surface, but their cerebriform convolutions can, Professor Owen states, be readily unravelled. The tortuous ureter emerges from the inner side of the posterior extremity of the kidney, and, after a course of an inch and a half, terminates in the upper and back part of the uro-genital cavity. The oval and yellow supra-renal bodies were of homogeneous texture, each three lines in length, and adhering closely to the vena cava. The testes were of a subcompressed oval figure. The vasa deferentia are formed by the union of numerous most minute efferent tubules, which pass from the testes, without forming an epididymis, into a soft amorphous substance of a grey colour, which lies between the testes and the bright yellow supra-renal body. The vas deferens formed by the greater part of the tubules perforates the corpus Wolffianum. The penis, which projects from below the external orifice of the urethro-sexual cavity into the vestibular or outer compartment of the cloaca, rapidly diminishes to a point, and its extremity is spirally retracted. An urethral or rather seminal groove traverses the upper, or what, if the penis were drawn out of the cloaca and bent forwards along the abdomen, would be its under surface, and is continued to the end of its spiral extremity: the margins of the groove are not beset with papillæ, but simply wrinkled transversely, as in the Emeu and Ostrich. Immediately above the base of the penis there is, on each side, a considerable plexus of arteries and veins, over the base of which plexus muscles cross, which would, Professor Owen thinks, impede, if not arrest, the current of the blood in the veins, and he observes that they might be termed *compressores venarum penis*, as they fulfil the same office as the *compressores* described by Douglas in the dog. Nothing deserving particular remark appears to have been observed in the female organs, though the careful statement of the detail in Professor Owen's paper well deserves the student's attention.

The myology of *Apteryx* by that author is now before the Zoological Society of London, and we understand that the neurology of the bird by the same hand is also to be laid before that Society.

Systematic Arrangement and Natural History.

The place assigned to the Struthious birds by zoologists generally will be found in the articles Birds and Grallæ. Mr. Vigors observes that those species of Tetraonidæ which exhibit a weakness or a deficiency in the hinder toe lead us at once to the three-toed groups of the *Struthionidæ*,

with the bills of which, more particularly that of *Rhea*, those of some species of *Tinamus* correspond. Mr. Vigors includes in the family the *Brevipennes* of Cuvier, together with the genus *Otis* [BUSTARD] of Linnæus, which Mr. Vigors observes evidently agrees with them in their principal characters. It corresponds also, he adds, with the order *Cursores* of Temminck, with the exception of the genus *Cursorius*, Lath., which, he thinks, possesses more of the characters of the *Wading* than of the *Gallinaceous* order; but with which, he remarks, the present family will still be found to preserve its affinity by means of the circular disposition which, he conceives, is seen to prevail throughout the divisions of ornithology. The chief genera comprised in the *Struthionidæ* are the *Rhea*, which, in Mr. Vigors's opinion, unites this family with the last; *Struthio*, Linn., which having but two toes, and thus carrying the character of the group to the extreme, may be considered the type; *Casuarius*, Brisson; *Dromiceius*, Vieill.; *Otis*, Linn.; and *Didus*, supposed to be extinct. [DODO.] In this arrangement the *Struthionidæ* stand between the *Tetraonidæ* and the *Cracidæ* in the order RASORES. *Apteryx* was not sufficiently known when Mr. Vigors wrote. Mr. Swainson arranges the family in the same order between the *Tetraonidæ* and the COLUMBIDÆ, and he comprises under the *Struthionidæ* the genera *Otis* and *Struthio*, the latter comprehending the subgenera *Casuarius*, *Dromiceius*, *Apternyx* (Apteryx), and *Rhea*. From this family Mr. Swainson entirely excludes the *Dodo*, which was, in his opinion, the rasorial type of the *Vulturidæ*.

Mr. G. R. Gray makes the *Struthionidæ* the first family of the order *Cursores*, Temm., the sixth order in Mr. Gray's arrangement, and includes under it the following subfamilies and genera:—

Subfam. 1. Struthioninæ.

Genera.—*Struthio*, Linn.; *Casuarius*, Briss.; *Dromaius*, Vieill.; and *Rhea*, Briss.

Subfam. 2. Apteryginæ.

Genus.—*Apteryx*, Shaw.

? Subfam. 3. Didinæ.

Genus.—*Didus*, Linn.

Subfam. 4. Otinæ.

Genera.—*Otis*, Linn.; *Tetrax*, Leach; *Sypheotides*, Less.; *Chlamydotis*, Less.; and *Eupodotis*, Less.

The *Struthionidæ* are placed in Mr. Gray's arrangement between the *Tinamidæ*, the last family of his *Rasores*, and the *Charadriadæ* [PLOVERS], the first family of his *Grallatores*.

Amongst the *Mammalia* the MARSUPIALIA make the nearest approximation to the *Ovipara*; and amongst the birds the *Struthionidæ* approach the most closely to the *Mammals* and the *Reptiles*.

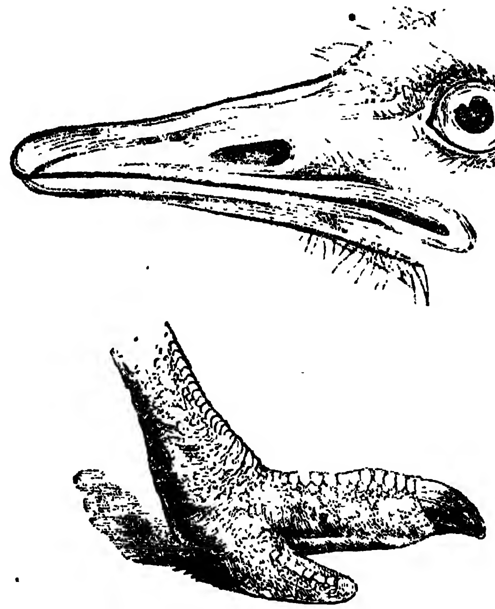
This approximation of the Struthious birds to the *Mammalia* especially cannot fail to strike the physiologist. In the first and typical genus, *Struthio*, it is strongly manifested.

STRUTHIONIDÆ OF THE OLD WORLD.

Struthio. (Linn.)

Generic Character.—*Bill* moderate, obtuse, straight, depressed at the point, which is rounded and unguiculate; mandibles equal and flexible; nasal fossæ longitudinal, prolonged half way down the bill, open. *Feet* very robust; toes two only, stout and strong, directed forwards, and connected at their base by a strong membrane, the internal toe considerably larger than the external, and furnished with a thick and hoof-like claw, external toe clawless. Wings useless for flight, furnished with long soft undulating plumes, and armed with two spurs, or rather two plumeless shafts, not unlike a porcupine's quill. *Head* and upper half of the neck scantily covered with a thin down, through which the colour of the skin is visible.

It would be a needless occupation of space to give a minute description, which is so well known in these days of zoological societies and menageries. The Ostrich is generally understood to be the bird designated by the terms *Jonah* or *Jaanah* and *Rinonim*, in the Scriptures (*Levit.*, xi. 19; *Deut.*, xiv. 15; *Job*, xxx. 29; *Isai.*, xiii. 21; xxxiv. 13; xliii. 20; *Jer.*, l. 39; *Lament.*, iv. 3; *Mic.*, i. 8; *Job*, xxxix. 13). In many of these passages, *Jer.*, l. 39, and *Isai.*, for instance, our version reads 'Owls,' and in *Levit.* does not mention the Ostrich, but the general opinion seems to be in favour of the Ostrich being intended. It is the *Neamah* of the Arabs, *Thar edsjammel* (Camel-bird) of the Orientals, Στρουθοκάμηλος (Struthocamelos) of the Greeks, *Struthiocamelus* of Pliny and the antient Italians, *Struzzo* and *Struzzolo* of the modern Italians, *Strauss* of the Germans, *Autruche* of the French, and *Struthio Camelus* of Linnæus.



Head and Foot of Ostrich.

Food, Habits, &c.—The approximation in the digestive organs of the ostrich to the structure of some of these parts in the Ruminantia, especially in the additional ventricle of the bird, is still further strengthened by the bisulcous foot, which may not be inaptly compared to that of the camel, and probably led in no small degree to its appellation of Camel-Bird, to which, moreover, its height, lengthened neck, habit of frequenting the desert, and patience under thirst may have contributed.

The food of the ostrich consists of vegetable substances only, but seeds and grain appear to be preferred, and it is consequently a most unwelcome neighbour to the cultivator of the soil, on whose crops the bird commits great devastation. Its iron-eating propensities have long been celebrated, and indeed it picks up and swallows any mineral substance, metallic or not, with indiscriminating voracity. Nor is this propensity confined to the devouring of minerals; for leather, hair, cordage, and wood do not seem to come amiss. In the stomach of one of those birds Valisnieri found a farrago of grass, nuts, cords, stones, glass, brass, iron, tin, copper, lead, wood, and among the stones one weighing more than a pound.

Perrault took from an ostrich's stomach seventy *doubles*, the greater part of which were worn down three-fourths of their substance by collision against each other or the pebbles found with them: those which were bent were worn and polished on the convex side, while they remained entire on the concave surface. These copper pieces had tinged everything in the stomach with green. This eagerness for picking up everything, whether or not it can be assimilated or can assist in the grinding down of the food by the action of the stomach, to which no doubt the polishing and wasting of the pieces of money mentioned by Perrault were due, is often fatal to the ostrich. Too great a quantity of copper or iron thus taken into the stomach has caused the death of the bird. Valisnieri saw one killed by swallowing a quantity of quick-lime; and one kept in the Gardens of the Zoological Society of London was first deformed and afterwards died from swallowing part of a parasol. Some of the heterogeneous contents found in the stomachs of these birds are preserved in the Museum of the Royal College of Surgeons (*ante*, p. 137).[1]

Their speed is great. The swiftest greyhound cannot overtake them; and even the Arabian and his horse are obliged to have recourse to cunning as well as speed to close the chase, by throwing a stick dexterously between its legs, or otherwise to disable it. In its flight it spurns the pebbles behind it like shot against the pursuer. Nor is this its only mode of annoyance. Dr. Shaw, who gives a pretty

account of the airs which the ostrich plays off in a domesticated state, fanning itself with its expanded wings, and seeming to admire its own shadow, states, that though tame and tractable to those familiar with them, these birds were often very fierce to strangers, especially those of the poorer sort, whom they would try to run down and attack with their feet. They are capable of striking with great force, and the same author gives a melancholy account of a person whose belly was ripped up by a stroke from the pointed and angular claw. The European sportsman, after riding so that the bird shall pass within shot, dismounts and brings it down with the rifle.

The strength of the ostrich is great. Adanson mentions the rapidity with which a large tame one ran, first under the weight of two little blacks, and afterwards under two full-grown negroes, while a smaller bird carried with equal facility one full-grown negro.

The general opinion is that the ostrich is not polygamous: *quære tamen.* The number of eggs does not seem to be correctly ascertained. From twenty to thirty, and thirty-eight with thirteen others scattered around the inartificial nest—a mere pit in the sand, which is thrown up so as to form an elevated edge round it, about three feet in diameter—have been found together. Some have made the number eighty; others reduce it to ten. This is the number that Le Vaillant would assign to a single female, although he disturbed one from the nest containing the thirty-eight eggs surrounded by the thirteen others. This nest he watched, and saw during the day four females successively sit upon them; and towards the close of the evening a male took his turn of incubation. This then was probably a common nest in which several females had laid their eggs.

The passage in *Job* (xxxix. 14) will occur to every one, and there is no doubt that within the torrid zone the heat of the sun's rays renders the incubation of the female unnecessary, excepting perhaps at night; but in cooler latitudes she performs the maternal office with assiduity, and even in the warmer climates, where an officious determination to sit would in all probability endanger the vitality of the eggs, she watches over them; and indeed the hunters have learned from her actions, and doubling back in her flight to one particular spot, where to seek for the nest. If, as has been asserted, the outlying eggs are intended to serve for the nourishment of the young, it is a proof of provident care for her offspring on the part of the mother.

Utility to Man.—The flesh of the ostrich when young is good and palatable, and the eggs are considered a great delicacy. Both Europeans and natives agree in this last opinion. The Hottentot, who abstracts the egg from the nest with a long stick, that the hen may not take alarm at the human touch, and not abandon the nest, but go on laying, as the common hen will do to a great extent when her nest is robbed, buries them in hot ashes. They are said to be excellent when eaten with a sufficient quantity of butter. The brains of hundreds of these birds not unfrequently made a dish at the insane Roman suppers; and Firmius is said to have eaten a whole ostrich at a meal. The flesh of the bird was prohibited by the Mosaical law as unclean, and the Arabs regard it in the same light; but many of the barbarous tribes of the interior of Africa feed on it without scruple. The well-known plumes form a material article of commerce for the head-dress of European ladies, &c.

There is in the noble and admirably arranged zoological gallery of the British Museum a fine and well-preserved series of young ostriches. Not the slightest trace of a nail is observable on the external toe of any of them, any more than on that of the adult bird. The usual height of the ostrich is from seven to eight feet, but it has reached to eleven feet (*ante*, p. 140).

Geographical Distribution.—Africa. Scarcely known beyond the limits of the Arabian deserts.

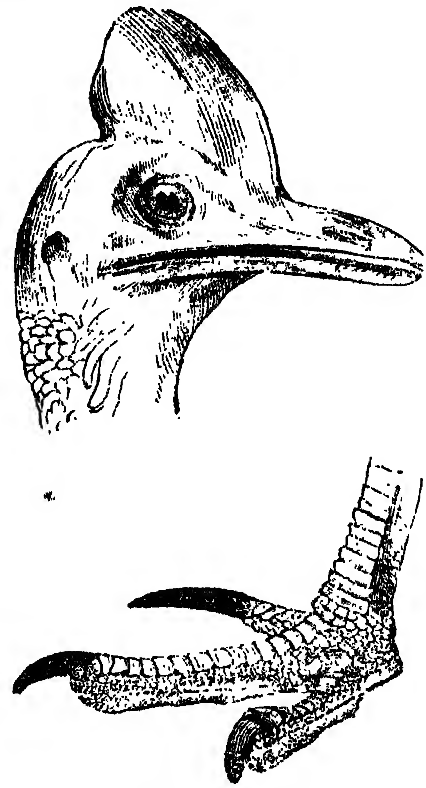
Casuarius. (Briss.)

Generic Character.—*Bill* straight, carinated above, rounded and bent at the point; upper mandible slightly vaulted, the edges depressed, and notched or jagged towards the extremity; the lower mandible rather angular below towards the point; nasal fossæ nearly as long as the bill. *Head* helmeted. Front of the *neck* naked, and furnished with two wattles. *Toes* three. Wings entirely unfit for flight, furnished with five round naked pointed quills.

Example. *Casuarius Emeu.*

Description.—Bill compressed laterally, the head surmounted with a bony prominence covered with a horny substance; skin of the head and the upper part of the neck naked, tinged with cerulean blue and flame-colour, with pendent wattles like those of a turkey-cock; wings furnished with some stiff featherless quills; nail of the internal toe much the strongest. 'It is,' says Cuvier in continuation, 'the largest of the birds after the ostrich,* from which it differs sufficiently in its anatomy, for it has short intestines and small cæca, wants the intermediate stomach between the crop and the gizzard, and its cloaca does not exceed that of other birds in proportion.

This well-known bird was named *Emeu* by the early Portuguese navigators. It is the *Emeu* vulgo *Casoaris* (the latter appearing to be the Malayan appellation) of Bontius, the *Struthio Casuarius* of Linnæus, *Casuarius galeatus* of Vieillot, and *Cassowary* of the British naturalists, who now apply the term *Emeu* to the New Holland Cassowary (Dromaius, Vieill.). Its height when erect is about five feet.



Head and Foot of Cassowary.

Geographical Distribution.—The peninsula of Malacca and the great chain of islands to the south and east. Bontius notes it from Ceram and the other neighbouring Molucca Islands. M. Lesson observes that it is very common in the islands of the Asiatic Archipelago, and especially at New Guinea. It is frequently seen alive in our menageries, and is common in museums.

Food, Habits, &c.—This species, which is characterised by M. Lesson as 'stupid and massive,' feeds on seeds and herbage according to him; but Cuvier says that it eats fruits and eggs, but no grain. Bontius states that he does not think it should be placed among the birds: 'Alæ enim ad currendum pro velo, non ad velandum inserviunt.' He adds, that when irritated, it does not rush forward to the attack, but turns itself obliquely, kicking backwards at the enemy. Cuvier observes that the featherless quills serve the bird for offensive weapons. Bontius remarks that the eggs are very different from those of the ostrich, by reason of their thinness and colour, for their shell is greenish, ornamented with numerous tubercles of a deeper green (saturè viridibus): he adds that they are eaten by the natives. Cuvier relates that the bird lays a small number of green eggs, which it abandons, like the ostrich, to the heat of the climate.

Didus. [Dodo.]

By the kindness of Professor Owen, we are enabled to give the following interesting additions to the evidences of the existence of this interesting form:—

* But see post, p. 145.

'Whilst at the Hague,' writes the Professor to Mr. Broderip, 'in the summer of 1838, I was much struck with the minuteness and accuracy with which the exotic species of animals had been painted by Savery and Breughel in such subjects as Paradise, Orpheus charming the Beasts, &c., in which scope was allowed for grouping together a great variety of animals. Understanding that the celebrated menagerie of Prince Maurice had afforded the living models to these artists, I sat down one day before Savery's Orpheus and the Beasts, to make a list of the species which the picture sufficiently evinced that the artist had had the opportunity to study alive. Judge of my surprise and pleasure in detecting in a dark corner of the picture (which is badly hung between two windows) the *Dodo*, beautifully finished, showing for example, though but three inches long, the auricular circle of feathers, the scutation of the tarsi, and the loose structure of the caudal plumes. In the number and proportions of the toes, and in general form, it accords with Edwards's oil painting in the British Museum; and I conclude that the miniature must have been copied from the study of a living bird, which it is most probable formed part of the Mauritian menagerie.

'The bird is standing in profile, with a lizard at its feet. Not any of the Dutch naturalists to whom I applied for information respecting the picture, the artist, and his subjects, seemed to be aware of the existence of this evidence of the Dodo in the Hague collection.

'I think I told you that my friend Professor Eschricht of Copenhagen had written to inform me that the *skull of a Dodo* had been lately discovered in the museum at Copenhagen: it had before formed part of the museum of the Duke of Gottorp.'

American Struthionidæ.

Rhea. (Briss.)

Generic Character.—*Bill* straight, short, rather soft, furnished at its base with an obliterated membrane, slightly depressed, moderate, the point rounded, beak and unguiculated; upper mandible with its back elevated, notched towards the end; lower mandible flat below; nostrils large, longitudinal. *Wings* improper for flight, the phalanges furnished with plumes and terminated by a spur. *Head* completely feathered. *Feet* three-toed, all the toes furnished with claws.

Foot of Rhea.

In this genus the wing is better developed than in any of the Struthious birds, but it is still useless as an organ of flight.

Till lately the only species known was *Rhea Americana*, the *Nhandu-Guaçu* of the Brazilians. (Marcgrave: Piso.) It is described as haunting the banks of rivers and having the same propensity for swallowing iron and stones as the African ostrich, running so swiftly and cunningly, aided by its wings, as not only to evade the pursuit of dogs, but the weapons of the barbarians. The females are said to lay eggs like other ostriches, but smaller, in the sand; and it is added that the males sedulously perform the function of incubation: 'Salaces sunt admodum, mentulamque aliquantum aduncam vibrant sæpe, donec reperta femella eam rigidissimè ineant, suppressamque diu immobilem teneant.' (Piso.) The same author states that these American ostriches are fond of flesh, the best fruits, and the little fishes washed to the bank; nor do they spare the grey amber, if they can gain possession of it on the shore. He adds that their flesh is approved of and solid, equalling that of our swans and geese.

This American ostrich is the *Struthio Rhea* of Linnæus, the *Tuiju* of Lacépède; but we owe the perfect knowledge of a second species to Mr. Darwin, who has given a figure and ample descriptions of the bird and its habits in the 'Zoology of the Beagle,' and in his 'Researches in Zoology and Natural History;' but before we proceed to notice *Rhea Darwinii*, we must give his valuable account of the habits of *Rhea Americana*.

'This bird,' says Mr. Darwin, 'is well known to abound on the plains of La Plata. To the north it is found, according to Azara, in Paraguay, where however it is not common; to the south its limit appears to be from 42° to 43°. It has not crossed the Cordillera; but I have seen it within the first range of mountains on the Uspallata plain, elevated between six and seven thousand feet. The ordinary habits of the ostrich are well known. They feed on vegetable matter, such as roots and grass; but at Bahia Blanca I have repeatedly seen three or four come down at low-water to the extensive mud-banks, which are then dry, for the sake, as the Gauchos say, of catching small fish. Although the ostrich in its habits is so shy, wary, and solitary, and although so fleet in its pace, it falls a prey, without much difficulty, to the Indian or Gaucho armed with the bolas. When several horsemen appear in a semicircle, it becomes confounded, and does not know which way to escape. They generally prefer running against the wind; yet at the first start they expand their wings, and, like a vessel, make all sail. On one fine hot day I saw several ostriches enter a bed of tall rushes, where they squatted concealed till quite closely approached. It is not generally known that ostriches readily take to the water. Mr. King informs me that in Patagonia, at the bay of St. Blas and at Port Valdes, he saw these birds swimming several times from island to island. They ran into the water, both when driven down to a point, and likewise of their own accord, when not frightened: the distance crossed was about two hundred yards. When swimming, very little of their bodies appears above water, and their necks are extended a little forward: their progress is slow. On two occasions I saw some ostriches swimming across the Santa Cruz river, where it was about four hundred yards wide, and the stream rapid.

'The inhabitants who live in the country readily distinguish, even at a distance, the male bird from the female. The former is larger and darker coloured, and has a longer head. The ostrich, I believe the cock, emits a singular deep-toned hissing note. When first I heard it, standing in the midst of some sand-hillocks, I thought it was made by some wild beast, for it is a sound that one cannot tell whence it comes or from how far distant. When we were at Bahia Blanca in the months of September and October, the eggs were found, in extraordinary numbers, all over the country. They either lie scattered single, in which case they are never hatched, and are called by the Spaniards huachos, or they are collected together into a shallow excavation which forms the nest. Out of the four nests which I saw, three contained twenty-two eggs each, and the fourth twenty-seven. In one day's hunting on horseback, sixty-four eggs were found; forty-four of these were in two nests, and the remaining twenty scattered huachos. The Gauchos unanimously affirm, and there is no reason to doubt their statement, that the male bird alone hatches the eggs, and for some time afterwards accompanies the young. The cock when on the nest lies very close; I have myself almost ridden over one. It is asserted that at such times they are occasionally fierce, and even dangerous, and that they have been known to attack a man on horseback, trying to kick and leap on him. My informer pointed out to me an old man, whom he had seen much terrified by one chasing him.'

Mr. Darwin, after having referred to the passage in Burchell's 'Travels in South Africa,' in which that traveller remarks, that having killed a male ostrich with dirty feathers, it was said by the Hottentots to be a nest bird, and referring to the male emu's habit of taking care of the nest, proceeds as follows:—

'The Gauchos unanimously affirm that several females lay in one nest. I have been positively told that four or five hen birds have been actually watched and seen to go, in the middle of the day, one after the other, to the same nest. Although this habit at first appears very strange, I think the cause may be explained in a simple manner. The number of eggs in the nest varies from twenty to forty, and even to fifty; and, according to Azara, seventy or eighty. Now, although it is most probable, from the number of eggs found in one district being so extraordinarily great in proportion to that of the parent birds, and

likewise from the state of the ovarium of the hen, that she may in the course of the season lay a great number, yet the time required must be very long. Azara states that a female, in a state of domestication, laid seventeen eggs, each at the interval of three days, one from another. If the hen were obliged to hatch her own eggs, before the last was laid the first probably would be addled; but if hens, as is stated to be the case, combined together, then the eggs in one collection would be nearly of the same age. If the number of eggs in one of these nests is, as I believe, not greater, on an average, than the number laid by one female in the season, then there must be as many nests as females, and each cock-bird will have its fair share of incubation; and this during a period when the females probably could not sit, on account of not having finished laying.* I have before mentioned the great numbers of huachos, or scattered eggs; so that in one day's hunting the third part found were in this state. It appears odd that so many should be wasted. Does it not arise from some difficulty in several females associating together, and in finding a male ready to undertake the office of incubation? It is evident that there must at first be some degree of association between at least two females, otherwise the eggs would remain scattered at distances far too great to allow of the male collecting them into one nest. Some authors believe that the scattered eggs are deposited for the young birds to feed on. This can hardly be the case in America, because the huachos, although often addled and putrid, are generally whole.'

Variety of Rhea Americana.—It would appear that there is a white or albino variety of this species, for a Gaucho told Mr. Darwin that he had once seen a snow-white one, and that it was a most beautiful bird.

Rhea Darwinii was described by Mr. Gould, at a meeting of the Zoological Society of London. It is smaller, and the general tinge of the plumage is light-brown in place of grey; each feather being conspicuously tipped with white. The bill is considerably smaller, and, especially, less broad at its base; the culmen is less than half as wide, and becomes slightly broader towards the apex, whereas in the *R. Americana* it becomes slightly narrower: the extremity of both the upper and the lower mandible is more tumid in the latter than in *R. Darwinii*, and there are other differences.

Rhea Da

The first notice Mr. Darwin received of this species was at the Rio Negro, in Northern Patagonia, where he repeatedly heard the Gauchos talking of a very rare bird, called *Avestruz Petise*. They described it as being less than their common ostrich, which is there abundant, and with differences of colour, and said that it was more easily caught by the bolas than the other species. The eggs of the small species appeared more generally known, and it was remarked, with surprise, that they were very little less than those of the common *Rhea*, but of a slightly distinct form, and with a tinge of pale blue. Some eggs that Mr. Darwin picked up on the plains of Patagonia agreed pretty well with this description, and he doubted not that they were those of the *Petise*. He states that this species occurs most rarely in the neighbourhood of the Rio Negro; but that about a degree and a half farther south they are tolerably abundant. One Gaucho however told him that he recollected having seen one, many years before, near the mouth of the Rio Colorado, which is north of the Rio Negro. They are said to prefer the plains near the sea. Mr. Darwin goes on to state, that when at Port Desire, in Patagonia (lat. 48°), Mr. Martens shot an ostrich. Mr. Darwin looked at it, and forgetting at the moment the subject of the Petises, thought it was a two-third grown one of the common sort. The bird was skinned and cooked before Mr. Darwin's memory returned: but the head, neck, legs, wings, many of the larger feathers, and a large part of the skin had been preserved. This constitutes the specimen in the museum of the Zoological Society.

'Among the Patagonian Indians in the Strait of Magellan,' says Mr. Darwin in continuation, 'we found a half-bred Indian, who had lived some years with this tribe, but had been born in the northern provinces. I asked him if he had ever heard of the Avestruz Petise. He answered by saying, 'Why there are none others in these southern countries.' He informed me that the number of eggs in the nest of the Petise is considerably less than with the other kind, namely, not more than fifteen on an average; but he asserted that more than one female deposited them. At Santa Cruz we saw several of these birds. They were exceedingly wary: I think they could see a person approaching, when he was so far off as not to distinguish an ostrich. In ascending the river, few were seen; but in our quiet and rapid descent, many, in pairs, and by fours or fives, were observed. It was remarked by some of the officers, and I think with truth, that this bird did not expand its wings, when first starting at full speed, after the manner of the northern kind. The fact of these ostriches swimming across the river has been mentioned.'

In conclusion, Mr. Darwin remarks, that *R. Americana* inhabits the eastern plains of South America as far as a little south of the Rio Negro (lat. 41°), and that *R. Darwinii* takes its place in Southern Patagonia; the part about Rio Negro being neutral ground.

We have said that we owe the perfect knowledge of this smaller species to Mr. Darwin. There is no doubt that others have seen it. Dobrizhoffer (1749) clearly was aware of its existence. In his account of the Abipones, he says, 'You must know moreover that Emus differ in size and habits in different tracts of land; for those that inhabit the plains of Buenos Ayres and Tucuman are larger, and have black, white, and grey feathers; those near to the Strait of Magellan are smaller and more beautiful, for their white feathers are tipped with black at the extremity, and their black ones in like manner terminate in white.' Those ostriches which Wallis saw at Batchelor's river (lat. 53° 54′) in the Strait of Magalhaens, were doubtless Petises. Mr. Darwin notices these instances, and further remarks that the distinguished French naturalist M. A. D'Orbigny, when at Rio Janeiro, made great exertions to procure this bird, but did not succeed. 'He mentions it,' says Mr. Darwin, 'in his "Travels" (vol. ii., p. 76), and proposes (in case, I presume, of his obtaining a specimen at some future time, and thus being able to characterize it) to call it *Rhea pennata*.' Now Mr. Gould has characterized it from the specimen brought home by Mr. Darwin (1837), who liberally presented his valuable zoological collection to the Zoological Society of London, and has given the interesting account of its habits and geographical distribution above quoted. Mr. Gould's name therefore must have the preference.

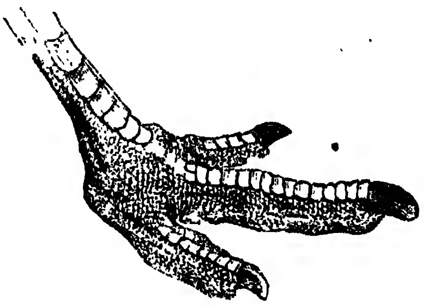
* Lichtenstein however ('Travels,' vol. ii., p. 25) states that the hens begin to sit when ten or twelve eggs are laid, and that they afterwards continue laying. He affirms that by day the hens take turns in sitting, but the cock sits all night.

Rhea Americana has been exhibited alive in the Gardens of the Zoological Society of London, and specimens of both species are, we believe, to be seen in the museum of that Society and in the British Museum.

AUSTRALIAN AND NEW ZEALAND STRUTHIONIDÆ.

DROMAIUS. (Vieill.)

Generic Character.—*Bill* straight, with the edges very much depressed, rounded at the extremity, slightly carinated above. *Nostrils* large, protected by a membrane and opening above about the middle of the bill. *Head* feathered. *Throat* nearly naked. *Feet* three-toed



Foot of Emeu.

This is also the genus *Dromiceius* of Vieillot, *Tachea*, Flem., and the form is placed by Latham under the genus *Casuarius*, and by Temminck under *Rhea*.

The *Emeu, Emu*, or *New Holland Cassowary, Dromaius Novæ Hollandiæ* of authors, *D. ater* of Vieillot, and *Dromiceius Australis* of Swainson, *Parembang* of the natives, has become quite familiar to us from the frequency of its exhibition in menageries, and its breeding so readily in a state of domestication. The following is Mr. Bennett's description of this species:—'In size and bulk the *Emeu* is exceeded by the African Ostrich alone. It is stated by travellers to attain a height of more than seven feet, and its average measurement in captivity may be estimated at between five and six. In form it closely resembles the ostrich, but is lower on the legs, shorter in the neck, and of a more thickset and clumsy make. At a distance its feathers have more of the appearance of hair than of plumage, their barbs being all loose and separate. As in the other ostriches, they take their origin by pairs from the same shaft.* Their general colour is a dull brown, mottled with dirty grey, the latter prevailing more particularly on the under surface of the bird. On the head and neck they become gradually shorter, assume still more completely the appearance of hairs, and are so thinly scattered over the forepart of the throat and around the ears, that the skin, which is of a purplish hue, is distinctly visible.' This appearance is most remarkable in the older birds, in which these parts are left nearly bare. The wings are so extremely small as to be quite invisible when applied to the surface of the body. They are clothed with feathers exactly similar to those of the back, which, it should be observed, divide as it were from a middle line, and fall gracefully over on either side. The colour of the bill and legs is of a dusky black; and that of the iris dull brown. There appears to be but little difference in colour between the two sexes; but the young, on first quitting the shell, have a much more elegant livery. A brood of these has lately (1831) been hatched at the Society's garden, in which the ground colour is greyish-white, marked with two longitudinal broad black stripes along the back, and two similar ones on either side, each subdivided by a narrow middle line of white. These stripes are continued along the neck without subdivision, and are broken on the head into irregular spots. Two other broken stripes pass down the fore part of the neck and breast, and terminate in a broad band passing on either side across the thighs. As in the fully-grown bird, the bill and legs are of a dusky hue.'

Food, Habits, &c.—The food of the Emeu consists of vegetables and seeds, but chiefly of fruits, roots, and herbage. In a state of nature it is very fleet and affords excellent sport in coursing with dogs, which are however rather shy of their game, in consequence of the powerful kick that the bird can inflict, so powerful that the settlers say it can break the bone of a man's leg by striking out with its feet. Well-trained dogs therefore, to avoid this infliction, run up a-breast and make a sudden spring at the neck of the bird. Though the Emeu has bred so frequently in captivity, the mode of making the nest in the wild state does not appear to be well known, though it is generally supposed to be a mere hollow excavated in the earth. The dark green eggs are six or seven in number. The birds appear to be tolerably constant in pairing, and the male bird sits and hatches the young, whilst the female watches and guards the nest. The Emeu can produce a hollow drumming sort of note, well known to those who have attended to its manners in captivity. These birds will, like the *Rhea*, take water. Captain Sturt, when descending the Murrumbidgee, in Australia, saw two of them in the act of swimming. They appear to be gregarious, and not very shy in some localities, for Major Mitchell in his excursion towards Port Phillip found them very numerous on the open downs, and their curiosity brought them to stare at the horses of the party, apparently unconscious of the presence of the riders. In one flock he counted thirty-nine, and they came so near that the gallant traveller, having no rifle with him, was tempted to discharge a pistol at them, but without effect.

Geographical Distribution.—Widely diffused over the southern part of New Holland and the neighbouring islands; but gradually disappearing before the encroachment of civilized man. They have also been observed on the west coast (Swan River). Captain Flinders found them in abundance at Port Phillip and King George's Sound, and D'Entrecasteaux at the latter place. Flinders and Péron saw them in numbers at Kangaroo Island.

Utility to Man.—The flesh of the Emeu, particularly the hind quarters, is generally described to be good and sweet eating.

But one species of *Dromaius* has hitherto been recorded: but the indefatigable zoologist Mr. Gould has arrived at the safe conclusion that a second species has existed, if it does not still exist, though he has his fears that it may be extirpated. Two specimens at least, he kindly informs us, exist in the museums; one at the *Jardin des Plantes*, and the other in the Linnean collection. Mr. Gould, to whom we may look for a speedy publication of the characters of this new and most interesting addition to the *Struthionidæ*, has in his MS. designated this smaller species as *Dromaius parvulus*, and has placed that name on the bird in the Paris Museum. By his liberality we are permitted to lay this valuable information before our zoological readers. Mr. Gould believes that portion of Australia called New South Wales to be the habitat of *D. parvulus*.

The *Dromiceius Novæ Zealandiæ* of M. Lesson is no other than the highly curious bird which we must next describe, and which he himself on the next page gives to his readers under its proper name of

APTERYX. (Shaw.)

'If,' writes Professor Owen, 'The *Apteryx* of New Zealand were to become extinct, and all that remained of it, after the lapse of one or two centuries, for the scrutiny of the naturalist, were a foot in one museum and a head in another, with a few conflicting figures of its external form—one representing it in the attitude of a terrestrial bird: another, like that in Dr. Shaw's 'Miscellany,' portraying it erect like a Penguin—the real nature and affinities of this most remarkable species would be involved in as much obscurity, and would doubtless become the subject of as many conflicting opinions among the ornithologists of that period, as are those of the Dodo at the present day.'

In 1812 Captain Barclay, of the ship Providence, brought a specimen from New Zealand, and presented it to Dr. Shaw, who figured it as above noticed. When Dr. Shaw died, this specimen came into the possession of the present Earl of Derby, the president of the Zoological Society of London, then Lord Stanley, and then distinguished, as he is now, for the value and beauty of his collection both of living animals and preserved birds, and his munificent patronage of zoology. M. Temminck placed it with the Dodo among the *Inertes*, but still hardly anything was generally known of the bird till Mr. Yarrell, in 1833, described and figured the Earl of Derby's original specimen, collecting in his paper, in the first volume of the 'Transactions of the Zoological Society, all that had been previously made known on the subject. M. Lesson, in the *Zoologie* of the *Voyage*

* N.B. This is not quite correct. In the African Ostrich the feathers have no accessory plume, neither have those of the Apteryx. A tuft of down represents the accessory plume in the Rhea. In the Emeu this plume equals the original feather, so that the quill supports two shafts. In the Cassowary, besides the double feather, there is also a second accessory plume, so that the quill supports three distinct shafts and vanes. (Owen.)

de la Coquille (1829) had noticed the existence of 'a bird without wings,' fragments of which were brought by the natives, which appeared to him to be those of the Emeu, and he says that M. Kendal had confirmed this idea by affirming the existence of Cassowaries analogous to those of Australia in the woods of New Zealand. He adds that the natives call the bird *Kivikivi*, and hunt it with dogs, and that he doubts not that the bird is the *Apteryx Australis* of Shaw.

In the 'Voyage de l'Astrolabe,' M. d'Urville states that it was in the Bay of Tolaga, or Houa-houa, on the east coast of the most northern of the two islands of New Zealand, that he obtained the first positive intelligence as to the nature of the *Keivi*, as he writes it, from observing a mat or dress (natte) adorned with the feathers of the bird, which is one of the first objects of luxury to the natives. According to them, he adds, the *Keivi* is a bird of the size of a small turkey, but, like the ostrich and cassowary, deprived of the faculty of flight, common in the neighbourhood of Mont Ikou-Rangui, and is hunted at night with torches and dogs. M. d'Urville concludes by remarking that it is probable that these birds belong to a genus closely approximating to the cassowaries, and that he believes that it has already received the name of *Apteryx* from some authors; and he mentions a second time the dresses of the chiefs on solemn occasions as being ornamented with the feathers, and refers to the following note in Cruise's *Journal of a Residence in New Zealand* (1822):—'The Emu is found in New Zealand, though we were never fortunate enough to meet with one. The natives go out after dusk with lights, which attract their attention, and they kill them with dogs. Their feathers are black, smaller and more delicate than those of the Emu of New Holland; and a mat ornamented with them is the most costly dress that a chief can wear.'

MM. Quoy and Gaimard, in the *Zoologie* of the same voyage, allude to the bird, which they found it impossible to obtain, but brought back the mantle of a chief covered with its plumes.

Bill of Apteryx. (Owen.)

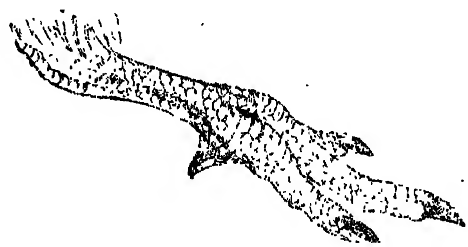
Mr. Gould, who has given beautiful and accurate figures of the bird in his grand work *The Birds of Australia*, states that since Mr Yarrell wrote, he had become acquainted with five additional specimens, and had obtained further information respecting the history of the species. Two of these, from which his figures are taken, were presented to the Zoological Society by the New Zealand Company; and that Society possesses a third but imperfect specimen, presented by Alexander MacLeay, Esq., of Sydney. Two others have been recently added to the collection of the Earl of Derby, one of which his lordship liberally presented to Mr. Gould.

Description.—Face and throat greenish brown; all the remainder of the plumage consisting of long lanceolate hair-like feathers of a chestnut-brown, margined on each side with blackish brown; on the lower part of the breast and belly the feathers are lighter than those of the upper surface, and become of a grey tint; bill yellowish horn-colour, its base beset with numerous long hairs; feet yellowish brown. (Gould.)

This is the *Apteryx Australis* of Shaw; *Apteryx* of Temminck; *Apterous Penguin* of Latham; and *Kivi-Kivi* or *Kiwi-Kiwi* of the aborigines of New Zealand.

The length from the point of the bill to the end of the tailless body is about thirty-two inches; but the bill is much longer in some individuals than in others, and it is not satisfactorily made out whether this difference of length is to be attributed to difference of age or sex; but it has been supposed that the female has the longest bill.

The toes are four in number; the three anterior ones are unconnected. The hind toe is placed on the inner flattened surface of the tarsus; is directed backwards, and almost perpendicularly downwards, it measures only 1¼ inch, and of this the claw or spur measures ¾ of an inch. In the size and position of this toe the *Apteryx* corresponds with the *Dodo*.



Foot of Apteryx.

Food, Habits, &c.—Worms, insects, especially the larvæ of *Lepidoptera*, and probably snails, appear to be the food of this species. Mr. Gould states that the favourite localities of the bird are those covered with extensive and dense beds of fern, among which it conceals itself, and when hard pressed by dogs, the usual mode of chasing it, it takes refuge in crevices of the rocks, hollow trees, and in the deep holes which it excavates in the ground in the form of a chamber. In these latter situations, Mr Gould tells us, it is said to construct its nest of dried fern and grasses, and there deposits its eggs, the number and colour of which have not been clearly ascertained.

Apteryx Australis. (Gould.)

Mr. Short, in a letter to Mr. Yarrell, states that when undisturbed, the head is carried far back in the shoulders, with the bill pointing to the ground; but when pursued, it runs with great swiftness, carrying the head elevated like the ostrich. Its habits are said to be almost exclusively

nocturnal, and the natives usually hunt it by torchlight, seeking for it with the utmost avidity, the skins being so highly prized for the dresses of the chiefs, and indeed the natives can be rarely induced to part with them. The feathers are also used for artificial flies in angling, after the European manner. When attacked, it vigorously defends itself, striking rapidly and dangerously with its powerful feet and sharp spur, with which it is also said to beat the ground, in order to disturb the worms, on which it feeds, seizing them with its bill the instant they make their appearance.

Geographical Distribution.—The *Apteryx* is said to inhabit all the islands of New Zealand, particularly the southern end of the middle island. (*Birds of Australia.*)

FOSSIL STRUTHIONIDÆ.

In November, 1839, Professor Owen exhibited, at a meeting of the Zoological Society of London, the fragment of the shaft of a femur, six inches in length, and five inches and a half in its smallest circumference, with both extremities broken off. This bone of an unknown struthious bird of large size, presumed to be extinct, was put into the Professor's hands for examination, by Mr. Rule, with the statement that it was found in New Zealand, where the natives have a tradition that it belonged to a bird of the Eagle kind, which has become extinct, and to which they give the name 'Movie.' Similar bones, it is said, are found buried in the banks of the rivers.

After a minute description of the bone, Professor Owen proceeds thus:—'There is no bone of similar size which presents a cancellous structure so closely resembling that of the present bone, as does the femur of the ostrich; but this structure is interrupted in the ostrich at the middle of the shaft, where the parietes of the medullary, or rather air-cavity, are smooth and unbroken. From this difference, I conclude the Struthious bird indicated by the present fragment to have been a heavier and more sluggish species than the ostrich: its femur, and probably its whole leg, was shorter and thicker. It is only in the ostrich's femur that I have observed superficial reticulate impressions similar to those in the fragment in question. The Ostrich's femur is subcompressed, while the present is cylindrical, approaching in this respect nearer to the femur of the Emeu: but its diameter is one-third greater than that of the largest Emeu's femur with which I have compared it. The bones of the extremities of the great *Testudo Elephantopus* are solid throughout. Those of the crocodile have no cancellous structure like the present bone. The cancellous structure of the mammiferous long bones is of a much finer and more fibrous character than in the fossil. Although I speak of the bone under this term, it must be observed that it does not present the characters of a true fossil; it is by no means mineralized: it has probably been on or in the ground for some time, but still retains most of its animal matter. It weighs seven ounces twelve drachms avoirdupois.

'The discovery of a relic of a large struthious bird in New Zealand is one of peculiar interest on account of the remarkable character of the existing Fauna of that island, which still includes one of the most extraordinary and anomalous genera of the struthious order; and because of the close analogy which the event indicated by the present relic offers to the extinction of the Dodo of the island of the Mauritius. So far as judgment can be formed of a single fragment, it seems probable that the extinct bird of New Zealand, if it prove to be extinct, presented proportions more nearly resembling those of the *Dodo* than of any of the existing *Struthionidæ*. Any opinion however as to its specific form can only be conjectural; the femur of the Stilt-bird (*Himantopus*) would never have revealed the anomalous development of the other bones of the leg; but so far as my skill in interpreting an osseous fragment may be credited, I am willing to risk the reputation for it on the statement that there has existed, if there does not now exist, in New Zealand, a struthious bird nearly if not quite equal in size to the ostrich.' (*Zool. Proc.*, 1839.)

The account of the bones found buried in the Isle of France and the island of Rodriguez will be found in the article DODO, vol. ix., p. 52.

And here we close an abridged account of perhaps the most interesting family in the whole class of birds, hoping however that no material omission will be found, whilst, through the kindness of friends, we have been enabled to present our readers with some information not previously published. When we look at the bisulcous ostrich, with its large ventricle between the crop and the stomach, and its vast receptacle where the urine accumulates, as in a bladder, we may well excuse the antients for their doubts as to the place of the animal. 'The name of Camel-Bird, by which it was known not only to the Greeks and Romans, but also to the nations of the East; the broad assertion of Aristotle that the ostrich was partly bird and partly quadruped; and that of Pliny, that it might almost be said to belong to the class of beasts, are,' as Mr. Bennett well says, 'but so many proofs of the popular recognition of a well authenticated zoological truth.' In the *Cassowary*, the *Emeus*, and the *Apteryx*, the covering of the body becomes something between feathers and hair: in the *Cassowary* and *Emeu* the wing is dwindling rapidly; and in *Apteryx* this great characteristic of the birds is reduced to a mere rudiment; while in all, the lower extremities, with which they kick like quadrupeds, are most highly developed.

STRUTT, JOSEPH, an artist and antiquary of considerable merit, was born at Springfield, in Essex, Oct. 27, 1749. His father was the owner of a mill at Springfield. At the age of fourteen the son was apprenticed to the unfortunate William Wynne Ryland, the engraver, and afterwards became a student of the Royal Academy, where he tried his talent at painting in oil. In 1771 he became a student in the reading-room of the British Museum, the manuscript stores of which gave a new bias to his pursuits, and where he conceived, and obtained the chief embellishments for, most of the literary labours which he afterwards executed.

In 1773 he published his first work, 'The Regal and Ecclesiastical Antiquities of England, containing the representations of the English monarchs from Edward the Confessor to Henry VIII.,' a thin volume in quarto; a new edition of which he published, with a Supplement, in 1793.

In 1774 he published the first volume 4to. of what he called '*Horda-Angel-Cynnan*, or a complete View of the Manners, Customs, Arms, Habits, &c. of the Inhabitants of England, from the arrival of the Saxons; the second volume of which appeared in 1775, and the third in 1776.

In 1777 and 1778 he published his 'Chronicle of England,' in 2 vols. 4to. He had intended to bring this work down to his own time in six volumes, but not meeting with the encouragement he looked for, he stopped at the Norman Conquest.

His next work was 'A Biographical Dictionary, containing an Account of all the Engravers from the earliest period to the present time, illustrated by engravings,' 2 vols. 4to., London, 1785 and 1786; a work very creditable to his judgment and industry.

In 1790 an asthmatic complaint rendered a country residence necessary, when he retired to Bacon's farm in Hertfordshire, where he employed a part of his time in engraving a series of plates in illustration of 'Pilgrim's Progress.' Here he remained for four or five years.

In 1795 he returned to London, and began collecting materials for his 'Complete View of the Dress and Habits of the People of England from the establishment of the Saxons in Britain,' the first volume of which he published in 1796, and the second in 1799.

In 1801 he published the last work he lived to complete, on 'The Sports and Pastimes of the People of England,' 4to.: reprinted in 1810, 4to., and again in 8vo. edited by William Hone, in 1830.

He died, in narrow circumstances, in Charles Street, Hatton Garden, October 16th, 1802. He left some manuscripts in the possession of his son, from which 'Queen Hoo Hall,' a romance, and 'Antient Times,' a drama, in 4 vols. 12mo.; and 'The Test of Guilt, or Traits of Antient Superstition, a dramatic tale, with the Bumpkin's Disaster, &c.' 4to., have been since published.

Nichols, in his 'Literary Anecdotes,' whose account we have principally followed, enumerates (vol. v., p. 685, 686) a considerable number of single plates which Mr. Strutt engraved and published, as well as a few paintings in oil and drawings.

STRUVE, GEORG ADAM, was born at Magdeburg, on the 26th of September, 1619. His father, the proprietor of Wandesleben, was judge in the supreme court of the duchy of Magdeburg. The family of Struve came originally from Brunswick, in which the grandfather of the subject of this sketch possessed an equestrian fief. Some of the ancestors of the mother of G. A. Struve had occupied high judicial offices, and others had pursued, with success, the career of University honours.

Struve's father was too much occupied by his judicial

duties to superintend the minute details of his son's education; but his mother laboured anxiously to instil devotional feelings into his infant mind. He received instruction in the first elements of Latin, and other branches of knowledge, at the lyceum of Magdeburg, until he attained his eleventh year. In 1630 he was sent to the gymnasium of Schleusingen, where he remained till 1636. His principal tutor was Reyher, a man of great reputation as a teacher, who, besides grounding him thoroughly in Greek and Latin, imparted to him some notions in philosophy and belles-lettres.

His family had suffered much during these six years from the destruction of Magdeburg by Tilly's army, and the devastation of the district in which their property lay. They led an unsettled life for several years, sometimes in one town, sometimes in another, till the storm of war having drifted into other provinces, they ventured again to take up their abode at Magdeburg. Not long after their return, Georg Adam arrived at the house of his parents a few days sooner than he was expected. Six years had so completely changed his appearance, that he was received as a stranger both by his parents and sisters, who did not recognise him until he declared himself.

In June, 1636, Struve entered the University of Jena. The taste which he had acquired for literature and science, under his schoolmaster, prompted him, although the law was his professional study, to devote a good deal of time to the philosophical classes. He attended the lectures of Philip Herst upon ethics; of Daniel Stahl upon logic and metaphysics, of Johann Zeisold upon physics, of Johann Michael Dehlerr upon oratory and history. These were branches of knowledge which the jurists of his day were only in a few rare instances beginning to cultivate, but he found, in after-life, advantage from this preliminary intellectual discipline. Even at this early age, if we may credit the narrative of his son, he had become aware of the important lights which a study of history was calculated to throw upon the doctrines of law, and the advantage a lawyer might derive from cultivating a logical precision in the statement of his arguments and an elegant diction. So strong was his sense of the latter requisite, that, in addition to the public lectures on rhetoric, he attended private classes for practical exercise in oratory. Seeing also how much depended in law upon precision of language, he extended his inquiries into the field of philology.

All these pursuits however were carried on in subordination to his legal studies. He attended the lectures of Peter Dieterich, Erasmus Ungebauer, and Ortholph Fomman. The last-mentioned was a relation of Struve's mother, and the young man had been confided to his superintendence, a trust which he conscientiously discharged by a watchful direction of his private studies. Struve had no relish for the wild merriment which then, even more than in modern times, was characteristic of the German student. He seems to have been of a quiet and even timid disposition, for a fright that he got from some soldiers, when a marauding party plundered Jena, soon after his arrival at the University, impaired his health sensibly for several years. His irreproachable conduct prepossessed the professors in his favour; and the distinguished appearance he made in a disputation which he maintained, in the philosophical faculty, on his thesis 'De Victoria et Clade,' in 1638, raised great expectations of his future eminence. He quitted Jena on the 11th of September, 1639, and his public certificate from the heads of the University was more than usually flattering.

He remained upwards of a year in his father's house for the purpose of re-establishing his health, which had not yet recovered from the effects of the shock above alluded to. In the year 1641 he entered himself at the University of Helmstädt, where he remained till April, 1645. Hermann Conring was then in the vigour of life: Struve attended during the summer of 1641 his lectures on the history of antient Germany, to which the 'Germania' of Tacitus served as a text-book. In the winter of the same year he heard Rudolph Diephold's lectures upon 'genealogia historica,' as a supplement or continuation of Conring's; whose lectures upon politics he attended at the same time. In 1642 he was a member of a class to which Conring expounded the 'Politics' of Aristotle. Heinrich Hahne, at that time the most esteemed civilian in Germany, had ceased to lecture, but Struve was fortunate enough to be selected as his amanuensis on some occasions, and heard the 'Pandects' explained by his colleague Wesenbeck. His relation with Conrad Horn was more intimate, for his father had placed him under the immediate control of that professor, who exercised him, along with his other pupils, unremittingly in private disputations. In January, 1642, Struve maintained a public disputation in the juridical faculty, on a thesis 'De Damnis, illis præcipue quæ ex dolo, culpâ, aut casu proveniunt, harumque correctionibus et præstationibus.' And in July, 1643, he maintained one in the philosophical faculty, on a thesis 'De Ducibus et Comitibus Imperii Germanici.' In February, 1645, he again supported a juridical thesis 'De Vindicta Privata;' and having been admitted to the preliminary examinations, received his licence as candidate for the degree of Doctor of Laws.

Two months thereafter, before he had completed his 26th year, he was appointed by Augustus, duke and archbishop of Magdeburg, assessor to the magistrates of Halle, an office which he retained not quite a year and a half. In the month of February, 1646, he received as a matter of course the title of Doctor; and in the December following he was called to fill the chair of law in the university of Jena, left vacant by the death of Fibigius. He was admitted an assessor to the magistracy in January, 1647; and in June, 1648, an assessor to the high court of the circle of Saxony. He continued in the discharge of his judicial and academical duties till 1667. His opinions were in great request both in controversies relating to public and those relating to private rights. The town of Brunswick, being at that time involved in a dispute regarding its privileges with the duke, requested Struve to undertake the management of their legal business; and he, having obtained the consent of the patrons of the university, was appointed, on the 26th of March, 1661, counsel in ordinary to the good town of Brunswick for three years, with an annual salary of 300 dollars, becoming bound to advise its magistrates in writing whenever called upon, and, if necessary, to visit the town four times in the year. The duke and town having settled their dispute by a compromise, this connection was dissolved in December, 1663. At first Struve lectured upon the 'Institutes,' a duty devolving upon the youngest professor. As his seniors died off, he was called in succession to lecture upon the 'Pandects,' the 'Code,' and ultimately upon feudal law. Entertaining from his own experience a high opinion of the benefit to be derived from disputations, he encouraged his pupils to engage in them frequently among themselves under his guidance; and in course of time the idea suggested itself to him of making the young men maintain in succession disputations on all the leading doctrines of the branch of law he might be lecturing upon at the time. From a series of theses impugned and defended in this manner arose his 'Syntagma Juris Feudalis,' first published in 1653, and his 'Syntagma Juris Civilis,' first published in 1658.

He received unexpectedly, in the year 1667, the appointment of privy counsellor to the dukes of Weimar, and transferred himself with his family to the seat of government in the month of December. His discharge of the duties of this office gave so much satisfaction, that when the line of Saxe-Altenburg became extinct in 1672, and doubts were entertained whether the line of Gotha or Weimar had the nearest claim to the succession, he was selected as the ablest person to advocate the cause of his masters. In the conduct of this delicate business he had the merit or good fortune to give entire satisfaction, both to the party for whose interests he acted, and that to which he was opposed. When the territories of the house of Weimar were divided between the brothers, he remained in the service of the duke of Weimar. Notwithstanding the load of public business which devolved upon him during this period of his life, he contrived to find some time for the literature of his profession. He published in 1669 answers to objections which had been urged against some of the doctrines maintained in his 'Syntagma Juris Civilis,' a work which had however been completed before he left Jena. He compiled his remarks on the 'Immo' of Gothofredus, which his son Burkhard Gotthelf published at Frankfort after his death. In 1668 he published 'Jus Sacrum Justinianeum.'

The Ordinarius of the Judicial College of Jena died in 1674; and notwithstanding the active competition of the most distinguished German jurists for so honourable and lucrative an employment, Struve was selected by the patrons of the university as the best qualified for the office, along with which the professorship of canon law was then uni-

formly held. On the 28th of July, he made with his family a sort of triumphal entry into Jena; for the citizens and the members of the university met him in procession at some distance from the town. The important offices to which he had been appointed he continued to fill till his death, although the active discharge of their duties was interrupted for a time by the affairs of the regency of Jena.

On the death of Duke Bernard, to whose share the duchy of Jena had fallen at the partition of the Weimar territories, his son Johann Wilhelm, a minor, succeeded. His uncle Johann Ernest of Weimar was guardian, but it was deemed expedient that a permanent council of regency should sit at Jena. Struve was appointed president of this body about the end of August, 1680. In virtue of this appointment, the whole burden and responsibility of the general executive government of the territory, the discharge of the consistorial business, and the management of the finances, fell upon his shoulders. He was obliged to relinquish to another the discharge of his professorial duties, reserving however his appellate jurisdiction as ordinarius. So many cares naturally distracted his attention from his own private concerns, which were considerably dilapidated in consequence of his elevation. His pre-eminent position too exposed him to much malevolence; but he laboured indefatigably, and gave satisfaction both to the duke of Weimar, and to the duke of Eisenach, who at his death succeeded him in the regency. The young duke of Jena died towards the close of 1690, not long after a partition was agreed to by the lines of Weimar and Eisenach, and the council of regency being dissolved in consequence, Struve was restored to his academical functions.

His life at Jena, both before and after this interruption, though a busy was a uniform one. As privy counsellor he attended every consultation to which he was summoned by the dukes his masters. As Ordinarius he presided both in the ordinary and appellate tribunals of Jena. He prepared opinions in reply to the cases addressed by numerous applicants either to the Judicial College of Jena or to himself individually. In addition to these occupations, he faithfully expounded to his pupils the doctrines of the canonical law as then received in the courts of the Protestant states of Germany. After the dissolution of the regency, he did not again enter the academical chair, but continued nevertheless, with unabated diligence, to urge on the literary undertakings to which his professional duties had prompted him, and which, even whilst acting as vice-regent, he had not neglected. He prepared a new edition, with notes explanatory of the points in which the Lutheran deviated from the Roman Catholic system of canon law, of Valerius Andrea's treatise on that branch of jurisprudence, which he used as a text-book; but it was not published till 1680, when other cares prevented him from continuing his lectures. The chief ambition of his later life was to bring the canonical law of Protestant Germany into a better and more systematic form. With that view he projected various works; but on account of their extent, and the interruptions he experienced, only fragments of them were completed. A projected 'Jurisprudentia Canonica,' after the model of his own 'Jurisprudentia Romano-Germanica,' remained a mere project. Of a complete 'Commentary on the Five Books of the Decretals,' only that which relates to the fifth book, 'De Delictis,' was published, at Jena in 1691: it appears that his son Georg Gottlieb acted as editor. It was his intention to treat the doctrine of marriage in a much fuller manner in his annotations on the fourth book: valuable materials were collected for the purpose; and he had resolved making his son Burkhard Gotthelf digest them under his own superintendence and direction, but the young man preferred accepting the invitation of his brother at Darmstadt, as has been noticed in the preceding article. The materials for a projected treatise 'De Causis et Beneficiis Ecclesiasticis' were in like manner left unarranged at his death. The materials and plans of the great structure he contemplated alone survived him. He found time, amid all his labours, to compile a system of the common law of the Empire in the German language, a work which was undertaken at the request of Duke Ernest of Gotha, and published in 1689. It was the first German treatise of the kind, and gave a severe shock to the prejudices of most of his contemporaries. The autumn before his death he undertook to prepare an edition of the 'Criminalia' of Carpzovius for a Leipzig bookseller, but death prevented him.

His son remarks that his energy and love of life seemed materially to abate after the shock he received by the death of the young duke. He continued however without intermission the arduous duties of his office, and was seized in court with the illness which carried him off in less than twenty-four hours. It was a maxim which he was fond of repeating, that 'the Ordinarius of Jena ought to die standing.'

Georg Adam Struve was twice married. His first wife was the daughter of Christopher Philip Richter, whom he succeeded as Ordinarius. They were married on the 6th of November, 1648, and lived together fourteen years, during which time she brought him eight children, all of whom died before him except two, Friedrich August, who inherited the property of his maternal grandfather, and died two years after his father, and Johann Wilhelm, a practising lawyer of considerable eminence, long resident in Darmstadt, of whom mention has been made in the preceding article. Conscious that his professional duties incapacitated him from paying the necessary attention to the education of his children, Struve, soon after the death of his first wife, began to look about for a second. His choice fell upon Susanna Berlich, daughter of a distinguished lawyer resident in Dresden. They were married on the last day of October, 1663; and she survived him six years. She brought him seventeen children, of whom four sons and one daughter survived him. Three of the sons, Georg Gottlieb, Burkhard Gotthelf, and Friedrich Gottlieb, embraced the legal profession, but only the second attained to any eminence. Ernst Gotthold was a practising physician in Brunswick. Two of Struve's daughters married lawyers: so that he descended from one line of jurists, and was the progenitor of another.

His published works are—'Syntagma Juris Feudalis,' Jenæ, 1653; ibid., 1659; Frankfort, 1703-4. To the later editions are appended 'Observationes feudales juxta syntagmatis juris feudalis ordinem digestæ;' 'Decas Consiliorum et Responsorum Feudalium.' and 'Centuria Decisionum, quænam res feudales, quænam allodialis.' 'Syntagmata Jurisprudentiæ Civilis,' Jenæ, 1665 (frequently reprinted); 'Jurisprudentia Romano-Germanica Forensis,' Jenæ, 1670; 'Jus Sacrum Justinianeum, sive Progymnasmata ad Titulos priores Libri i. Codicis,' Jenæ, 1668, 4to.; 'Evolutiones Controversiarum in Syntagmata Juris Civilis comprehensarum,' Jenæ, 1669; 'Triga Dissertationum: de Vindicta privata et retorsione juris iniqui; de aedificiis privatis; et de annona,' Jenæ, 1670; 'Dissertationes Criminales XVI. in academia Salana publicæ disquisitioni præpositæ,' Jenæ, 1671; 'Decisiones Sabbathinæ, Canonicæ et Practicæ; Selectiones de Conventionibus et Contractis,' Jenæ, 1677, 4to.; 'Notæ et Observationes Theoreticæ, Canonicæ et Practicæ, ad Antonii Matthaei Tractatum de Successionibus,' Jenæ, 1678, 4to: 'Valerii Andreæ Desselii Erotemata Juris Canonici, cum animadversionibus,' Jenæ, 1680 and 1691, 8vo.; 'Dissertatio Juridica de Invocatione Nominis Divini,' Jenæ, 1682, 4to.; 'Jurisprudentz, oder Verfassung der Landüblichen Rechte,' Mersburg, 1689, 8vo.; 'Commentarius ad Librum V. Decretalium de Delictis, Cura Georgii Gottlebii Struvii,' Jenæ, 1691, 4to.

The writings of Georg Adam Struve indicate a mind which, as far as it could see, saw distinctly and correctly. He belonged, notwithstanding his studies in philosophy and history, rather to the race of jurists which preceded him, than to the more accomplished race which succeeded him. His historical erudition is very deficient in critical discrimination; and he labours painfully to torture the doctrines of law into the formulæ of scholastic logic. It was as a practical lawyer that he distinguished himself; a character for which perhaps even the limited range of his mental vision peculiarly qualified him; but towards the formation of which his robust yet tranquil constitution both of mind and body, his clearness of apprehension, self-possession, and moral courage, but above all his high and pure sense of moral rectitude, were invaluable ingredients. His influence in the development of German jurisprudence was exercised as presiding judge in an important appellate tribunal; as a consulting lawyer whose opinions were highly valued throughout all Germany; and as a judicious former of the minds of youth. He worked more through the jurists he trained, than by his own works. Georg Adam Struve was one of those robust, quiet, powerful natures which are of more importance in society than nine-tenths of the more glaring personages who engross the admiration of the multitude.

(*Pii Manes Struviani, sive de Vita et Scriptis Georgii Adami Struvii, Illustris quondam Jurisconsulti quibus*

justa persolvit mœstissimus filius Burcard Gotthelf Struve, Jenæ, apud Johannem Bielkium, 1705.)

STRUVE, BURKHARD GOTTHELF, third son by the second marriage of Georg Adam Struve, was born at Weimar on the 26th of May, in the year 1671, and was carried to Jena when his father transferred his residence to that University, on receiving the appointment of Ordinarius of the Judicial College there, in 1674. Great pains were taken with his education by his parents: and in after-life Struve often acknowledged his obligations to Johann Friedrich Durre, who had the charge of his elementary education. An incident mentioned in the Memoir of his father, which he published in 1705, almost leaves the impression that the old gentleman treated him in boyhood like a favourite plaything. The last time Georg Adam Struve presided at the creation of a number of doctors of law, in the year 1680, he commanded Burkhard, then a boy of nine years only, to make his remarks, and put questions with the rest of the assembly.

Not long after this event the boy was sent to the gymnasium at Zeitz, and confided to the care of Christopher Cellarius, rector of the institution. Young Burkhard made himself so useful to his preceptor, both in his private study and in the public library, that he gained his confidence sufficiently to be employed as an assistant upon the corrected and enlarged edition of Faber's 'Lexicon,' which he had undertaken to publish.

Burkhard Gotthelf Struve, having attained his seventeenth year, returned to Jena for the purpose of commencing his university studies, in 1788. His father, who was then engrossed with the labours which fell to his share as president of the regency of the duchy of Jena, had relinquished for a time the active discharge of the professorial office At the urgent request of his son however he consented to give private instruction, on Wednesdays and Saturdays, to him and eleven of his young associates, in the system of Romano-Germanic law recognised by the tribunals of Germany, and the plan of tuition pursued was to examine the pupils upon the elementary treatise on this branch of law compiled by their instructor, and to exercise them in arguing upon controverted doctrines. Burkhard attended at the same time the prelections of Johann Hartung and Peter Müller in Roman law. He seems however to have been a more assiduous frequenter of the literary classes of Jacob Müller, Andreas Schmidt, and especially of Georg Schubart, then rector of the University, under whose presidency he held, in 1689, a public disputation upon some theses appended to his dissertation 'De Ludis Equestribus.' Not long after he disputed in the juridical faculty on the legal doctrines 'De Auro Fluviatili;' and on both occasions he is said to have impressed his auditory with admiration of his precocious talents. While thus engaged, he did not neglect pursuits more consonant to the tastes of his age, country, and academical associates. He learned dancing, and was for a time a frequent attendant in the fencing-school. Tiring however of these pursuits, he devoted himself with ardour, in his leisure hours, to the study of the French language. In the Memoir of his father, already alluded to, he mentions that about this time he was employed by his father in a collation of his Latin treatise 'Jurisprudentia Romano-Germanica Forensis,' with his work on the same subject in German, to show that the one was not a mere translation of the other, but a different work. The statement which Burkhard drew up on this occasion was meant to be inserted in the pleadings of the publisher of the German work, against whom the publisher of the other had brought an action; but it was published, at a later period, by the bookseller, as a preface to a new edition, without the compiler's knowledge or consent. An exercise of this kind, and the repetitions under his father, were well calculated to impress the leading doctrines of the law upon his memory.

Towards the close of the same year in which he maintained his first public disputations, Burkhard Gotthelf Struve repaired to the university of Helmstädt, for the purpose of studying history under Heinrich Meibom, and civil law under Georg Engelbrecht. After a year's residence at Helmstädt he went to Frankfort on the Oder, in order to profit by the instructions of Samuel Stryk and Peter Schulz. During his abode at Frankfort he engaged in a controversy which led him to appear for the first time in print. An obscure jurist of the name of Schnegas had published, in 1689, a treatise 'De Concursu Creditorum,' in which he attacked some doctrines laid down by the elder Struve, in his 'Institutes of Forensic Law,' regarding the classification of creditors and the right of property in dowry. Burkhard asserted the correctness of his father's views in a pamphlet, which he called 'Struvius non Errans,' and which, to judge by the warmth with which he speaks of the controversy at a much riper age, must have been rather bitter. Schnegas replied in the same strain, but his young antagonist was induced by the advice of older and cooler friends to allow the matter to rest.

In 1691 Stryk having accepted of a chair in the university of Wittenberg, Struve returned to Jena, and was soon after sent to Halle by his father, with a view to his attending the sittings of the supreme court there, in order that he might make himself master of the forms of process. The dry details of legal practice were repulsive to a mind early accustomed to the self-indulgent habits of the abstract student, and to the applause attendant upon skill in mere literary controversy. Instead of frequenting the court, he directed himself almost exclusively to the theory and antiquities of public and feudal law. In such a frame of mind he lent a willing ear to the inducements held out by an elder brother to make a tour to Belgium, and afterwards join him at Darmstadt, where he was established as a practising lawyer. He in consequence visited in succession Gotha, the Hague, Amsterdam, Rotterdam, and Leyden, and was everywhere, on account of his father's reputation, kindly received. He afterwards confessed that his thoughts during this journey were rather distracted by the gaiety and splendour of the towns he visited, than earnestly bent upon extending his knowledge; nor was this very unpardonable in one who had only completed his twentieth year. He did however derive some benefit from the conversation of distinguished scholars in Utrecht and Leyden.

At the request of his brother he repaired to Frankfort to take charge of some business for the transaction of which he required a confidential agent in that town. It was the time of the fair, and the novelty and bustle of the scene left a lasting impression upon Struve's mind. The affairs which required his presence there being arranged, he returned to the Hague, and, the first distraction of travelling having worn off, settled to study. The favourite pursuits of the Dutch literati extended his field of inquiry. On the one hand, the Hague being then a centre of an active diplomacy, his investigations regarding public law were enabled to assume a more practical and real character. The literary pursuits too of his new associates had more of the tone of society than those which prevailed in the German universities. On the other hand, the museums of Holland, and especially the collections of coins and other antiquities, attracted him to inquiries for which his investigations into the antiquities of feudal law had in some measure prepared him. During his residence at the Hague he was indefatigable in his visits to all the museums and libraries, and in his study of the periodical literature, which opened in a manner a new world to him. He made for himself a considerable collection of coins and antiquities. While thus engaged, and projecting a tour through Spain and Great Britain, he was seized with a violent illness, which interrupted his pursuits.

On his recovery he rejoined his brother, and was employed by him at various times to conduct actions for him in the courts of Darmstadt, Stuttgard, and Cassel. He was induced about this time by the fair promises of a Livonian nobleman to undertake a journey in his company to Sweden for the purpose of obtaining a more intimate acquaintance with the antiquities of Scandinavia. Struve with this view proceeded to Hamburg, where he was to be joined by his companion. The count not making his appearance however, he returned to his brother, and in the same year (1692) visited Wetzlar, for the purpose of obtaining, by attending the sittings of the imperial court, a more accurate knowledge of the practice of public law. While thus engaged, he was attacked by a more severe illness than the preceding; and some of the symptoms induced a suspicion that it was occasioned by poison. No sooner was he convalescent than he received intelligence of the death of his father, and was obliged to leave Wetzlar in order to look after his share in the inheritance. During the period which elapsed between his quitting the university and his return to Jena, his mind, though stimulated to greater activity and familiarised with objects of greater reality and importance than had previously engaged his attention, had been dissipated and distracted with

their multiplicity. To the end of his life he occasionally expressed regret that he had not, in compliance with the request of his father, remained at Jena, to digest under his direction his collections for a commentary on the law of marriage, an occupation which must have contributed to give him more precision and more command over his thoughts.

On his return to Jena, Struve found one of his brothers eagerly engaged in pursuit of the philosopher's stone. He was of a facile disposition, as is apparent from an anecdote he relates in the Life of his father, of his incurring a rebuke by undertaking to solicit privately for a person whose conduct was under judicial investigation. This easiness of temper at first led him to join in his brother's experiments, but the frenzy seized him in turn, and he was soon as zealous an adept as the other. As might have been anticipated, the search after the secret of making wealth ended in beggaring both. The brother was only saved from a gaol by Struve selling the collection of curiosities he had made in Holland, and even a part of his wardrobe. To the intoxication of his golden dreams succeeded a state of miserable depression which lasted for two years. He secluded himself from society, and absorbed himself in the study of the Scriptures and the theological writings of Tauler and Arndt.

When he recovered his elasticity of mind, he found himself unable to encounter the expense of following out the academical career to which his father had destined him. Some time elapsed before any prospect of employment opened to him. In 1695 he published at Frankfort on the Main some notes on the legal doubts of Gothofredus (known among jurists as the *Immo* of Gothofredus), from a manuscript of his father. In 1696 he published a letter to his old teacher Cellarius, 'De Bibliothecarum harumque Præfectis.' At last, in 1697, he was appointed by the patrons of the university of Jena curator of the library. Upon receiving this appointment, he opened private classes, giving instruction, according as his pupils desired, in physics, the elements of the Greek language, Roman antiquities, or history. The number of young men who attended him excited the envy of the established teachers, and drew down upon him the active enmity of Schubart. It was found necessary to provide himself with a legitimation as teacher; and for this end he, in the year 1702, took the degree of Doctor of Law and Philosophy at Halle, the usual fees being remitted at the solicitation of Stryk and Cellarius.

As soon as he obtained his degree, he took measures for having himself enrolled as Doctor Legens at Jena, and his subsequent career was one of uninterrupted success. On the death of Schubart, he was appointed to the chair of history, and he commenced the discharge of its duties in 1704, by publishing a programma 'De Vitiis Historicorum,' and delivering a public oration 'De Meritis Germanorum in Historiam.' His fame as a public teacher attracted many of the young nobility from all parts of Germany, and among others Prince Ernest Augustus, afterwards duke of Weimar. Having received, in 1712, an invitation to the university of Kiel, he was induced to decline it by the patrons of Jena conferring upon him the office of historiographer to the university, the rank of counsellor, and the appointment of extraordinary professor of law. He was promised the succession to the ordinary professorship of feudal law, which he actually obtained a few years later. In 1717 he was appointed a privy counsellor by the reigning prince of Baireuth; and in 1730 he received the same compliment from the Saxon court. He repeatedly filled the office of Dean in the Philosophical Faculty, and was thrice chosen rector of the university. He died on the 24th of May, 1738, having nearly completed his sixty-seventh year.

Struve was thrice married. He was united to his first wife, Anna Elizabetha Bertram, daughter of an assessor in the court attached to the salt-works of Halle, in 1702, who died in 1706, leaving him two daughters. He married in 1707 his second wife, Rogina Elizabetha Ständler, daughter of the town-clerk of Naumburg on the Sala; the year of her death is uncertain; she left no surviving children. In 1724 he married Sophia Maria, widow of Ernest Friedrich Kittoner, a clergyman in Quedlenburg, who brought him no children.

The published works of Burkhard Gotthelf Struve are very numerous. A complete list of them is given in the 'Acta Eruditorum' of Leipzig, published in 1740. The following are the most important, either on account of their subjects and inherent interest, or of the indications they give of the progress and direction of the author's studies:—'Struvius non Errans,' Franc. ad Viad., 1691, 4to.; 'Bibliotheca Numismatum Antiquorum,' Jenæ, 1693, 12mo.; 'Piа Mœstis Desideria in Obitum Susannæ Berlichiæ, matris piissimæ,' Jenæ, 1699, 8vo.; 'Didaci Saavedræ Abriss eines Christlichen Politischen Prinzen,' Jenæ, 1700, 12mo.; 'Antiquitatum Romanarum Syntagma, sive de Ritibus sacris Systema absolutius, adjecta Bibliotheca, Figuris æneis, et Indicibus necessariis,' Jenæ, 1700; et auctior., 1729, 4to.; 'Acta Literaria ex MStis edita et collecta' (17 fasciculi collated, with the date 1713 on the title-page); 'Bibliotheca Juris Selecta,' Jenæ, 1703 (frequently republished, ultimately with additions by Buder); 'Introductio ad Notitiam Rei Literariæ, et Usum Bibliothecarum,' Jenæ, 1704 (contains the 'Dissertatio de Doctis Impostoribus,' published separately by the author in the preceding year); 'Bibliotheca Philosophica in suas classes distributa,' Jenæ, 1704, 8vo. (frequently republished latterly with additions by Kahl); 'Selecta Bibliotheca Historica,' Jenæ, 1705, 8vo. (republished with additions by Buder); 'Pii Manes Struviani, seu de Vitis et Scriptis Georgii Adami Struvii,' Jenæ, 1705, 8vo.; 'Syntagma Juris Publici Imperii Romano-Germanici,' Jenæ, 1710, 4to. (republished in 1711; and again much enlarged, with the title 'Corpus Juris Publici I. R. G.,' in 1738); 'Syntagma Historiæ Germanicæ, à primâ gentis origine ad annum usque 1716,' Jenæ, 1716, 4to. (subsequently published in an enlarged form, with the title 'Corpus Historiæ Germanicæ, à primâ gentis origine ad annum usque 1730, ex genuinis historiarum documentis, coævorum scriptorum monumentis, diplomatibus, et ex actis publicis, illustratum cum variis observationibus et figuris æneis, adjecto indice locupletissimo, et opusculis ad historiam Germanicam facientibus; præmissa est Chrest. Gottl. Buderi Bibliotheca Scriptorum Rerum Germanicarum, easdem universum illustrantium,' Jenæ, 1730, fol. (a German translation of this work has been published); 'Historia Juris Romano-Justinianei, Græci, Germanici, Canonici, Feudalis, Criminalis, et Publici,' Jenæ, 1718, 4to.; 'Einleitung zur Deutschen Reichs Historie,' Jenæ, 1724, 8vo.; 'Corpus Juris Publici Academicum,' Jenæ, 1726, 8vo (thrice republished); 'Compendium Juris Feudalis,' Jenæ, 1727 and 1737, 8vo.; 'Kurtzer Entwurff zur Einleitung zur Wissenschaft der Staaten von Deutschland,' Jenæ, 1733, 8vo. (the title of this work contains the term 'scientia statistica,' the invention of which has been attributed to Achenwall); 'Corpus Juris Gentium, sive Jurisprudentia Heroica ex Juris Naturæ et Gentium Argumentis petitum, et innumeris exemplis ex actis publicis editis et ineditis, historiarumque monumentis, omnis ævi illustratum' (this work occupied thirty years of its author's life, was left complete, but unpublished, at his death, and appeared at Jena in 1743, edited by J. Aug. Heifeld).

Much of the reputation of Burkhard Gotthelf Struve during his lifetime seems to have proceeded from his personal amiability, and from his usefulness as a general index. His style is heavy, and his thoughts scarcely ever original or striking. His services to the literature of history and jurisprudence are great, but they are mainly the services of an able librarian and index-maker. To him perhaps rather than to Achenwall belongs the merit of having given a more systematic form to the statistical branch of education as taught in the universities of Germany—an important department of information, but too apt to spread out into trivial diffuseness.

(*Nova Acta Eruditorum*, anno 1740 publicata, Lipsiæ, 1740; *Ad Nova Acta Eruditorum quæ Lipsiæ publicantur Supplementa*, Tomus iv., Lipsiæ, 1742; *Pii Manes Struviani, sive de Vita et Scriptis G. A. Struvii*, Jenæ, 1705; *Bibliothèque Germanique*, tomes viii. et xliii., Amsterdam, 1724 and 1738; Martini Lipenii *Bibliotheca Realis Juridica*, Lipsiæ, 1757.)

STRY, THE CIRCLE OF, in the kingdom of Galicia, is bounded on the north and north-east by that of Brzezan; on the south-east by that of Stanislawow; on the west by that of Sambor; and on the south by the kingdom of Hungary. Its area is 2170 square miles, and the population is probably not much under 220,000, of whom 13,000 or 14,000 are Jews. The whole circle is mountainous, and it is only on the north-east and north-west sides that there are some small plains. The valleys between the mountains are however tolerably fruitful. The principal river is the Dniester, which however only flows through the north-east part of the circle; the Stry falls

into the Dniester near Zybaczow. There are numerous small rivers and torrents. Agriculture is not carried on to any great extent; the inhabitants grow however corn, rye, barley, and oats, and a considerable quantity of potatoes and flax. The forests are extensive, and the consumption of wood is very great, partly for the salt-works, and partly for the iron-forges. Hassel observes that the number of cattle of all kinds was small, there being in 1817 only 4146 horses, 29,935 oxen, 35,392 cows, and 29,935 sheep. An official table for 1830 shows a very great increase, except in the number of sheep, viz. 10,544 horses, 47,491 oxen, 44,629 cows, and 21,921 sheep. There are no manufactures.

Stry, the capital of the circle, is situated in a tolerably fertile and well cultivated country, on the left bank of the river of the same name, over which there is a wooden bridge. It is surrounded with walls and ditches, and is one of the best towns in Galicia: about half of the inhabitants are Jews. The population is about 6000. There are one Roman Catholic and one United Greek church, a synagogue, a castle, and several schools.

(Blumenbach, *Gemälde der Oesterreichischen Monarchie:* Anonymous, *Historisch-Statistischer Umriss von der Oesterreichischen Monarchie; Oesterreichische National Encyclopädie.*)

STRYCHNIA, a vegetable alkali obtained from the *Strychnos Nux-vomica*, in which it exists combined with the Igasuric or Strychnic acid. Its properties are, that it is colourless, inodorous, crystalline, unalterable by exposure to the air, and extremely bitter. It requires more than 6660 times its weight of cold water, and 2500 times of boiling water for solution. It is insoluble in absolute alcohol or in æther, but in diluted alcohol it is to a certain extent soluble, and the solution by spontaneous evaporation yields crystals in the form of the octohedron, and of a square prism terminated by four-sided pyramids.

It acts like other alkalis on vegetable colours, and neutralises and forms salts with acids. It is extremely poisonous; one-eighth of a grain is sufficient to kill a dog, and a quarter of a grain produces a decided effect upon a man. As usually obtained, which is by a tedious and complicated process, it is probably mixed with some *brucia*, another extremely powerful vegetable alkali.

It is composed of—

Sixteen equivalents of hydrogen	.	16 or	6·8
Thirty equivalents of carbon	.	180 ..	77·0
Three equivalents of oxygen	.	24 ..	10·2
One equivalent of azote	.	14 ..	6·0
Equivalent	.	234	100·

It is employed in medicine.

STRYCHNIC ACID. This acid, as already noticed, exists in the *Strychnos Nux-vomica* in combination with strychnia. It is soluble both in water and in alcohol, and has an acid rough taste; it produces no change in the solutions of the salts of silver, iron, or mercury, but precipitates those of copper, of a green colour.

STRYCHNOS (from στρύχνος), a name applied by Theophrastus and Dioscorides to a kind of nightshade, and adopted by Linnæus for a genus of plants belonging to the natural order Apocynaceæ. This genus has been made the type of a distinct order by Blume, who has been followed by Link, D. Don, and others. The principal difference that it presents from the order Apocynaceæ, to which it is referred by Von Martius, Brown, and Lindley, is in its peltate seeds and simple succulent fruit. This genus is composed of trees or shrubs, which do not yield a milky juice, and have opposite usually nerved leaves and corymbose flowers; some of the species are possessed of tendrils, and are climbing plants. The calyx is 5-parted; corolla tubular, funnel-shaped, with a 5-parted spreading limb, which is valvate in æstivation; the stamens are 5, inserted into the throat of the corolla; ovary 2-celled, with a single style and capitate stigma; fruit a berry, pulpy inside, with a hard rind: seeds peltate, numerous, attached to a central placenta, with copious albumen, and foliaceous embryo. The species are not numerous, and are found principally in the tropical parts of Asia and America. One has been described by Mr. Brown a native of New Holland.

Strychnos Nux-vomica, Poison-nut or Ratsbane, is characterised by its oval shining leaves 3-5 nerved, and its round smooth berries containing many seeds. The flowers are small, and of a greenish-white colour, and are arranged in terminal corymbs. The fruit, when ripe, is of the size and colour of an orange. Although the seeds of this plant yield an alkaloid, which is a deadly poison, the pulp of the fruit is greedily eaten by many kinds of birds. The wood of this plant is very hard and durable, and on that account is applied to many purposes by the natives on the coast of Coromandel and other places where it grows. For the medical properties of this plant, see the article on that subject.

S. potatorum, Clearing-Nut, has ovate or oval glabrous pointed leaves; a deeply fissured bark, and berries containing only one seed. It is an abundant plant in the woods and mountains of the East Indies. It has shining fruit, which is black when ripe. When full grown, it attains a height of from 15 to 20 feet, and, like the last species, has a very hard wood, which is used for various economical purposes. The English name is derived from the use which is made of the seeds, which, when dried, are sold by the natives for the purposes of clearing muddy water.

S. St. Ignatii, St. Ignatius's Bean, has ovate acute glabrous leaves; pyriform fruit with many seeds, and 1-flowered axillary peduncles. It is a climbing shrub, without tendrils, bearing long drooping white flowers, which have the scent of jasmine. This species is the *Ignatia amara* of Linnæus, but has been referred to the present genus by later botanists. It is a native of Cochin-China, the Philippine Islands, and other parts of Asia. This plant is called *Papeeta* in India, and is used by the native doctors as a remedy in cholera, but is administered in conjunction with Jehiree (*Cocos Maldirica*). When given in overdoses, the symptoms are those of poisoning by strychnia, as vertigo, convulsions, &c., and the remedy used for these effects is lemonade in large quantities, which is said to afford relief speedily.

S. colubrina, Snake-wood, or Snake-poison Nut, is a climbing plant with simple tendrils; leaves oblong or oval obtuse, 3-nerved, shining; ovaries many-seeded. It is a native of the coast of Coromandel and of Silhet. It has small greenish-yellow flowers, and fruit as large as an orange, of a yellowish colour. It is called by the Telingas *Naga Musadi*, and is considered by the Indian doctors as an effectual remedy for the bite of the *Naga* or *Cobra de Capella*, a well-known poisonous snake. For this purpose it is used both externally and internally. It should however be stated as the result of the observation of the most intelligent travellers, that these vegetable remedies are not to be depended on in cases of bites of serpents, and that where danger is apprehended, the only effectual remedy is excising the wound. The wood of this and other species of the genus is brought to this country, and known under the name *Lignum colubrinum*.

S. Tieute, Tjettek or Upas Tieute, has elliptical, acuminate, 3-nerved, glabrous leaves, and simple tendrils, which are thickened opposite the solitary leaves. This plant is a climbing shrub, and is a native of Java, and is said to be the true Upas-tree of that country. It is undoubtedly the most poisonous species of the genus, and yields the greatest quantity of strychnia. There are several other plants which are called by the name of Upas in various parts of Asia. The natives of Java prepare from this species one of the most deadly of the various poisons that are used by barbarous nations, for producing death by the wounds occasioned by their arrows.

S. toxifera, Wooraly, *Urari*, or Poison-plant of Guiana, has a climbing stem, thickly covered with long spreading reddish hairs; coarse, rough, 5-nerved, ovate, or oblong, shortly acuminate leaves; large round fruit. This plant is a native of Guiana, and was lately brought to this country by Mr. Schomburgk. It had long been suspected that the poison used by the American Indians for their arrows was a species of Strychnos, but such is the secrecy with which they gather the plant and prepare the poison, that all inquiries had been frustrated. Mr. Schomburgk's long stay in Guiana has enabled him to decide this point: by bribing some of the natives, he induced them to guide him to a spot where their famous Urari flourished, and on arriving at the place, found it to be the species of Strychnos above described. In the preparation of the poison, the Urari is not the only ingredient, but forms about half of the bulk of the ingredients used. For a full account of the discovery of this plant, and the mode of making the poison, with its effects on the animal economy, the reader is referred to Mr. Schomburgk's account of the Indian arrow-poison.

(*Annals of Natural History*, vol. vii., p. 407.) It is remarkable that the poison prepared from this plant, though destroying life so rapidly when applied to a wound, may be taken into the stomach in doses of several grains without producing any ill effects, and it has even been proposed as a remedy in many diseases. It must be admitted however that it is a dangerous remedy to administer, as by coming in contact with the slightest abrasion of surface or ulceration, it might immediately destroy life.

S. pseudo-quina, Quina do Campo, has short-stalked, ovate, quintupled-nerved leaves, which are callous at the edge and smooth, or nearly so, above. It is a native of Brazil, and forms a scrubby plant about 12 feet high, with a corky bark. Its fruit is a smooth shining berry of a yellow colour, containing only four seeds. This plant is not poisonous, and is remarkable for its bitterness, which gives it a resemblance to the gentians and cinchonas. The fruit of this species is eaten by the native children. The fruit also of a species, *S. brachiata*, is eaten by deer in Peru, and that of *S. spinosa*, a Malagash plant, is greedily devoured by swine.

STRYCHNOS NUX-VO'MICA, *Medical Properties of.* The genus Strychnos, consisting of about twelve species, is remarkable for containing among these some which possess only mild or beneficent properties, while others are endowed with more potent and destructive powers than almost any other members of the vegetable kingdom. This extraordinary difference is presumed to be owing to certain species containing only an extractive, which is tonic and febrifuge, while others contain one or two alkaloids, which are extremely poisonous. This is true as far as the S. Nux-vomica, S. Ignatia, S. Colubrina, and S. Tieuté are concerned, all of which contain either *Strychnia* or *Brucia*, and some both of these alkaloids; but it does not apply to the S. toxifera (Schomburgk), in which no alkaloid has been detected. It must be admitted however that the S. toxifera, though equally fatal with the others, produces death in a different way. Those possessed of an alkaloid destroy life by exciting *tetanic spasms*, while the *wourali*, or *worary*, or [illegible] (prepared from the S. toxifera), produces diametrically opposite effects, as the muscles of voluntary motion are *paralysed* by it. The only species strictly officinal is the *nux-vomica*, *poison-nut*, or *ratsbane*, of which the seeds are employed, and to this attention shall be at present confined.

Strychnos Nux-vomica is a native of Coromandel, Malabar, Ceylon, and other parts of India, growing in sandy places, and attaining the size of a tree, but short, crooked, and sometimes twelve feet in circumference, flowering in the rainy season. The fruit is about the size of a St. Michael's orange, with a bitter astringent pulp, and containing (according to Sir Whitelaw Ainslie) from three to five seeds. The pulp may be eaten, but the seeds are poisonous and officinal; each seed is flattish, or very slightly concave on the side of the umbilicus, convex on the other, thickened at the margin, peltate, about three lines in thickness, and clothed with dense greyish, silky, or velvety hairs, which towards the umbilicus are arranged in concentric circles. The testa or coat is thin, the nucleus white or greyish, hard, horny, or cartilaginous, bipartite or divided by a cavity in the centre: the embryo is near the margin of the seed, and its position is often indicated by a prominent point.

Owing to the hard cartilaginous nature of the seeds, they are extremely difficult to reduce to powder or to slice. Different expedients are adopted to accomplish this. They may be exposed to the vapour of boiling water for two hours, then chopped or sliced, afterwards dried rapidly, and ground in a mill; or they may be boiled in an iron kettle with a small quantity of water, then dried and pounded; or merely steeped in water, sliced very fine, and then dried and pounded. Merck boils them in a close vessel for twenty-four or thirty-six hours with dilute sulphuric acid, by which they are completely softened. The mortar in which they are pounded, or the mill, should be kept covered, as the dust ascending may prove deleterious if inhaled. Old or mouldy seeds should be rejected, and consigned to the fire, but not thrown out, as they are destructive to pigs and other animals. Their freshness and excellence may be judged of from the whiteness of the interior when sliced. The entire seed is devoid of odour, but the powder has a peculiar one, somewhat resembling liquorice: the taste is nauseously bitter. Nux-vomica should never be purchased in the state of powder, as it is frequently adulterated with common salt or even emery-powder.

In Tobago an oil is expressed from the fresh seeds, which is used for burning.

The best analysis of the seeds of nux-vomica is by Pelletier and Caventou (*Annales De Chimie et Physique*, x., p. 142), who found—

Strychnate (or igasurate) of strychnia, 0·4 per cent.; strychnate of brucia; wax; concrete oil; yellow colouring-matter; gum; starch; bassorin; woody fibre; carbonate of lime and chloride of potassium, in the ashes.

It is on the strychnate of strychnia, and, in a less degree, on that of brucia, that the active properties of nux-vomica depend. Strychnia can be separated and purified by the process given above. [STRYCHNIA.]

Five pounds of the seeds yield sixteen ounces of a watery extract, and ten ounces of an alcoholic extract, which however always contains some green concrete oil soluble in æther.

Nux-vomica seems to exert a deleterious influence alike over vegetables and animals; there is however a difference of susceptibility to its action in different classes of animals, since a much larger quantity is necessary to destroy herbivorous than carnivorous animals.

The degree of effect varies with the quantity employed, but it seems to be the same in kind, being confined to the ganglionic system of nerves and the spinal chord, extending as high up as the medulla oblongata, and, according to Flourens, influencing even the cerebellum, but certainly not directly affecting the cerebrum. Hence in fatal cases the intellect is not disturbed till the extinction of life. The decapitation of animals does not hinder the characteristic action of nux-vomica, while, on the opposite hand, the removal of the spinal-marrow completely prevents its peculiar agency, even though artificial respiration be maintained. From some experiments of Segalas, it appears also to exhaust the irritability of the heart; for in animals he found that organ could not be stimulated to contract after death, and life could not be prolonged by artificial breathing. Nux-vomica differs from all narcotic poisons, by not exhausting the sensibility. During the intervals of the fits the sensibility is on the contrary heightened, and the faculties acute.' (Christison.)

Three distinct degrees of action may be observed from the use of nux-vomica. In small doses the ganglionic system appears chiefly to be affected, and this so slightly, that any phenomena are observed only in cases of disease, particularly in hysterical and weak persons. The secretions are increased, both of the intestinal canal, the liver, the kidneys, and of the skin, accompanied with an increase of appetite and improved digestion.

It is in the second degree of action that the characteristic effects of nux-vomica begin to appear. The patient experiences a feeling of weight and weakness in the movements of the limbs, inducing him to remain at rest: while his mind is restless, sad, depressed, and anxious for solitude and darkness, as he is peculiarly sensitive to light, noise, or the movement of the surrounding objects. With an augmentation of the dose, these phenomena are increased, and the contact of any external body causes a feeling like an electric shock, the voluntary muscles are no longer under the control of the will, and the individual staggers on the least attempt at walking. At the beginning of these occurrences the pulse is hard and quickened; the gums, cheeks, and eyes reddened, and the respiration more frequent; but when the nervous system is more affected, the hardness of the pulse subsides, the countenance becomes of an ashy paleness, the eyes appear sunken, articulation is difficult and indistinct, breathing is laborious, and accompanied with violent spasms of the larynx, and the other muscles of respiration are irregular in their action. After these symptoms have lasted six or twelve hours, they subside, and a great increase of the secretions is observed to follow; itching of the skin, with much perspiration, even accompanied with an eruption of vesicles or large blebs: the secretions of the serous membranes, of the kidneys, and of the mucous membranes, are sensibly increased, those of the latter sometimes becoming bloody. During this period the patient complains of heat in the stomach and throat, of thirst, of foul taste, and rancid eructations, with nausea, and occasionally even vomiting. While the augmented secretions are taking place, the more prominent nervous symptoms disappear: and in a few days the sufferers recover entirely from the debility and excessive sensibility.

The third degree of action manifests itself by tetanus and

asphyxia, occurring in single paroxysms, alternating with paralytic torpor. The paroxysms become longer, and the remissions shorter, in which however, till death close the scene, the intellect remains unaffected. While the voluntary muscles are entirely withdrawn from the control of the will, the pulse sinks and becomes slower, the breathing more and more laborious ('the external muscles of the chest may be felt during the fits as hard almost as bone; and, according to an experiment of Wepfer, the diaphragm partakes of the spasm of the external muscles:' Christison). The belly swells and exhibits blue marks, the countenance is livid, and in a paroxysm of tetanic rigidity the breathing ceases, though the heart's action and the peristaltic motion of the intestines continue for some time; and, if an artery be opened, black carbonaceous blood issues. 'Death however does not always take place by tetanus: in some cases the departure of the convulsions has been followed by a fatal state of general and indescribable exhaustion.' (Christison.) Thus after the spasms have lasted twelve, sixteen, or twenty-four hours, and completely disappeared, the individual has nevertheless died, after being apparently in a state of safety. This has been ascribed to the depressing effect on the heart's action, through the medium of the nervous system, of long continued pain (Alison's *Pathology*); or more probably, according to Dr. Marshall Hall (*Diseases of the Nervous System*, and *Gulstonian Lectures*), to what he terms *secondary asphyxia*. Or the individual may suffer an attack, after the primary symptoms have subsided, of inflammation of the stomach and intestines, which may or may not prove fatal.

Vomiting does not always occur, though the name would seem to imply the frequency of this symptom.

Nux-vomica is important not only for its formidable properties, but for the illustrations it furnishes to certain physiological doctrines. Thus when used in cases where a portion only of the body is paralysed, it excites convulsions in the paralysed part before any action be observed in the sound parts. 'The paralysed parts are the seat of tetanic shocks, of a prickly sensation, and of a perspiration, which is not observed elsewhere. In hemiplegia the sound side of the body remains tranquil, while the affected one is the seat of extreme agitation: the tetanic attacks succeed each other rapidly, and an abundant exudation takes place. Even an anomalous eruption has been observed, while the healthy side has been perfectly free. One side of the tongue is sometimes sensible of a decidedly bitter taste, which is not perceptible on the other. If the dose be augmented, both sides become the seat of tetanic action, though not equally so.' (Magendie.) It is also very remarkable that the contact of any external body with any part of the frame of an individual under the influence of nux-vomica which is supplied with nerves originating from the spinal chord, immediately excites convulsive actions. It is thus thought to support the notion of a distinct or *reflex function* of the spinal chord. (Marshall Hall's *Lectures on the Nervous System*: Grainger, *On the Spinal Chord*.) Certain it is that in persons poisoned by nux-vomica, whether the seeds or bark (false Angustura bark), the mere act of touching the skin to feel the pulse has excited again the convulsive motions. Of these two phenomena, viz. the action of strychnia on the paralysed limbs previous to causing any obvious effect on the sound organs, and of the contact of an extraneous body exciting the tetanic throes, the following explanation has been given by Mr. Grainger:—'Strychnia acts by preference on the paralytic limb or limbs, because the cerebral control is removed from the paralysed limb. If the chord be divided, the pure spinal power remaining, when the skin is touched the limb is retracted, and must be retracted, because the cerebral control is wanting. So when the spinal chord is stimulated by strychnia, it must act on the limb or limbs from which the cerebral power is withdrawn.'

Nux-vomica acts most rapidly when introduced into a vein, and in other instances in the ratio of the absorbing power of the part; but it produces no effect when applied directly to a nerve or to the brain.

In fatal cases the morbid appearances vary according to the period at which death occurs. When death results from asphyxia, the brain is gorged with blood, and the texture softer than natural. When death takes place at a late period, sometimes appearances of inflammation are found in the stomach and intestines; but frequently these are absent. A tetanic stiffness remains in the corpse, till decay commences: this state of rigidity however does not invariably occur.

The powerful properties of nux-vomica, and the rapidity of its action when administered in the state of a pure alcaloid, strychnia, or its salts, have deterred medical men from making so extensive a use of it as its therapeutic qualities entitle it to. The necessity for care in its administration is manifest from the facts, that death resulted, in one instance, merely from a woman grating cheese with a file which had been previously used to rasp seeds of nux-vomica; and in another instance, death ensued from three grains of the alcoholic extract taken at once. The consequence of a salutary dread of its being entertained has been that it is generally employed only as a last resource, instead of being used at an earlier period. It might however be beneficially used, with due caution and careful superintendence, in many cases of hysteria and hypochondriasis, dependent on irregular action of the nerves of the ganglionic system. In cases of hysterical paralysis, accompanied with greatly impaired sensibility, it would be more influential than any other agent in a disease at once tedious and distressing.

In paralysis it has been found more uniformly beneficial than most other remedies, though success has not always attended its employment. It is certainly better suited for some forms of paralysis than for others.

It is most serviceable in cases of paralysis of parts which derive their nerves from the ganglionic system or spinal chord. Hence it is more serviceable in *paraplegia* than in hemiplegia, in palsy of the bladder, of the rectum, and even in some cases of chronic diarrhœa dependent on atony of the intestines. It is more serviceable in the palsies which follow fevers, rheumatisms, repelled eruptions, habitual drunkenness, and exposure to noxious metals, such as lead or mercury, and merely depressed nervous power, than in those which result from effusion of blood. (See Dr. Bardsley's *Hospital Facts*.) Its use is altogether improper immediately after an apoplectic seizure and indeed whenever vascular fulness or organic disease of the brain is supposed to exist. Though less useful in affections of the nerves which arise from the brain, it has nevertheless proved beneficial in some cases of amaurosis, in which the endermic method of application has been employed, rather than the internal administration of it. Deafness has also been cured by it.

In the Asiatic or epidemic cholera it was of unquestionable service, though its use was generally postponed till a very late stage of the disease, instead of being employed at the commencement, when the premonitory diarrhœa could easily have been checked by it. When employed in paralysis of any of the limbs, an auspicious sign of its beneficial influence is a feeling of formication, and often of sweating, with or without an eruption, and spasmodic twitchings in the limb, while the rest of the body is unaffected.

Though nux-vomica is not, strictly speaking, a cumulative poison, yet it is prudent to suspend the use of it now and then, and upon resuming the employment of it, to return to a small dose, and not employ such a quantity as the patient had already taken; for it must be borne in mind that a person who has once been under its influence is more easily affected than a person using it for the first time.

It was conjectured by Batka, and it has since been proved by Dr. O'Shaughnessy, that the false Angustura bark [GALIPEA] was the bark of the Strychnos nux-vomica, so that in case of poisoning by that article, the same mode of treatment is to be pursued as in poisoning by nux-vomica or strychnia.

In cases of poisoning by nux-vomica, the most prompt treatment is necessary, and still more so if any of the soluble salts of strychnia shall have been taken. 'Nux-vomica is occasionally made the instrument of voluntary death, although no poison causes such torture.' (Christison.) The stomach-pump should instantly be had recourse to, when nux-vomica has been taken in powder, and as it adheres very obstinately to the coat of the stomach, it must be perseveringly used, with plenty of water. Emetics are too tedious in their action to be depended upon. M. Donné has recommended, when strychnia or any of its salts have been taken, to endeavour to form an insoluble salt; and for this purpose proposes chlorine, bromine, or iodine. The tincture of iodine may be procured promptly, but if ten minutes elapse before it be administered, it is unavailing. When the quantity of strychnia taken is not large, nor the symp-

toms very urgent, vital stimulants or sedatives are often sufficient, and for this purpose wine, brandy, or a mixture of acetous æther and laudanum, or laudanum alone, will remove the present danger. Conium or its tincture offers probable means of antagonising the action of strychnia, as suggested by Dr. Pereira. It is said that the leaves of the Feuillea cordifolia furnish an antidote to nux-vomica and several other vegetable poisons. It must ever be remembered that the danger is not entirely removed, though the spasms may have subsided, and the respiration become easy. Inflammation of the stomach may supervene, which will require the usual treatment, or secondary asphyxia may steal on, and destroy the patient. To prevent this last occurrence, great watchfulness is necessary, especially during the night, and the patient should be frequently awakened, and made to drink freely of green tea. But perhaps the most potent and efficient antidote to the other poisonous strychnias would be the urari poison of South America, as suggested by Mr. Morgan. (See Morgan's *Lecture on Tetanus*, p. 31.) The preparation of this substance, which has been an object of curiosity and interest since the time of Sir Walter Raleigh, has been fully detailed by Mr. Schomburgk. (*Annals of Natural History*, vol. vii.) It is an article of much importance to the natives of Guiana, as much of their means of subsistence depends upon their possessing this poison, in which to dip their arrows for the chase. They employ much mystery in its preparation, and pride themselves on its valuable properties, preferring it, with some show of reason, to gunpowder. 'I know,' said the *amo del curare* (master of poison, or Indian, who knows how to prepare it), 'that the whites have the secret of fabricating soap, and that black powder which has the defect of making a noise, and killing animals when they are wanted. The *curare*, which we prepare from father to son, is superior to anything you can make *down yonder* (beyond sea). It is the juice of an herb, which kills *silently* (without any one knowing whence the stroke comes).' (Humboldt, *Personal Narrative*, 2nd edit., vol. v., p. 517.) The chief if not the only active ingredient is the Strychnos toxifera (Schomb.), and perhaps, in some places, Strychnos cogens (Bentham), the other ingredients (most of which are obtained from climbing plants, lianes, or 'nebbees,' except one bulbous plant, a cissus, and another supposed to belong to the Xanthoxyleæ) are used only to bring the juice to a proper degree of consistency and adhesiveness. Arrows dipped in it have been known to retain their poisonous properties for twenty-seven years. (Iliff, in *Medical Gazette*, vol. xx., p. 261.) The poison when inspissated may be rendered liquid by heat, and is soluble in water, in alcohol, in hydrochloric acid, and in volatile alkaline spirit. It unites with acids without emotion or change of colour. If it be united with alkalis, no ebullition is observable, but it changes its colour from a dark-brown to a yellowish-brown. It possesses a remarkable influence over the blood, after it is taken from a vein. 'A few grains, mixed with as many ounces of human blood, warm from the veins, entirely prevents a separation of serum and crassamentum, and the whole mass continues in a state of fluidity similar to that in which it was drawn, until, after some days, it putrifies.' (Bancroft.) This property seems to point out the propriety of employing it in cholera, in which the separation of the serum from the crassamentum, while the blood was yet in the body, was one of the most remarkable symptoms of that disease. Dr. Hancock is of opinion that it is one of the most potent sedatives in nature, and, could it be safely managed, he had no doubt it might become a valuable remedial agent in the treatment of spasmodic or convulsive disorders. That there are means of controlling its action he was fully persuaded: and such, it appears, are adopted by the Indians of the Rio Negro and Amazon, who were constantly in the habit of shooting monkeys, birds, &c., and after bringing them to the ground, they took means to resuscitate them, and thus carry on a profitable trade with Grand Para and the Brazils. (*Medical Gazette*, vol. xx., p. 281.) The flesh of animals, birds, or fish which have been killed by these poisoned arrows, possesses no deleterious properties when eaten, but is thought to be more delicate than when killed by other means. Like the poison of the viper, which is only noxious when inserted into a wound, and which may be swallowed with impunity, the urari may be taken into the stomach with perfect safety. Its taste is an agreeable bitter, and it has a tonic and febrifuge effect, frequently proving a valuable cure in intermittents. It, as well as the venom of the viper, seems to be disarmed of its virulence by undergoing the process of digestion.

When inserted into a wound, shortly after a quantity of the 'tshittick' poison, prepared in Java from the Strychnos Tieuté (Upas Tieuté; see Sir Stamford Raffles's *History of Java*: Dr. Horsfield's *Plantæ Javanicæ Rariores*, part i., and *Annales de Chimie*, vol. xxvi.), it completely stills the convulsions excited by that active agent. (See Morgan's *Lecture on Tetanus*.) As the urari acts upon the brain, producing simple suspension of its functions, and a state of asphyxia by artificial respiration, this state may be recovered from, if the dose has not been too strong, and other circumstances are favourable. (See Brodie, in *Philos. Trans.*, vols. ci. and cii.)

The tshittick poison contains strychnia only, unaccompanied by brucia, and is therefore more rapid in its action than any other strychnos.

On account of the difficulty of preparing the alcoholic extract of nux-vomica of uniform strength, strychnia, or some of its soluble salts, is now generally substituted for it, as these admit of easy subdivision of the dose. Sulphate of strychnia has been used in some cases with great advantage (See Gaskoin, in *Med. Gaz.*, vol. x., p. 316); so also the acetate: but a form of preparation which has proved of service in some long-standing and almost hopeless cases of paralysis, is the hydriodate of strychnia. (See Magendie, *Formulaire*, 8ième edit., p. 144.)

Care must be taken that the strychnia be pure, as a spurious article is vended in France, which contains no trace of strychnia. Bichloride of mercury is a good test for strychnia, but it causes no precipitate from the solution of the acetate of strychnia; but the addition of hydrochloric acid causes a white crystalline precipitate. Sulpho-cyanodide of potassium appears to be the best test for strychnia. (See *British Annals of Medicine*, vol. i., p. 190.)

Strychnia is prepared either from the nux-vomica seeds, in which case it is difficult and expensive to separate it from the brucia, or it is obtained from the St. Ignatius Bean, in which it exists in about three times larger quantity than in nux-vomica. It is also, but rarely, procured from the Strychnos Colubrina. The purest and most easily obtained is furnished by the Strychnos Tieuté, but the rarety of this substance is a practical obstacle to its employment.

Snake-wood. Many substances, in countries infested with serpents, are reputed to be efficacious in counteracting the poisonous bites of these reptiles; one of the most celebrated of these is the root of the Strychnos Colubrina. The strychnia probably acts as an antagonist to the stupifying effects of the poison of the snake, just as arsenic does to the poison of the Coluber carinatus of the West Indies. [ARSENIC.]

Strychnos Potatorum, called also S. Tettan Cottay, or Clearing-nut, is a native of India, and is a larger tree than any other species. It is devoid of noxious properties. The fruit, though when very young it is made into a preserve, and eaten, is reckoned emetic by the native doctors. The chief use made of it is to rub the seeds hard for a short time round the inside of an earthen pot, into which water is poured, and in a short time it becomes clear, tasteless, and wholesome, however muddy, brackish, or putrid it may have been: hence its name of clearing-nut. Officers and soldiers, before setting off on a march, provide themselves with a store of these, as water purified by such means is deemed more wholesome than that clarified by alum. The bitter is in this case probably of use, as the inhabitants of Cairo render the muddy waters of the Nile quite clear and drinkable by rubbing bitter almonds on the inside of the earthen jars in which the water is kept. (Niebuhr's *Travels*, vol. i., pp. 71, 72.)

Strychnos Pseudo-china, Quina do Campo, or Field China, is a native of Brazil (St. Hilaire, *Plantes Usuelles de Bresil*, t. 1), and is devoid of strychnia or brucia. It is a remedy of the Sertaneias, being peculiarly fitted for those cases to which the true cinchonas are unsuitable. The taste is at first faintly aromatic, then astringent, and at last slightly bitter. It has no odour. In its properties it resembles Quassia, Menyanthes, or Gentian more than the true cinchonas with none of which, except the Maracaibo bark, could it readily be confounded in its physical characters. Mr. Burchell says, however, that even in the proper localities of the cinchonas many strychni are collected. [CINCHONA.]

STRYGOCEPHALUS. [Brachiopoda, vol. v., p. 312.]

STRYMON. [Amphipolis: Macedonia.]

STRYPE, THE REV. JOHN, is said to have been of German descent, but he was born in London, 12th November, 1643. After having been six years at St. Paul's school, he was admitted, in 1661, of Jesus College, Cambridge: but he soon after removed to Catherine Hall, where he took his Bachelor's degree in 1665, and his Master's in 1669. In the latter year he was presented to the perpetual curacy of Theydon-Boys in Essex; which however he resigned a few months after, upon being appointed minister of Low Leyton in the same county. Here he continued to reside till within a few years of his death, when he came to live with Mr. Harris, an apothecary at Hackney, who had married his granddaughter. He had been lecturer of Hackney till he resigned that appointment about the year 1724; and he also held along with his Essex living the sinecure of Terring in Sussex, to which he was presented by Archbishop Tennison. He died 13th December, 1737, in the house of Mr. Harris, at the great age of ninety-four.

The history of Strype's long life, in so far at least as it is of any public interest, consists merely of the list of his successive publications. Although his works amount to thirteen large folio volumes, besides octavos and pamphlets, it was not till he had reached his forty-sixth year that he gave any employment to the press, and then he began with a single sermon: nor did he print anything more till five years after. Then, in 1694, appeared, in a folio volume, the first fruit of his researches in ecclesiastical antiquities, his 'Memorials of the most renowned Father in God Thomas Cranmer, sometime Lord Archbishop of Canterbury.' This was followed, in 1698, by an octavo volume entitled 'The Life of the Learned Sir Thomas Smith, principal Secretary of State to Edward VI. and Elizabeth; wherein are discovered many singular matters relating to the State of Learning, the Reformation of Religion, and the Transactions of the Kingdom during his time;' that in 1701 by another octavo volume entitled 'Historical Collections relating to the Life and Acts of Bishop Aylmer' (or Aelmer, who filled the see of London from 1577 to 1594); and that by his 'Life of Sir John Cheke,' 8vo., London, 1705. He published another single sermon in 1708; and the next year he brought out the first volume in folio of his 'Annals of the Reformation and Establishment of Religion,' comprehending the first twelve years of the reign of Elizabeth. Before proceeding further with this work, he produced three more biographical folios as companions to his Life of Cranmer: his 'History of the Life and Acts of Archbishop Grindal,' in 1710; his 'Life and Acts of Archbishop Parker,' in 1711; and his 'Life and Acts of Archbishop Whitgift,' in 1718. Then, digressing to another field of antiquarian investigation, he came forth, in 1720, with his new edition of Stow's 'Survey of London,' in two bulky folios, of which we may safely say that nearly three-fourths consist of his own additions. [Stow.] The next year, 1721, was published what may be regarded as his most important work, his 'Ecclesiastical Memorials, relating chiefly to Religion and the Reformation of it, and the Emergencies of the Church of England, under King Henry VIII., King Edward VI., and Queen Mary I.' in three volumes, folio. Of this work a new edition, though limited, we believe, to a very small number of copies, was brought out at London in 1816, in seven volumes, 8vo. But Strype's labours were not yet closed: another single sermon, in 1724, ushered in a second edition of the first volume of his 'Annals' in 1725; a second folio volume of that work the same year, bringing down the history of the Church of England to A.D. 1580; a third in 1728, embracing the period from 1581 to 1588; and a fourth, in 1731, consisting however only of a collection of papers, which the author's advanced years and infirmities prevented him from reducing into a narrative, in illustration of the remainder of the reign of Elizabeth.

Strype probably spent the first fifty years of his life in collecting the materials of the voluminous works which he gave to the world in the succeeding forty. His books all consist for the greater part of masses of original papers, even so much of them as has the form of being his own composition scarcely ever evincing any real digestion of the facts which he sets before his readers. He claims the merit of great fidelity and accuracy, and probably he may be trusted in general for the correctness of his transcriptions, all of which he professes to have made with his own hand; but, being really what may be called a dull, almost a stupid man, though possessed of a considerable amount of knowledge, he is both apt to miss the essence of events and transactions in his prolix detail of the circumstances, and even occasionally, with all his tediousness, to leave his narrative imperfect by the omission of some particulars which would not have escaped a sharper intellect. We believe every reader or consulter of Strype will have found himself annoyed occasionally by this absence, amid a multitude of superfluities, of the one thing needful. His books however are all curious and valuable for the quantity of information they contain never before published, and not to be elsewhere found; and they must on that account be considered as forming, along with Burnet's 'History,' and even in some respects in a higher degree than that, the foundations of the history of the reformed Anglican church.

STUART FAMILY. The origin of this family is briefly stated under Robert II. of Scotland; and the list of kings of Scotland of this family, from Robert II. of Scotland to James VI. of Scotland and I. of England, is given in the article Scotland. The Acts of Settlement, passed in the reign of William III., secured the succession of the House of Hanover to the throne of England, and the descendants of James II. were subsequently excluded from the throne of Scotland also. [George I.] The chief historical interest that attaches to the House of Stuart after the abdication of James II., is limited to the two invasions of Great Britain by his son and grandson, who are often respectively called the elder and younger Pretender.

Stuart, James Francis Edward. On the 16th of September, 1701, James II. died: and his son James, Prince of Wales, was immediately acknowledged by Louis XIV. as king of Great Britain, contrary to his promise to King William. The king of France was induced, as Tindal affirms, to take this step, chiefly by the persuasion of Madame de Maintenon, whom Mary of Este had engaged in her favour; and the influence of the Dauphin was added to that of Madame de Maintenon. The king of Spain, the pope, and the duke of Savoy also acknowledged the Pretender, as the Prince of Wales was afterwards called, as king of England.

In 1708 extraordinary preparations were made by Louis XIV. at Dunkirk, but the object of them was kept so secret, that no one in England suspected the intentions of the French. Louis, indignant at the recent attempt of the allied powers upon Toulon, and believing that the discontent of the Scotch with the Union rendered them ready for revolt, was preparing to invade England. The Pretender's claims were the ostensible reason for this attempt; and Louis, in a visit to him at St. Germain's, presented him with a sword mounted with diamonds, begging him never to forget that it was a French sword. The prince repaired to Dunkirk, intending to pass over to the Frith of Forth; but he was taken ill of the measles, and the English fleet had time to get ready. 'In the meantime,' says Cunningham, 'the Pretender wrote to the French king for his directions what to do in this unhappy case. The French king, who was no more concerned about the Pretender's life and affairs than to serve his own turn, answered, that he must not desist from the undertaking nor delay his embarkation; and ordered some men thither to see him on ship-board, though he was hardly recovered of his distemper.' So eager was Louis for the enterprise, that though the Pretender requested only a few days for the recovery of his health, Louis was peremptory, and the fleet put to sea. But this expedition was wholly unsuccessful, partly, as some thought, from the aversion of the Pretender to land in Scotland, partly from storms, which dispersed the French ships, partly from the vigilance of the English admiral, Sir George Byng, but chiefly from the dissensions of Fourbin and Gare, who had the command of the French fleet. It returned, with the Pretender on board, to Dunkirk, and the disappointed prince obtained permission of Louis to engage in the campaign in Flanders. In commemoration of this expedition a medal was struck in England; and the price of 100,000 crowns was set upon the Pretender's head by the English parliament. On the 11th of July, 1708, the Pretender is stated by French writers to have been in the battle of Oudenarde, which was gained by Marlborough; but according to the accounts of Dutch historians, he contented himself with observing the engagement from the steeple of a neighbouring village, and consulted his safety by a timely retreat.

In 1713 the Pretender published a protest which he forwarded to the ministers of the different states at Utrecht,

claring that he could not 'by his silence seem to consent what was transacting to the prejudice of him and of the wful heirs of his kingdom;' and that, finding the confede-te powers had no regard to his rights, he solemnly pro-sted against all that might be agreed on to his prejudice. o notice was publicly taken of this protest; but the Pre-nder's friends in England were indefatigable in strength-ning his favour with the queen. The jealousy which Anne erished of the House of Hanover, and her resentment hen it was proposed that the Electress Sophia should re-de in England, strengthened for a time the influence of ord Bolingbroke. But the Pretender's stronghold was the affections of the queen. It has even been surmised hat she was cognizant of the expedition against Scot-and in 1708. Upon the death of Queen Anne, James, ho had been residing at Bar-le-duc, posted to Versailles, where he met with an ungenerous reception from Louis XIV., who had found it most consonant with his in-erests to acknowledge King George I., and who intimated o the Pretender, through the Marquis de Torcy, that he must quit France. In August, 1714, James sent to the rincipal nobility of Great Britain a declaration in which e asserted his claim to the throne, and stated his surprise hat upon the death of the queen a foreign prince should ave been proclaimed king. This manifesto was sent by many of those who received it to the secretary of state; and the ambassador of the duke of Lorraine, in whose territory James was then living, was forbidden the court. A pro-clamation was made, in which the price of 100,000*l.* was set on the head of the Pretender, who, as his partisans ex-pressed it, had 'no place left for him to flee unto.' Cir-cumstances however had been operating in favour of the Pretender. Many persons had an hereditary attachment to the House of Stuart; some were influenced by hopes and promises of honours; and more, by the outcry that the church was in danger under the Whig government, which was 'the main artifice' of the plot, as George I., in his speech to parliament, after the rebellion had commenced, expressed himself. In 1715 the court of St. James's received in-formation that an open rebellion had broken out in Scot-land, headed by the earl of Mar, who had been secretary of state for Scotland when Anne died, and had been one of the first to swear allegiance to her successor. The mar-quisses of Huntley and Tullibardine, the earls of Southesk and Marischal, with many other noblemen and landed pro-prietors, joined in the rebellion, and the Pretender's stan-dard was set up by the earl of Mar at Brae-Mar, on the 6th of September, 1715.

Active measures were taken by the English government. Several suspected persons were imprisoned in the castle of Edinburgh; and General Whetham was ordered to form a camp near Stirling. Several vessels at the same time sailed from Hâvre-de-Grace for Scotland, and notwithstanding the efforts of the British navy, one of them reached Ar-broath, and supplied the Highlanders with arms and am-munition, which were carried to Brae-Mar. Assurances were also given that the Pretender would shortly arrive. But the news that Louis XIV., who had secretly encouraged the rebellion, was dead, struck a panic among the Jacobites, and for a time suspended their operations. They decided however to proceed in their course, and to urge the Preten-der by letter to appear amongst them. The earl of Mar as-sumed the title of lieutenant-general of the Pretender's forces, and a manifesto, setting forth the national grievances, was published. A scheme was also formed to surprise the castle of Edinburgh, but was defeated.

About the 9th of September the duke of Argyle, com-mander-in chief of the English forces in Scotland, marched northward; whilst several Scottish peers, the earl of Su-therland, the duke of Roxburgh, and others, showed their loyalty to King George by raising their clans. A con-spiracy was about the same time discovered in England. Colonel Paul, who had a company in the first regiment of foot-guards, was detected in enlisting men for the Pre-tender's service. In Somersetshire an insurrection was projected, but checked by the government; treasonable designs however were so widely spread in the western counties of England, that at Bath the Jacobites talked openly of the Scotch rebellion as merely a diversion to draw the troops off to the north. General Wade was at last ordered to march to Bath, where he discovered and seized many chests of fire-arms and some pieces of cannon. The university of Oxford was also tainted with Jacobitism, and 'King James's' health is reported to have been drunk there every day. General Pepper being dispatched to Oxford, entered the city early one morning and apprehended six-teen or eighteen persons, whom he conveyed to Abingdon. Cornwall was also disaffected, and a correspondence was now carried on among the conspirators throughout Great Britain. As their communications could not with safety be entrusted to the post, Jacobite gentlemen rode to different parts of the kingdom under the pretence of travelling for pleasure, but in fact to convey letters and intelligence.

The next step which the insurgents took in the north was to proclaim James king at Newcastle-upon-Tyne, and to make an attempt on the town of Newcastle, but finding the gates closed, they retired to Hexham, where they were joined by some Scottish horse. Their numbers were now increased by recruits, who joined them at different towns, and the influence of the earl of Derwentwater, a Jacobite nobleman, gave them additional strength. But the town of Newcastle stood firm, and the rebels, hearing that they were to be attacked at Hexham, withdrew from that place, having first proclaimed the Pretender. On the 12th of Oc-tober the standard of James VIII. of Scotland was set up at Moffat in Annandale, by the earl of Kenmure; and on the 19th the Scots, under Lord Kenmure, being joined by the English rebels, marched to Kelso.

In the meantime the earl of Mar proceeded to Dunkeld, where the marquis of Tullibardine, and the earl of Bread-albane, joined his troops with 2000 men. They possessed themselves of Perth, and upon this important town being gained, their force was much augmented. The rebel army now assumed a formidable appearance; being the clans-men of rich nobles and chiefs, the soldiers were well armed, and amounted to 12,000, cavalry and infantry. The rebels possessed themselves of Brunt Island, and afterwards of all the towns on the coast between their head-quarters and the mouth of the Firth of Forth. The earl of Mar next attempted to cross the Firth, and to make a descent upon the Lothians, in order to gain over the south of Scot-land. Fifteen hundred men succeeded in landing at North Berwick, Aberlady, and other places. Their next attempt was to march to Edinburgh, where they expected to be joined by the people; but the duke of Argyle sending a detach-ment to prevent their entrance into the capital, the rebels changed their course, and marched into Leith. They then retreated to Seaton House, an old castle about seven miles from Edinburgh, whence the earl of Rothes, with a com-pany of dragoons and volunteers, finding it impossible to dis-lodge them without artillery, was obliged to retire.

On the 27th of October the Highlanders at Seaton House marched southwards to Kelso, where they were joined by the English and Scottish horse from Nithsdale and Northum-berland. Mr. James Murray had arrived in Edinburgh, authorised to make liberal promises of assistance from France, and to declare that he came in the capacity of se-cretary to the Pretender. It was now expected that all com-munication would soon be cut off between the duke of Argyle and London; and the earl of Mar was strongly advised to attack Argyle before the arrival of a reinforcement of dra-goons from Ireland, which were expected.

It was now that the 6000 men guaranteed by the Dutch to be sent over to England were demanded by the British ministry, and granted by the States. Orders were issued to all the governors of seaports to examine all British sub-jects who might attempt to pass from the Continent into England; for it was thought that the Pretender, with the duke of Ormond and Viscount Bolingbroke, intended to come into the country. On the 25th of October General Carpenter set out from Newcastle for Kelso, where the Ja-cobite army lay. The Jacobite commanders proposed to pass the Tweed and attack Carpenter's troops, which were tired with marching; but ultimately the Pretender's forces marched to Jedburgh, and thence towards Dumfries, which they thought of investing. The duke of Argyle was at Stir-ling with so small a force, that unless he was soon joined by the Dutch or Irish troops, he could not save Dumfries. Every thing seemed to favour the enterprise of the Pretender, but divisions in the Jacobite council of war frustrated their plans. The earl of Wintoun, one of the insurgent leaders, opposed the siege of Dumfries, and the English officers urged a march into their own country. Confidence was thus lost, and the men daily deserted. After some loss of time the rebels marched to Brampton in Cumberland, where the Pretender was proclaimed. They then proceeded to Penrith, and thence

on the 5th of November to Appleby; next to Kendal and Kirby Lonsdale, and on the 7th to Lancaster, which they entered without opposition. They left Lancaster on the 9th day of the month, for Preston, where they were joined by a number of gentlemen and others of the Roman Catholic persuasion, a circumstance which did not satisfy the Scottish chieftains and Highlanders, who had been led to expect that their forces would be augmented by the high church party.

General Carpenter was now pursuing the Jacobites, but with his dragoons only, in order to save time. He had communicated with General Willes, at Chester; and both generals advanced in concert, to unite their strength and attack the rebels at Preston. General Willes reached Preston first, and found the town strongly barricaded. On the 12th of November Willes attacked the barricade below the church, which was gained: but the other barricades, which were flanked with Highlanders, were not carried, and the king's troops were obliged to retire that evening. On the following morning General Carpenter and his troops arrived, and the town was completely invested. The Highlanders were indeed eager to make a sally, but they were not allowed to move. A capitulation was determined on, and Colonel Oxburgh went out with a trumpet to propose terms to General Willes. All however that he could gain was a promise that, if the rebels would lay down their arms, he would not allow the soldiers to cut them to pieces, and he would give them an hour to consider of it. No terms were finally made for the Jacobites. General Carpenter entered the town on one side, and General Willes on the other; and they met the rebel troops in the middle of the town. The noblemen and chieftains were put first under guard, and then their followers. The number of the English and Scottish prisoners of all classes amounted to 1459. On the same day that Preston surrendered, the battle of Dumblane was fought between the duke of Argyle and the earl of Mar. The left wing of the rebels, though they fought bravely, was routed; and the duke of Argyle, after pursuing them to the river Allan, returned to the field, where both armies stood looking at each other; towards evening the duke drew off to Dumblane, and the enemy to Ardoch. On the same day news arrived that the pass of Inverness was gained. This important advantage was the result of treachery. Lord Lovat had delivered it to the king's troops.

The principal persons among the rebels were sent to London. On reaching Highgate, they were pinioned with cords, and not allowed to hold the reins of their horses, which were led by a foot soldier. The prisoners were conducted from Highgate to London, amid crowds of spectators, the drums playing a triumphal march. They were distributed in different prisons; the noblemen were lodged in the Tower.

On the 22nd of December the Pretender landed at Peterhead in Scotland, with a train of six gentlemen, among whom was the marquis of Tynemouth, son of the duke of Berwick. From Peterhead James proceeded to Newburgh, a seat of the Earl Marischal's; and passing through Aberdeen in disguise to Fetterope, he was met there by the earl of Mar, who had left Perth with a troop of horse. James now assumed the state of royalty: he formed a court, and made several peers and created knights. He was also proclaimed with great ceremony before the house where he was lodging.

In January, 1716, the Pretender made a progress through the country, entering Dundee publicly, with the earl of Mar on his right hand, and the Earl Marischal on his left. The people thronged into the market-place to kiss his hand. On the 7th of January he arrived at Scone, and on the 9th of January he made his public entry into Perth, and reviewed some of the troops. He expressed great pleasure at the sight of the Highland dress, which was new to him. In the evening he returned to Scone, where he formed a council, and issued six proclamations. On the 16th of the month, James harangued his council, having previously received addresses from the episcopal clergy of Aberdeen. His council however, being convinced, after the arrival of the Dutch troops, that the army of the Pretender could no longer resist that of Argyle, had resolved to abandon the enterprise and disperse the forces. But wishing to keep their design secret, they acted as if they meant to attack the English army. They began to raise batteries, plant guns, and even destroyed Auchterarder, Blackford, Denning, Muthell, and other places, to prevent their affording quarter and provision to the enemy. The duke of Argyle, having received supplies, marched through Auchterarder, to Tullibardine, whilst the Pretender and his followers retreated to Dundee. Suspicions now arose that the Pretender, together with the members of his council, intended to escape, and to leave the army to their fate; and the report gained ground when the Jacobite army was ordered to march to Montrose, near which several French ships lay at anchor. The rebel troops, possessed with this idea, refused to move. The earl of Mar however succeeded in pacifying them, by the assurance that James was going to place himself at their head, and by declaring that it was intended to make a stand at Aberdeen; and to add to the deception, the horses and body guard of the Pretender were drawn out before the door of the house where he lodged. James, in the meantime, slipping out by a back entrance, walked to the earl of Mar's lodgings, and proceeded to the sea-shore, where a boat conveyed him and Lord Mar on board a French ship which was then in Montrose road. The boat returned, and fetched seventeen persons of rank, who were acquainted with the Pretender's design. The Pretender reached Gravelines in a few days. The vessel returned in twelve days: and, in spite of the utmost vigilance on the part of Argyle, a very considerable portion of the noblemen and others who were engaged in this unfortunate affair escaped to France.

In France, at this time, there was little comfort for the Pretender and his friends. It was the interest of the duke of Orleans, regent during the minority of Louis XV., to maintain a good understanding with the House of Hanover. Lord Stair, the English ambassador, was urgent in his remonstrances to prevent the Pretender's return to France. On his return from Scotland, James found it necessary to dismiss Lord Bolingbroke, who had acted as his secretary, on suspicion of treachery, and the place was filled by the duke of Ormond.

The earls of Wintoun, Kenmure, and Derwentwater, of Carnwath and of Nithsdale, with lords Widdrington and Nairn, were tried at London. The prisoners of inferior rank were tried chiefly at Lancaster, where many were executed: one thousand of them, upon their petition, were transported to the Plantations in North America.

The countess of Nithsdale and Lady Nairn, waiting their opportunity behind a window-curtain, threw themselves on their knees before the king, as he passed through the apartments of St. James's palace, to beg for their husbands' lives. The king heard their appeal, but was not moved. Lady Derwentwater, with the duchesses of Richmond and Bolton, were introduced by the dukes of Richmond and St. Albans into the royal bed-chamber, where Lady Derwentwater humbly besought mercy for her husband. On the 7th of March, the earls of Derwentwater and Kenmure were beheaded on Tower Hill: lords Widdrington, Carnwath, and Nairn were reprieved. The earl of Nithsdale escaped in woman's attire brought to him by his wife. The earl of Wintoun was condemned to death, but escaped from the Tower.

There were still however proofs of disaffection. On the 29th of May the Jacobites wore oaken boughs; and on the 10th of June, the Pretender's birthday, they displayed white roses. At Oxford the spirit of disaffection was shown more plainly than in any other place. Alarmed by these and other manifestations, in 1716, King George succeeded in forming an alliance with France and the States, the chief object of which was to crush the Jacobite cause. By this treaty it was stipulated that the Pretender was to leave France, and to go beyond the Alps; nor was he to be permitted ever to set foot in France again on any pretext whatever. A renewal of that promise which had been made at the treaty of Utrecht was given; and all protection was withdrawn from James on the part of the French government. The Pretender removed into Italy.

In 1718 the Pretender became the instrument of Cardinal Alberoni's ambitious intrigues. Upon war breaking out between France and Spain, James left Urbino, where he had resided since his expulsion from France, and went to Rome. He was there advised by pope Clement XI. to go into Spain, where a squadron had been for some time fitting out against England. James was received with regal honours at Madrid; and the duke of Ormond, one of his adherents, was appointed captain-general of the expedition which was to invade England, and was authorised to proclaim the Pretender's name at certain places. But a

storm dispersed and entirely disabled the Spanish fleet off Cape Finisterre; and a descent which the Spaniards made at Kintail in Scotland (June, 1719), although aided by the Highlanders, was defeated by General Wightman. During the year 1718-19 a marriage was agreed on between the Pretender and Maria Clementina Sobieski, grand-daughter of John Sobieski, king of Poland. This princess had a million sterling for her dowry. The court of Vienna however objected to the marriage; and on her way through Tyrol to Italy the princess was seized, and placed in confinement in Innspruck. Not being released, even upon the personal application of her father, she escaped from Innspruck in man's clothes, went to Bologna, and was there married by proxy to the Pretender, who was still in Spain. Two sons, Charles-Edward and Henry, were the offspring of this union. The earl and countess of Inverness were entrusted with the charge of the eldest, styled Prince Charles. They were Protestants, a circumstance which gave great offence to their mother, and to Cardinal Alberoni, by whose counsels she was governed. After six years of married infelicity, or, as Maria Clementina terms it in her letters, 'of injuries and insults,' she withdrew, in 1725, to the convent of Cecilia, whence no intreaties of her husband could draw her, nor could he for many months obtain even an explanation of her conduct. From various letters, which are given in the 'Lockhart Papers,' it seems that, as usual, both parties considered themselves in the right. The Pretender would not part with Lord Inverness: his wife was resolved not to return to him whilst that nobleman and his wife, of whom she is said to have been jealous, remained at court. The followers of James were scandalised at this breach; at length the earl of Inverness was dismissed, and a reconciliation was effected. The earl of Inverness was a Colonel Hay, upon whom the Pretender bestowed that title in 1725, at the same time making him his secretary. He was always called Colonel Hay, except at the Pretender's court, and by the persons corresponding with it. Maria Clementina died in 1735.

In 1722 the Pretender published at Lucca his famous declaration, addressed to his loving subjects of Great Britain, and to all foreign princes and states, to serve as a foundation for a lasting peace in Europe, and signed 'James Rex.' This document, which, amongst other articles, contained a proposal to George I. to resign his crown, was pronounced by the House of Lords to be a false, insolent, and traitorous libel, and was burnt at the Royal Exchange.

The death of George I. produced no improvement in the fortunes of James Stuart, though there were continual cabals in his favour in Great Britain, and a treaty (called the treaty of Vienna) had been formed between the emperor of Germany and the king of Spain in 1725, with a view of restoring the Pretender. James, during the latter years of his life, resided entirely at Rome, where he led a quiet life, although the hope of ascending the throne of England seems never wholly to have left him. Frugal in his household, he saved, out of the pension allowed him by the pope and his share of the Sobieski estate, a sum of money sufficient to defray the expenses of a subsequent invasion of England. The events of the year 1745 belong to the history of his eldest son, rather than to the annals of the Pretender's life. He was the last of the Stuarts that received kingly honours. James Stuart died at Rome in 1765. The character of the Pretender has been variously represented. 'He began the world,' says Lockhart of Carnwath, 'with the general esteem of mankind. Every person, friend or foe, allowed him to be a wise, sober, just, good-natured prince, of great knowledge and application in business; and such as knew him, both foreigners and subjects, concurred in portending the happiness of that people over whom he should rule, and this character he maintained whilst the earl of Mar was at the head of his affairs after their return from Scotland. . . . . But soon after Mar's removal, his majesty's character and affairs appeared in a quite different light; . . . . people soon saw that they were not carried on with the dexterity and secresy as formerly; but that which struck the nail on the head was his allowing those his favourites (which seems to be a curse in a peculiar manner entailed on the royal race of Stuart) to rule under him in so absolute arbitrary a manner, that the prerogatives of a sovereign and a husband were screwed up to a pitch not tenable by the laws of God or man, nor consistent with prudence.' (*Lockhart Papers*, vol. ii., p. 405.) Mr. Leslie a non-juring clergyman, who had opportunities of conversing with the Pretender, praises his affability, good sense, freedom from bigotry, and magnanimity. By the Whig party his temper has been generally represented as morose, sullen, and disposed to tyranny.

Charles Edward Stuart, born on the 31st of December, 1721, bore the title of Prince of Wales among the Jacobites. He served in Spain under Don Carlos, who paid him great respect and attention. He is represented, a few years after this time, to have been a youth of graceful person, generous, affable, and engaging manners, 'to have the spirit of a Sobieski without the timidity of a Stuart;' and, though reared in the effeminate south, to have been capable of encountering difficulties and hardships. In the year 1743 Cardinal Tencin, the prime minister of France, who had received the purple at the recommendation of the Pretender, combined with the Jacobites in England and Ireland to project a fresh invasion of Great Britain. He persuaded the Pretender to surrender his claims to Charles Edward, and, upon his consenting, the prince set out for France, giving out that he intended to make a campaign in Piedmont, but proceeding in the disguise of a courier to Paris, where he arrived on the 20th of January, 1744. The young man was, as Tindal expresses it, 'made a loan of to France,' whose aim was to cover her own selfish designs with the plea of countenancing the Stuart family. Marshal Saxe was appointed to command the expedition; and he, having been in England, and knowing that the towns were rarely fortified, had an idea that the country could be quickly subdued.

The young prince set out for the coast of Picardy, where an army of 15,000 men was assembled, and transports were provided at Boulogne, Dunkirk, and Calais for carrying the troops to England. The army was to land on the coast of Kent, where many Jacobites were expected to rise; and at the same time a squadron sailed from Brest to convoy the transports. But the squadron fled before the British fleet under the command of Sir John Norris, and almost shared the fate of the Invincible Armada. A violent storm destroyed most of the transports, and a great part of the troops were drowned. (1744.) The prince returned to Paris, and waited a more favourable opportunity. But he was not daunted by obstacles, and the period at which the rebellion of 1745 was undertaken was favourable to its success. The king of England was in Hanover, and Scotland was almost destitute of troops. The Highlanders, disaffected, and thirsting for revenge, were ripe for revolt. Towards the end of May, 1745, Charles Edward left Paris for Nantes. William, marquis of Tullibardine, who had been attainted in 1715, Sir John Macdonald, Colonel Strictland, Mr. George Kelly, a clergyman of the Church of England, and Sir Thomas Sheridan, formerly tutor to the young Pretender, with several other gentlemen, accompanied him. On the 5th of July he sailed in La Doutelle, a French vessel, which he had joined from Nantes in a fishing-boat, designing to sail round Ireland, and to land upon the western coast of Scotland. Another ship, the Elizabeth, was ordered to accompany him as a convoy, and on board this vessel the prince had placed 400,000*l.* sterling, with arms for several thousand men. These two ships fell in with a British cruiser to the west of the Lizard Point. A fierce action ensued, and the Elizabeth was so much damaged as to be obliged to put back into Brest. The prince pursued his course to Scotland, saying that he would either die or be crowned. On the 25th of the month he landed at Boradale, a farm belonging to Macdonald of Clanronald, on the shore of the bay of Lochnanuagh. He thence proceeded to the house of Kinlochmoidart, where he was met by several Highland chieftains; and whence the clans were summoned to rise. Many persons here advised the prince to return to France, and wait another opportunity; but he was resolute in remaining. About ten days afterwards the prince set up his standard at Glenfinnin.

At this time Sir John Cope was commander-in-chief in Scotland. At first the news of the rebellion was treated with ridicule, and the government were dilatory in their measures. On the 6th of August a reward of 30,000*l.* was offered, by proclamation of the lords justices in the Gazette, to any person who should secure the eldest son of the Pretender; and on the 31st, George II. returned to London from Hanover. The prince, having heard of the price put upon his person, issued a counter proclamation, offering 30,000*l.* for apprehending the elector of Hanover. On the 27th of August he advanced in hopes of meeting Sir John Cope, but on reaching Garvamore, he found that General Cope had faced about, and taken the route by Ruthven to Inverness. No sooner did the English troops

turn their backs upon the Jacobite army, than a common soldier deserted, and carried the news to the other side. The Highlanders instantly put themselves into motion; and on arriving at Garvamore, it was determined that they should march to the south, and enter the low country, thus endeavouring to get possession of Edinburgh before General Cope should arrive there. On the 30th of August they reached Blair Athol, and the duke of Athol, who was on King George's side, retired at their approach. On the 3rd of September they entered Perth, where the Pretender's declarations were read. At Perth great numbers flocked to the Pretender's standard. Among the most considerable were the duke of Perth, Lord Strathallan, and Lord George Murray, who was the younger brother of the marquis of Tullibardine, whose right of primogeniture had been forfeited by his attachment to the exiled Stuarts; his second brother, Lord James, now duke of Athol, having succeeded to his estates and honours. Lord George Murray was a brave, humane, and honourable man; and he possessed a sound judgment in military matters. Having accepted the act of grace which passed after the rebellion of 1715, Lord George was nevertheless not possessed of that entire confidence on the part of Charles Edward which he proved himself eventually to have fully merited.

The reception which the prince met with in the Lowlands was not so cordial as he expected. On the 11th of September he marched from Perth to Dumblane; and, on the 13th, passed the Forth at the ford of the Frew, a few miles above Stirling. Colonel Gardiner's dragoons, which were posted near Stirling, withdrew at his approach. On the 15th instant the rebels arrived within nine miles of Edinburgh, and Gardiner's and Hamilton's dragoons were posted within two miles of it. The city had been hastily fortified; a thousand men had been armed for its defence, in addition to the city guard; and trained bands of mixed Whigs and Jacobites were constantly on duty. Everything was so prepared that the town might have held out for some days before troops which had not a single cannon. 'But,' says an anonymous writer, 'to the lasting dishonour of Scotland, the capital was given up to a handful of half-starved savages, without stroke of sword.'

On the 15th of September, being Sunday, public worship was suspended, and the volunteers were under arms all day. On Monday, until noon, the defence was carried on very vigorously; but about two o'clock a petition was set on foot, praying the magistrates and town-council to call a meeting of the chief inhabitants, to deliberate concerning the propriety of delivering the town up to Charles Edward. About this time, the dragoons first, and afterwards the officers of the crown, left the city, the dragoons taking the route of Musselburgh and Haddington. The result of the public meeting, which was principally composed of Jacobites, was a determination to surrender the town, and place the arms of the volunteers in the castle. A deputation was dispatched to Gray's Hill, about two miles from Edinburgh, where Charles Edward then was. Whilst the terms of capitulation were still under discussion, intelligence came that General Cope had arrived at Dunbar, and would speedily march to the relief of the town. A second deputation was sent, to gain time; and those who composed it returned to the city early in the morning of Tuesday the 17th in a coach. The coach entered at the West Port, and drove down the street towards the Canongate. On the gate being opened, a body of 900 Highlanders, under the command of Lochiel and Sullivan, rushed in: the lord provost and town council, who were waiting the return of the deputation in the street, on hearing of this event, retired to their homes. At noon, Charles, in a Highland dress, attended by the duke of Perth and Lord Elcho, came by Duddingston into the King's Park, and entered through St. Anne's Yard into Holyrood Palace. There was a great crowd assembled to receive him, and the young prince was one whose personal appearance might seem to justify the enthusiasm which he inspired. 'The figure and presence of Charles,' observes Mr. Home, who witnessed his entrance to Holyrood, 'were not ill suited to his lofty pretensions. He was in the prime of youth, tall and handsome, and of a fair complexion.' As he entered the palace there was an expression of languor and melancholy in his countenance: the Jacobites compared him to Robert Bruce; the Whigs declared that he looked like a gentleman and a man of fashion, but not like a conqueror. After dismounting, the prince walked towards the apartments of the duke of Hamilton: when he was near the door, a gentleman moved out of the crowd, drew his sword, and walked up stairs before the prince. This was James Hepburn of Keith, who had been engaged when very young in the rebellion of 1715; a gentleman who is said to have been a model of manliness, simplicity, and honour; but whose hatred of the Union, rather than love of the Stuart race, induced him to sacrifice himself to a notion of national independence.

In the meantime Sir John Cope had marched from Dunbar to Haddington, and thence to Prestonpans and Seaton. A council of war had been held by Charles Edward at Duddingston, where he had proposed to engage General Cope's army. This was agreed on; but when the prince declared his resolution to lead the troops to battle himself, the chiefs remonstrated, and with some difficulty induced him to give up the design. On the next morning (Sept. 21) the Highlanders advanced to Tranent; and to the west of the town continued their march until they saw the king's soldiers encamped near Preston. A loud shout was raised by the English, and returned by the Highland troops. A morass, which was pronounced to be impassable, divided the armies. The afternoon was spent in movements. At night both armies lay down to repose, the Highlanders with the resolution of attacking the king's troops early in the morning. During the night, a country gentleman, who knew the ground well, proposed to Lord George Murray to show him a part of the morass whence the rebels might attack their enemies without observation. Lord George referred him to Prince Charles, who was sleeping on the ground with a sheaf of pease-straw under his head. Charles was pleased with the proposal, and before break of day his troops began to move. They marched through a sort of valley, or hollow, concealed by the darkness first, and afterwards by a mist. Charles took his place between the first and second line. At length the morass being passed, the two armies were separated only by a corn-field. The Highlanders, ill armed and without cannon, followed up the advantage which they had gained with wonderful success. A panic seized the king's troops. The Highlanders threw down their musquets, drew their swords, and pursued the enemy. 'In a very few minutes,' says Home, 'after the first cannon was fired, the whole army, both horse and foot, were put to flight. Not one of the soldiers attempted to reload their musquets, and not one bayonet was stained with blood.' All the king's infantry was killed, or taken prisoners, except about 170, who escaped by great speed, or other good fortune. This was called the battle of Prestonpans.

The second line of the Highland troops, commanded by Prince Charles, had kept so near the first as to appear to General Cope all one body. The Prince was only fifty paces behind the vanguard—a proof of courage which his enemies could not deny; but it was a departure from his agreement with the chiefs, who had made conditions that he should not expose himself to imminent danger.

General Cope's conduct was severely censured; but when inquired into by a board of general officers, he was not censured, and the conduct of the soldiery was made to bear the blame. 'His great error,' observes Sir Walter Scott, 'was in drawing up his forces in front of a high park wall, which barred their escape from their light-heeled enemies.' Collecting his dragoons, Cope, with the earls of Loudon and Home, marched to Berwick, where Lord Mark Ker received him with this sarcasm, 'that he believed he was the first general in Europe that had brought the first tidings of his own defeat.'

Great apprehension was now entertained in England lest the prince should immediately march southwards. But Charles and his council did not deem it prudent to appear in England with so small an army, and they resolved to wait some time longer at Edinburgh. The castle of Edinburgh remained still in the possession of the king's troops, commanded by General Guest. At first the garrison was supplied with necessaries from the town, but on the 29th of September orders were given to allow no person to pass into the castle. A letter was that evening sent down by General Guest to the provost of Edinburgh, declaring that unless a free communication was opened with the garrison and the town, the general would commence a cannonade upon the city. The prince, on hearing of this threat, ordered the communication to be re-opened. But the Highlanders having, on the 1st of October, fired at some people who were carrying provisions to the castle, the garrison on the next day began to fire on the houses that covered the prince's Highland guard. Upon this a contest

commenced between Prince Charles and General Guest, during which several houses were set on fire, and several persons on both sides killed. The cannonade lasted till the evening of the 5th of October, when Prince Charles at last published a proclamation permitting a communication between the town and the castle. Very few of the inhabitants of Edinburgh joined the Pretender during these destructive reprisals. There was, in fact, a disinclination among the common people to flock to his standard. Lord Kilmarnock and Arthur Elphinstone, afterwards Lord Balmerino, at this time joined the prince, and Lord Ogilvie, eldest son of Lord Airly, arrived in Edinburgh with a regiment of 600 men. These additions, and reinforcements sent by a few other noblemen and gentlemen, chiefly in the neighbourhood of the Highlands, together with supplies of arms and ammunition from France, strengthened the prince's cause.

It was now discussed by the prince's council in what manner their advantage could best be prosecuted. The prince, who was totally unacquainted with the country which he had invaded, could not bear opposition, nor listen to advice. Feuds and intrigues divided his little court; and too great confidence in his own opinion made him positive and resolute, when he ought to have been cautious. Having received all the reinforcements that he expected, he one day suddenly apprised his council that he was resolved to march to Newcastle, and to oppose the progress of Marshal Wade, who had advanced to that town. It was in vain that several of his friends opposed his determination. Three times it was brought before the council, and on the last discussion the prince settled the point by these words: 'I see, gentlemen, that you are determined to stay in Scotland, and defend your country; but I am also resolved to try my fate in England, even if I should go alone.'

On the 31st of October, Charles marched out of Edinburgh, leaving Lord Strathallan to command in Scotland. At Dalkeith House he was joined by the clan Macpherson and some other Highlanders, amounting in all to about 1000 men: this made his whole force about 6500. With one division of his army the prince marched to Kelso, then taking the Jedburgh road, he crossed the Esk, and on the 8th of November reached Brampton in Cumberland. On the next day the other division of the army arrived, and proceeded to invest Carlisle, which surrendered to the duke of Perth on the 15th of November. It was now determined to march directly to London. Before Charles had set foot on English ground, three armies, each of them superior in number to his own, were prepared to oppose his progress: one, under General Wade, at Newcastle; a second, in Lancashire, commanded first by General Ligonier, and afterwards by the duke of Cumberland; and a third, consisting of old regiments, was stationed in the villages near London, and was, in case of need, to have been commanded either by the king or the earl of Stair. The rebel troops nevertheless leaving a garrison in Carlisle, marched forward in two divisions; the first, commanded by Lord George Murray, arrived at Penrith on the 21st of November; the second, or main body, headed by Charles, chiefly composed of Highland regiments, and having the cannon, followed, and advanced from Penrith, by Shap, Kendal, Lancaster, and Garstang, to Preston. On the 29th they reached Manchester, by way of Wigan, and were joined by 200 or 300 of the common people. These men, the only Englishmen who joined the standard of the Pretender, were called the Manchester regiment, and were commanded by Colonel Townley, a Roman Catholic. Preston and Manchester were the only places where ringing of bells or acclamations were heard. From Manchester the rebel army marched to Macclesfield: from Macclesfield, the two divisions went by different roads; the one by Congleton, the other to Leek, and from Leek by Ashbourn to Derby, where on the 4th of December (1745) both divisions arrived. During the march from Carlisle to Derby, the prince learned that John Drummond, the duke of Perth's brother, had arrived at Montrose with his own regiment, the royal Scots, Fitzjames's regiment of horse, and the picquets of six Irish regiments in the service of France.

The duke of Cumberland's forces lay at Litchfield, Coventry, and Stafford. It seemed at first to be the intention of the rebels to avoid the duke, and to advance to London; but after halting a day or two in Derby, they altered their intention, chiefly upon the representation of George Murray, and retreated, with the design of meeting Lord Drummond's army, which was coming from the north. The retreat was resolved upon by the advice of Lord George Murray, and much to the dissatisfaction of Prince Charles. The duke of Cumberland now began the pursuit of the rebels, who were only two days' march before him. Lord George Murray, who commanded the rear-guard, defeated the duke's dragoons at Clifton near Penrith in a skirmish, in which the Highlanders fought with their usual courage, and Lord George, bareheaded (having lost his bonnet and wig), was foremost in the encounter. On the 20th of December the Scottish army left Carlisle, and crossed the Esk into Scotland. On this occasion the prince saved one of his men from being drowned by catching him by the hair. The Highland troops marched unmolested by Moffat and Dumfries to Glasgow, where they were by no means welcome. At Glasgow they remained seven or eight days, and the troops then began their march to Stirling, in two divisions. When the troops came near Stirling, the prince took up his abode in a house called Bannockburn. Lord George Murray's division occupied Falkirk. The town of Stirling soon surrendered, and Charles's army, now, by the junction of the forces of Lord Strathallan and Drummond, amounting to 9000 men, attacked the castle of Stirling. On the 16th of the month General Hawley left Edinburgh, which he had entered during Charles's absence, and marched to Falkirk; so that his army was now only seven miles distant from that of the Pretender. Lord George Murray marched at the head of the Macdonalds of Keppoch with his drawn sword in his hand. The Macdonalds began the fight, and repulsed the king's dragoons. 'When the Macdonalds came near the foot of the king's army,' says Home, 'some regiments of the first line gave them a fire; the rebels returned the fire, and throwing down their muskets, drew their swords, and attacked the regiments in the left of the king's army both in front and flank; all the regiments in the first line of the king's army gave way; as did most regiments of the second line. It seemed a total rout; and for some time General Hawley did not know that any one regiment of his army was standing.' General Hawley retreated to Linlithgow, leaving seven pieces of cannon and a quantity of provision, ammunition, &c. upon the field. A strong body of Highlanders, commanded by Lord George Murray, immediately took possession of Falkirk.

The friends of the House of Hanover were greatly dejected on hearing of the defeat; whilst the generals of the rebel party deemed it incomplete, and blamed each other. Charles remained at his quarters that night, and on the following day returned to Bannockburn. Meantime the siege of Stirling Castle proceeded slowly, owing to the superior fire of the castle. On the 30th of January the duke of Cumberland arrived at Edinburgh, whither General Hawley had retired; and on the following day the duke marched against the enemy. Lord George Murray with the clan regiments was now at Falkirk, and Prince Charles was still in the house of Bannockburn. The rebels at first resolved to make a stand, and to give the duke battle; but on the following morning they suddenly raised the siege of Stirling Castle, and retreated. Two explosions were the first signal of this event which reached the duke's ears; these were the powder-magazines blown up by the Highland troops, who retreated in disorder over the river Forth.

The Highlanders marched through Dumblane to Crieff, where the two divisions of their army separated: one, under Prince Charles, marched north by the highland road; the other, commanded by Lord George, proceeded through Montrose and Aberdeen, by the coast road, to Inverness. In the vicinity of that town both divisions approached each other. Charles, suffering his men to straggle about, lodged at Moy, the seat of Mackintosh, about ten miles from Inverness. Here he was saved from a surprise by the presence of mind of a woman. Lord Loudon, who was at Inverness, hearing that the prince had only five or six hundred men with him, set out one evening as soon as it was dark, with a design to seize him. Lady Mackintosh, the wife of Charles's host, is supposed to have been apprised of this attempt by letters from her mother. Without saying a word to Charles, she ordered five or six of the people, well armed, to watch on the road from Inverness, under the direction of a country smith. When Lord Loudon's troops drew near, the smith and his party gave them a shot or two, calling upon the Macdonalds and Camerons to join them. Lord Loudon's men, deceived by these shouts, retreated precipitately to Inverness, and many of

them were trampled down in the confusion of their flight. Charles, on the following day, hearing of this skirmish, which was called the Rout of Moy, marched to Inverness. Upon Lord London retreating, he laid siege first to Fort George, and next to Fort Augustus, both of which places he captured. During the months of February and March a desultory war was carried on, until, at the end of March, news was brought that the duke of Cumberland was marching towards Inverness with all his forces. On the 14th of April, Charles retreated from Inverness to Nairn, where he again made a stand. That night the Highlanders slept amid the furze and trees of Culloden wood, about three miles from Nairn. The prince's army was now much dispersed, and many of his best officers were absent. The Master of Lovat, son of Lord Lovat, was, as well as others, recruiting his forces. Lochiel however joined the army of Charles with his regiment; and, on the 15th, the army, reinforced by Keppoch and his regiment, was drawn out in order of battle upon Drummossie Muir, about a mile and a half to the southeast of Culloden House. About two o'clock the men were ordered to their quarters, and Charles, calling together the generals, announced his intention of making an attack upon the duke's army, then at Nairn. When he explained his design, the duke of Perth and John Drummond dissented; and Lochiel remarked, that on the next day the prince's army would be stronger by fifteen hundred men. But the matter was decided, when Lord George Murray seconded Charles's proposal, and urged the advantage of a night attack. Many men had gone to Inverness to get food; and the ranks were thinned: but Charles, bent upon a night attack, ordered the men to march at eight o'clock. At the appointed hour the Highland army advanced in a column, with an interval in the middle, according to a plan of Lord George Murray's, who marched in the front at the head of the Athol brigade. Charles and the duke of Perth were in the centre of the line of march. The night was very dark, and was far spent before the Highlanders reached Kilravock wood, where the officers, finding by their repeating-watches that it was two o'clock in the morning, consulted what was to be done; as Nairn was still more than three miles off, and it would be daylight before they could reach it. The matter was decided by Mr. Hepburn, who, on hearing a drum in the enemy's camp, observed, that if they should retreat they would be pursued; and that they would then be in a worse condition than they now were. The duke of Cumberland had gained intelligence of the attempt, and by five o'clock in the morning his army was on its march. The Highlanders, weary and dispirited, retraced their steps to Culloden, where many of them lay down to sleep. About eight o'clock the duke's forces were seen marching towards them; and about twelve, they were within two miles and a half of the rebels. About one o'clock a heavy cannonade was begun by the king's troops, and continued till two. The Highland regiments suffered severely, and a very inefficient fire was returned from their cannon. Colonel Belford, of the artillery, seeing a body of horse with Charles, who was stationed on a small eminence behind the right of the second line, pointed two pieces of cannon at them; one of Charles's servants, who stood behind him with a led horse, was killed, and the face of the prince was bespattered with dust. The Highlanders now became impatient to attack. A messenger was sent to Lochiel, representing the necessity for doing something. Whilst Lochiel was speaking to Lord George Murray, the Mackintosh regiment broke out from the line, and drove back the king's troops, sword in hand, but they were mostly brought to the ground by a terrible fire. A few desperate men pressed on, and perished by the bayonet. The Macdonalds and other Highland regiments now retired: it is said that the former were affronted by being deprived of the right, the post of honour, which their clan had possessed from time immemorial. It was in vain that the duke of Perth called upon them to behave themselves, and make a right of the left, declaring that if they did, 'he would henceforth call his name Macdonald.' The Highlanders were dispirited, and their condition became desperate.

At this crisis the duke of Cumberland advanced with the infantry, and the Highlanders fled; some retired to Badenoch, and others to the hills. Many who had fasted all day ran twenty miles without tasting food. The Fraser and Drummond's regiment retired to Inverness. The dragoons pursued and slaughtered the fugitives. When Charles saw, for the first time, his Highlanders repulsed and flying, he advanced to rally them; but Sir Thomas Sheridan dissuaded him from the fruitless attempt. The entreaty would not have availed, according to the testimony of the prince's standard-bearer, if General Sullivan had not led the prince's horse by the bridle from the field. Whilst some Highland troops still kept their ground, Lord Elcho, it is said, rode up to the prince, and exhorted him to make one final attempt to rally, or, at least, to die like one worthy of a crown. The reply was hesitating. Lord Elcho, with execrations, turned from him, for whom he had sacrificed everything, and swore never to see his face again; an oath which he kept.

The rebels are said to have lost about 1000 men; and among these were the bravest and the most devoted to the cause. The prince, after dismissing the troops which followed him, went to Gorthleck, where Lord Lovat was, and whence he sent a farewell message to the remnant of his army, thanking them for their services, but desiring them to attend to their own preservation. He next proceeded to Invergarie, near Fort Augustus, where he took leave of all his followers except Sullivan, O'Neil, and Burke, a servant who knew the country. Charles had now resolved to escape to France. For a time he kept about the islands of North and South Uist, sometimes in fishermen's huts, sometimes subsisting upon the bounty of the islanders; but generally in a state of the utmost privation. Hunted from place to place by the king's troops, his adventures are scarcely equalled by the fictions of any romance. General Campbell searched the island of Barra and South Uist in vain; and Long Island, in which he also took shelter, was surrounded by frigates and sloops of war. In this perilous condition Charles remained until the end of June, when he was delivered from his danger. Flora Macdonald, the daughter of Macdonald of Melton, in the isle of South Uist, was the generous and courageous woman who risked her life to save that of the prince. She had heard of his misfortunes and dangers, and expressed a wish to assist him. Charles was introduced to Flora, who undertook to convey him to Skye as her maid, dressed in female attire. As no one was allowed to go without a passport, she procured one for herself and her supposed maid Betty Burke. On the evening before they were to sail, she and Lady Clanronald met the prince at a place near Ormaclade, on the sea-shore. Whilst they were at supper here, news came that a party of officers and soldiers were searching Ormaclade in quest of Charles. Shortly afterwards, on seeing four armed cutters at a little distance, the ladies and the prince hid themselves among the rocks. About eight in the evening they sailed; and although threatened by a party of the Macleod's militia, who saw them from the shore, they pursued their way to Kilbride in Skye. Here Flora intended to lodge the prince at Mugstot, the seat of Sir Alexander Macdonald, but several of the king's soldiers being in the house, he was sheltered at the house of Macdonald of Kingsburgh, Sir Alexander's factor. On the following day Charles changed his attire, and crossed over to Rasay, where he lodged for some time in a cow-house; but growing impatient in this retreat, he returned to Skye, where he was assisted by the Mackinnons, and by their aid sailed to Loch Nevis, a lake in the mainland, where he was put ashore on the 5th of July. Here a number of the king's troops were stationed, and Charles was now enclosed between a line of posts formed by the officers who had notice of his situation. To escape this danger, he was forced, with a friend, to creep up the channel of a brook which was between two of these posts. He was accompanied by Macdonald of Glenaladale, with whom, after surmounting numerous difficulties, he reached the hill of Corado, between Kintail and Glenmoriston. Here he found some of his faithful followers living in a cave: wretched and altered as he was, his brave adherents knew him, and fell upon their knees. 'He had,' says Home, 'a coat of coarse dark-coloured cloth, and a wretched yellow wig, with a bonnet on his head. His brogues were tied with thongs, so worn that they would hardly keep on his feet. His shirt was saffron, and he had not another.' He remained in this cave five weeks and three days; and not even the reward of 30,000*l.* which was offered for his person, would have tempted these poor men, who sheltered the wretched descendant of the Stuarts. He continued his wanderings for many weeks; sometimes becoming so exhausted from fatigue and want of food, that he could not walk without help: at length, after many narrow escapes, he was able to cross Locharkaig,

and reach the fir-wood near Achnacarry. Here he heard from his faithful chieftains, Lochiel and Cluny, that they were at Badenoch, where he might with some risk join them. About the 29th of August Charles met his two friends, and was conducted by them to Letternilick, a remote place in the great mountain Benalder, where he remained until a vessel arrived at Lochnanuagh to convey him to France. On the 19th of September he reached Boradale, travelling only by night, and sailed for France on the 20th. he arrived at Morlaix in Brittany, on the 29th of September, 1746. During the wanderings of the prince, the secret of his concealment had been entrusted to hundreds of persons of every age and sex. Flora Macdonald was for some time confined in the Tower, but, being liberated, she found a home for a short time in the house of Lady Primrose, a Jacobite lady. No organised scheme for establishing Charles Edward upon the throne of England was ever afterwards formed.

Charles was received in France with professions of affection from Louis XV.; and, until his departure from France became necessary to ensure peace with England, he was well treated by the French king. In 1748, after the peace of Aix-la-Chapelle, the king of France could not allow him any longer to remain in his dominions. Charles long resisted the attempts made to induce him to leave France; and notwithstanding a letter from his father, recommending him to comply with the wishes of Louis, he remained at Paris. At length Charles, in stepping out of a coach from the Opera, was seized, and sent to Vincennes: and he was afterwards conducted with a guard out of the kingdom. After some delay he repaired to Rome. Charles Edward married a princess of the house of Stolberg in Germany, who survived him, and married Alfieri. [Alfieri.] The union was not happy, and the latter period of the prince's life was disgraced by habits of intoxication. He had no issue by his wife; but he left a natural daughter, whom he created duchess of Albany, and to whom he bequeathed a considerable property. For many years Charles seems to have cherished hopes of recovering the crown of Great Britain; but at length, when his claims ceased to be sustained by any foreign power, and when the courts of Europe no longer gave him the title of Prince of Wales, he took the title of Count of Albany, and sank into a habit of life strangely contrasted with his former activity. He died on the 31st of January, 1788. Notwithstanding his failings, Charles Edward possessed much energy and talent. His brother, Henry Benedict, who was created by the old Pretender duke of York, and afterwards made Cardinal York, was the last representative of the royal house of Stuart. Henry Benedict died at Rome in 1807.

STUART, ARABELLA, or ARBELLA, often styled, both by her contemporaries and by subsequent writers, the Lady Arabella, was the only child of Charles Stuart, duke of Lennox, younger brother of Henry, lord Darnley, the father of James I. James and she therefore were full cousins. Her mother was Elizabeth, daughter of Sir William Cavendish, father of the first earl of Devonshire. The birth of the Lady Arabella has been variously placed; in 1575 (by Oldys, in MSS. referred to by Kippis, 2nd edit. of *Biog. Brit.*), in 1575 or 1576 (Ellis's *Letters*, 2nd series, iii. 64), in 1577 (article 'Arabella,' in *Biog. Brit.*, written by Morant, who however states in a note in the same page that her father died in 1576, and 'left behind him' this his only child). Other accounts of the Lennox family assert that Arabella's mother died, before her husband, in 1574. (Fisher's *Companion and Key to the History of England*, p. 188.) The Lady Arabella also stood in the same degree of relationship to Elizabeth that James himself did through his mother; both were great grandchildren of Henry VIII.'s eldest sister Margaret; James through his mother, Queen Mary, and her father James V. of Scotland, son of that princess by her first husband; Arabella, by her father, Charles Stuart, and his mother, Margaret Douglas, the daughter of the English princess by her second husband, Archibald Douglas, earl of Angus. She was born in England; and during the reign of Elizabeth that circumstance was openly stated by Parsons, the Jesuit (in his *Conference about the next Succession to the Crown*, published under the name of Dolman, in 1594), as giving her claim to the throne an advantage over that of the Scottish king. At all events she was undoubtedly, before the birth of his son Henry, in February, 1594, the next in order of succession to James; and if he had died without issue, she would have been Elizabeth's heir, upon the same principle that he was so accounted.

The position in which she was thus placed by her illustrious descent, and near connection with the thrones both of England and Scotland, forms the key to the history of the Lady Arabella. While she was yet very young, it is said that her cousin, King James, wished to have her married to her relation, Lord Esme Stuart, whom he looked upon as his heir in case he should die childless, and whom he had created duke of Lennox; but this scheme, which must have been projected before 1583, the year in which Esme, duke of Lennox, died, was defeated by the opposition of Elizabeth. When she grew up, other matrimonial speculations were entertained with regard to her, some by herself, some by others; for a full account of which the reader is referred to the *Biog. Brit.*, and to Mr. D'Israeli's paper on 'The Loves of the Lady Arabella,' in his *Curiosities of Literature* (pp. 357-363, edit. of 1838). She first became an object of general public attention by the manner in which her name was brought forward in 1603, immediately after the accession of James, in the affair of the alleged plot called 'the Main,' for which Sir Walter Raleigh was tried: one of the charges against Raleigh was, that he designed to raise the Lady Arabella to the throne, under the protection of Spain. There is no probability however that any such design ever was entertained; it is at any rate admitted on all hands that the Lady Arabella knew nothing of it. (Howell's *State Trials*, ii. 1-60; Jardine's *Criminal Trials*, i. 389-520; Lingard's *Hist. of Eng.*, ix. 8-18; Tytler's *Life of Raleigh*, pp. 257-301.) But her situation was sufficiently difficult and dangerous one, without this unfounded suspicion or imputation; the more especially as she appears to have been entirely dependent even for subsistence upon the bounty of the crown. James's wish probably was, that she should remain unmarried; but in February, 1609, a discovery was made of a love affair in which she was engaged with a companion of her childhood, Mr. William Seymour, second son of Lord Beauchamp, the eldest son of the Earl of Hertford; and, although both parties were called before the council, and there sharply reprimanded and warned to take heed of what they were about, their affection disregarding all consequences, they managed to get secretly married very soon after. The marriage was discovered in the summer of the following year, 1610; on which Seymour was immediately committed to the Tower, and the lady placed under custody in the house of Sir Thomas Parry at Lambeth, from which it was some months after ordered that she should be transferred to Durham, there to remain under the charge of the bishop. This marriage probably excited James's alarm and fury the more, inasmuch as the Seymours inherited a claim to the crown which many persons thought better than his own, in virtue of their descent from Mary, the youngest sister of Henry VIII., upon whose representatives that king had settled the succession, in case of failure of his own issue, by a will which an act of parliament had certainly authorised him to make. [Henry VIII.] The Lady Arabella had scarcely set out on her forced journey to the north, in April, 1611, when she was taken ill, or professed to be taken ill, at Highgate; and here, in consequence, at the house of a Mr. Conyers, she obtained leave to remain, first for one and then for another month. When that term was about to expire, she set out, disguised in male apparel, and, attended by a Mr. Markham, about three o'clock in the afternoon of Monday the 3rd of June, took horse at a little inn about a mile and a half distant, and about six o'clock reached Blackwall, where, going into a boat that was in readiness, she was rowed down the river, and next morning was taken on board a French vessel that waited for her and her husband at Lee. Seymour meanwhile had also contrived to effect his escape from the Tower; but as he did not make his appearance so soon as had been agreed upon, the vessel set sail without him, and he was obliged to make a bargain with a coaster from Newcastle to take him across to Flanders, which he reached in safety. His wife was not so fortunate; a small ship of war was immediately despatched from the Downs to intercept her, and she was captured in Calais Roads. She and Seymour never again met. She was thrown into the Tower, where sickness and sorrow after some time deprived the poor victim of her senses, and she died insane in her prison, on the 27th of September, 1615. Many of her letters that have been preserved, and which have been printed by Mr. D'Israeli, Ballard (*Memoirs of*

British Ladies), and others, show that the Lady Arabella united no ordinary talent and literary accomplishment to her high spirit and passionate strength of character; and she also appears to have possessed a considerable share of personal beauty. Seymour was not only permitted to return to England the year after the death of his wife, but was the same year created a baronet; and, his father having died previously, he became earl of Hertfort on the decease of his grandfather, in 1621, and in 1640 was made marquess of Hertford, under which title he makes a considerable figure in the history of the civil war, in which he fought on the side of the crown, although he had allied himself to the parliamentary general the Earl of Essex by marrying his sister. He just lived to witness the Restoration, and to be restored by Charles II. to the dukedom of Somerset, which had been forfeited, as it had been acquired, by his great-grandfather the Protector; he died 24th October, 1660. It is worthy of being noted, that to one of his daughters by his second wife, he gave the name of her whom he had first loved and had not forgotten.

STUART, JAMES, frequently distinguished by the name of *Athenian* Stuart, was born in Creed-lane, Ludgate-street, in 1713, of parents in a very humble rank of life, and by the death of his father he was left, at a very early age, the eldest of a family reduced by that event almost to indigence. Beyond this no particulars are known relative to the intervening period before he could at all have contributed to the support of the family by his pencil. In the absence of evidence to the contrary, it may safely be assumed that his education must have been a very slender one; and that, in all probability, he had received very little instruction, if any, in drawing, when the talent he showed for it recommended him to Goupy, who kept a shop in the Strand, and who employed him to design and paint ladies' fans—a branch of art at that time greatly in vogue, and more encouraged than any higher kind of painting. Such was the school in which the future investigator of Athens and its monuments was trained. Fortunately Goupy himself was an artist of some ability, both as an engraver and painter in body colours, and being acquainted with the works of the best masters, his instructions were no doubt advantageous to Stuart. He continued with Goupy till about 1742, when he set out for Italy, for the purpose of improving himself. Little more is known of him during his residence in Italy, than that after staying at Rome nearly seven years, industriously occupied in painting, he embraced the offer made to him by his friend Revett, and Gavin Hamilton, of joining them in an excursion to Greece; though Hamilton, who was probably the originator of the scheme, afterwards declined accompanying them.

Revett (Nicholas, second son of John Revett, of Brandeston Hall, Suffolk) may be supposed to have been better qualified by education for an undertaking which required some knowledge of antiquity, whereas Stuart may be thought to have been very ill prepared. He had however, during his long residence at Rome, applied himself so diligently to the study both of the classical tongues and of archæology, at the College della Propaganda, as to be able to give proof of his proficiency in a Latin dissertation, 'De Obelisco Cæsaris Augusti Campo Martis nuperrimè effosso,' dedicated to Viscount Malton, and printed in 1750, at the pope's expense. Whether either himself or his companion had paid particular attention to architecture is doubtful, or rather, the probability is that they were acquainted with it merely as a collateral branch of art. At all events, it is not a little remarkable that it should have been reserved for two *painters* to show the world what Grecian architecture was, and thereby lead to a complete revolution in architectural taste. Having previously issued a prospectus of their undertaking, and raised funds for their tour, by subscriptions received from England, the travellers quitted Rome in March, 1750; and after passing some time at Venice, made an excursion to Pola in the following July, where they employed themselves three months in making drawings of the amphitheatre, &c., which however formed no part of their original work, and remained unpublished till 1816, when they first appeared in a fourth or supplementary volume, edited by Mr. Joseph Woods. In March, 1751, they reached Athens, where they remained till about the end of 1753; and while there, Stuart met with Mr. Dawkins, a lover of antient art, the companion and patron of Wood (author of 'Ruins of Palmyra'), and who afterwards proved a most liberal patron to Stuart also on his return to England, affording him both encouragement and assistance in preparing his materials for publication. Dawkins himself however did not live to see the 'Antiquities of Athens' in a published form, for he died about two years before the work was brought out.

Stuart and his companion returned to England in the beginning of 1755, but it was not until several years afterwards (1762) that the first volume of the 'Antiquities' was published. Stuart appears to have had by far the greater share in the labour, and the literary part is ascribed entirely to him. The work was well received by the learned, and by artists, notwithstanding that, owing to the delay in bringing it out, the subject had been forestalled by Leroi's 'Ruines,' &c. [LEROI.] The greater care bestowed upon the English work gave it however a permanent architectural value, while the rival one has fallen into disrepute as untrustworthy, and, though by a professional architect, as being more pictorial than antiquarian. Perhaps it was rather an advantage to Stuart, that in examining Grecian architecture he was unbiassed by any previous professional prejudices, and had nothing to unlearn. Still it was not every one who was satisfied with the first portion of the 'Antiquities;' for Winckelmann has spoken of it very disparagingly in a letter to Fuessly, where he hints that it had disappointed many persons both in England and elsewhere. Its success however admits of no dispute. There was considerable encouragement afforded just then to such studies, and it was about the same time that Adam published his work on Diocletian's Palace [ADAM], while Wood's 'Ruins of Palmyra' and 'Ruins of Baalbec' had appeared a few years previously, and the 'Ionian Antiquities' somewhat later.

The patronage and encouragement which Stuart received did not cause him to prosecute the continuation of his work very diligently, for the second volume was not entirely completed, and the third only in progress, at the time of his death. Neither was he very eager to avail himself to the extent he might have done of the opportunities afforded him as a practising architect. His patrons, the Marquis of Rockingham, Lord Anson, &c., had aided him so effectually, the latter bestowing on him the appointment of surveyor of Greenwich Hospital, that he was now in easy circumstances, and willingly relaxed from that continued exertion which prudence no longer imposed upon him as a duty. His employment as an architect was consequently by no means so extensive as it might have been, or equal to what his celebrity would have obtained for him. His principal work is the chapel of Greenwich Hospital, as rebuilt by him, after being destroyed by fire; but although beautiful as regards the details, and the individual decorations borrowed from Grecian architecture, it is not, if considered as a whole, very Grecian in character, if only because the numerous arched windows stamp it with a very different one. For Lord Anson he built a mansion in St. James's Square, and also several ornamental structures, in imitation of antique models, in the grounds of that nobleman's seat at Shuckburgh. He also erected Mrs. Montagu's house, Portman-square, and some other private mansions, but none of any particular note for their architecture.

Stuart was twice married. When he had reached the mature age of sixty-seven, he took for his second wife a very young woman, by whom he had five children; among them a son, who entered the navy, and died in 1800. Another boy, who is said to have exhibited an extraordinary talent for drawing, was carried off by the small-pox, not very long before his father's death, which occurred on the 2nd of February, 1788. The second volume of the 'Antiquities' was edited by Newton, in 1790; and the third, by Reveley, in 1794.

Between Stuart and his colleague Revett some differences appear to have taken place relative to the management of their joint publication, which were arranged by Stuart purchasing Revett's share in it, and such materials as he had provided towards the completion. Having got rid of that engagement, Revett undertook a second antiquarian expedition at the expense of the Dilettanti Society, for the purpose of exploring the remains of antient architecture in Ionia. The result of this tour, which occupied him about two years in company with Dr. Chandler, was the 'Ionian Antiquities,' the first volume of which was published in 1769. Like Stuart, he afterwards practised as an architect, was employed by Lord le Despencer at West Wycombe, and erected the church at Ayot, St. Lawrence, Herts, but was so far from realising an independence, that

le died in very straitened circumstances, in 1804, at the age of eighty-two.

STUART, GILBERT, LL.D., was the son of Mr. George Stuart, who was related to the learned grammarian Ruddiman, and filled the office of professor of Humanity, or Latin, in the University of Edinburgh, with much reputation, till his death in 1793. Gilbert was born at Edinburgh, according to the common account, in 1746; but in 1742, according to Kerr's *Memoirs of Smellie* (i., 499, and ii., 2). He was educated for the profession of the law; but a passion for general literature early took possession of him, and drew him off from his legal studies, so that he never was called to the bar. He first made himself known by his 'Historical Disquisition concerning the Antiquity of the British Constitution,' which he published in 1767, and which was held to have so much merit, that the University of Edinburgh immediately bestowed upon the youthful author the degree of LL.D. In the following year appeared his 'View of Society in Europe, in its Progress from Rudeness to Refinement; or, Inquiries concerning the History of Laws, Government, and Manners.' This work, which reached a second edition in 1778, displayed great reading, as well as ingenuity of speculation. Soon after it first appeared, the professorship of public law in the University of Edinburgh became vacant, and Stuart applied to the crown for the appointment, but unsuccessfully, in consequence, as he conceived, of the interference of the Principal, Dr. Robertson. This notion, and the event out of which it arose, had a great influence on the future course of Stuart's life and literary labours. If Robertson really did use his influence to prevent his appointment to the academical chair, it is believed that his reason was, the character for dissipation and intemperance which Stuart had already established for himself, notwithstanding his occasional hard reading and violent paroxysms of study. From this time he evinced, in addition to his unfortunate habits of life, a temper the most envious, malignant, and revengeful, which went far to destroy all the value of his undoubted learning and talents. On his failure in the matter of the professorship, he left Edinburgh for London, but without leaving behind him his personal resentments, which seem to have comprehended the general body of the literary men of his native city. In London, where he resided from 1768 to 1773, he is understood to have been chiefly employed in writing for the 'Monthly Review.' But he also found time to produce, in 1772, a satirical attack upon the newly published Latin Grammar of Dr. Adam, the rector of the High School of Edinburgh, under the title of 'Animadversions on Mr. Adam's Grammar, by Jo. Rich. Bushby;' and he is also understood to have been the writer of other papers in ridicule both of Adam's book and of himself, which appeared about the same time in the 'Weekly Magazine,' recently begun at Edinburgh by Walter Ruddiman, the nephew of the grammarian. Stuart (and his father, who is believed to have assisted him) had two special reasons for these aggressions: the new grammar was designed to supplant that of their relation Ruddiman, and Adam was besides a great ally of Principal Robertson. In 1772, also, Stuart edited (anonymously) the posthumous work of Francis Stoughton Sullivan, LL.D., entitled 'Lectures on the Feudal and English Laws.'

In 1773 he returned to Edinburgh; and then he and Mr. William Smellie, the printer (a man of talent and considerable literary acquirement), set up together a new monthly periodical, entitled 'The Edinburgh Magazine and Review.' The first number of this publication, which is not to be confounded with the original 'Edinburgh Review' established in 1754, in which Dr. Robertson, Adam Smith, &c. were writers, appeared in October, 1773, the 47th and last in August, 1776. The general spirit of the articles, especially of those written by Stuart, was of such unsparing severity, instigated too, as was conceived, in many cases by his personal resentments, that, notwithstanding the attraction of no common ability, a public feeling was at last aroused against the work, which compelled its conductors to give it up. A list of Stuart's reviews and other communications is given in Kerr's 'Life of Smellie,' i., 403-405. Of the former the most remarkable was an article on the first volume of Henry's 'History of Great Britain,' the first of a series of ferocious attacks on that work by Stuart, of which a full account may be found in Mr. D'Israeli's 'Calamities of Authors.' They were continued in the 'Political Herald' and the 'English Review,' two periodical works in which Stuart engaged when he returned to London some years after this, and the proprietor of which was his countryman Mr. John Murray, the father of the present eminent publisher of the same name. But meanwhile he produced several additional works in his own name while he still remained at Edinburgh; his 'Observations concerning the Public Law and Constitutional History of Scotland,' 8vo., Edinb., 1779 (an attack upon the introductory book of Dr. Robertson's 'History'); his 'History of the Establishment of the Reformation of Religion in Scotland,' 4to., London, 1780; and his 'History of Scotland from the Establishment of the Reformation to the Death of Queen Mary,' 2 vols. 8vo., London, 1782, another attack upon Robertson, founded on his alleged unfair treatment of the Scottish queen, whom Stuart zealously defends from all the charges brought against her. These works all drew considerable attention in their day, but they are now little read; the amount of learning and thought which they contain has not proved sufficient to buoy up the large portion of them composed of inconclusive unsatisfactory speculation, and the sophistry of mere passion and party spirit. They are all written however with much force and vivacity of style. Stuart returned once more to London in 1782; and he appears to have been principally employed in conducting the two publications belonging to Mr. Murray, already mentioned, for the next four years. But jaundice and dropsy, brought on and fed by persevering dissipation, had by the end of this space completely undermined his constitution. He returned to Scotland in the spring or summer of 1786, and died in his father's house at Musselburgh, on the 13th of August in that year.

(Kerr's *Memoirs of Smellie;* D'Israeli's *Calamities of Authors;* Chalmers's *Life of Ruddiman.*)

STUBBE, HENRY, was a remarkable example of temporary celebrity followed by nearly complete neglect and oblivion, the consequence of great natural talents and acquired knowledge not being matched with a sufficiency of judgment, and of there chancing to be little or nothing in a considerable mass of literary produce which has not been superseded by later works or by the progress of discovery. He was the son of a clergyman, and was born at Partney, near Spilsbye in Lincolnshire, 28th February, 1631. He spent his early boyhood in Ireland, whither his father had transferred himself and his family on being taken with a fancy for the doctrines of the Baptists; but after his death the breaking out of the rebellion in 1641 drove the widow and her son back to England, upon which young Stubbe was put to Westminster school, then presided over by Busby, with whom he became a great favourite. In 1649 he was elected a student of Christ Church, Oxford; where, although he made himself many enemies by his conceit and arrogance, he is said to have prosecuted his classical studies with such success, that while still an undergraduate he used to discourse in the public schools in very fluent Greek. He had before going to the University attracted the notice of Sir Harry Vane, from whom he received much substantial kindness; and this connection naturally attached him to the parliamentary cause—for which however he used to declare in after-life that he never had, had any real affection. But for a considerable time he exerted himself with much seeming zeal on that side in various ways. After he had taken his degree of B.A. he went to Scotland in 1653, and served for a couple of years in the army there; and then, having, on returning to Oxford, and taking his master's degree, been made under-librarian of the Bodleian, he got himself turned out after about two years, both from that office and from his studentship, by a succession of violent pamphlets which he published against the existing condition both of church and state, under the titles of 'A Vindication of Sir Harry Vane;' 'An Essay on the Good Old Cause;' and 'Light Shining out of Darkness, with an Apology for the Quakers.' Upon this catastrophe he betook himself to Stratford-on-Avon, and there practised as a physician till the Restoration, when he presented himself to receive confirmation from the hands of his diocesan, and in 1661 was sent out to Jamaica with the title of his majesty's physician for that island; but, finding the climate not to agree with him, he soon returned and re-established himself at Stratford, from which, after some time, he removed to Warwick, where he continued to reside till he met with his death, by being drowned in attempting to make his way across a river between Bath and Bristol, on the 12th of July, 1676. Stubbe, who seems to have had no principle, began to write against his old political friends and his former political

opinions as soon as the king returned; but his only writings after the Restoration that are now remembered are his attacks upon the Royal Society, the principal of which is his answer to Sprat and Glanville, entitled 'Legends no History, or a Specimen of some Animadversions upon the History of the Royal Society; together with the Plus Ultra of Mr. Glanville reduced to a Non Plus,' 4to., 1670. But here too he wasted his powers in a cause with which posterity has not sympathised. Anthony Wood, who was his contemporary at Oxford, has drawn his character graphically enough. He was, Wood says, 'the most noted Latinist and Grecian of his age; was a singular mathematician, and thoroughly read in all political matters, councils, ecclesiastical and profane histories: had a voluble tongue, and seldom hesitated either in public disputes or common discourse: had a voice big and magisterial, and a mind equal to it: was of an high generous nature, scorned money and riches, and the adorers of them; was accounted a very good physician, and excellent in the things belonging to that profession, as botany, anatomy, and chemistry.' Stubbe, with all his vast memory for words and facts, was plainly destitute of the faculty of distinguishing, in a case of any complexity, right from wrong, or truth from falsehood. Wood admits that he altogether wanted even common discretion. 'He was,' he says, 'a very bold man, uttered anything that came into his mind, not only among his companions, but in public coffee-houses, of which he was a great frequenter; and would often speak freely of persons then present, for which he used to be threatened with kicking and beating. He had a hot and restless head, his hair being carrot-coloured, and was ever ready to undergo any enterprise, which was the chief reason that macerated his body almost to a skeleton. He was also a person of no fixed principles; and whether he believed those things which every good Christian doth, 'tis not for me to resolve.' And in fine, Wood concludes by telling us that 'he became a ridicule, and undervalued by sober and knowing scholars, and others too.'

STUBBS, GEORGE, an eminent animal painter and anatomist, was born at Liverpool in 1724, and settled in London. He excelled especially in the portraits of horses. Fuseli observes, 'That his skill in comparative anatomy never suggested to him the propriety of style in forms, if it were not eminently proved by his Phaëton with the Horses of the Sun, would be evident from all his other figures, which, when human, are seldom more than the attendants on some animal; while the style of the animals themselves depended entirely on the individual before him: his tiger, for grandeur, has never been equalled: his lions are, to those of Rubens, what jackals are to lions; but none ever did greater justice to that artificial animal, the race-courser.'

Stubbs completed in 1766 his work 'On the Anatomy of the Horse,' in eighteen tables from nature; and before his death three numbers of another work (which was to have consisted of six), under the title of 'A Comparative Anatomical Exposition of the Structure of the Human Body with that of a Tiger and a common Fowl,' in thirty tables.

There are two pictures by this artist in the Grosvenor Gallery, the property of the Marquis of Westminster: one of them represents Portraits of Brood-Mares in a Landscape; the other, the Grosvenor Hunt. The scene is near Eaton Hall, in which portraits of the late Earl Grosvenor, of his brother, and others are introduced. These pictures have been considered the best works of this artist.

Dr. Waagen, speaking of the first of these two pictures, says, 'I was much pleased at meeting with a picture by this artist, of whose merits I had formed a high idea from engravings, and from his work on the Anatomy of the Horse. It represents horses under the shade of noble oaks: besides the great truth and the profound knowledge in the representation of the horse, it is treated with great ability; and the tone of the sky is very good.'

(Fuseli, *Dictionary of Painters*; Young's *Grosvenor Gallery*; Waagen's *Arts and Artists in England*.)

STUCCO, an Italian word adopted in most other languages, and applied as a general term to plaster of any kind used as a coating for walls, and to give them a finished surface. *Stuccatura*, or stucco-work, is the term similarly employed for all interior ornamental work in imitation of carved stone, so executed, such as the cornices and mouldings of rooms, and the enrichments of ceilings. Stucco was very much employed by the antients, and not merely for coating columns, &c. constructed of brick, but in many instances for covering stone or even marble; for which last purpose it was applied so sparingly as to be no more than a very thin incrustation, for the purpose, it is now supposed, of being painted upon. Recent inquiries into the subject of *Polychromy*, by Semper and others, have put it beyond doubt that the temple of Theseus at Athens, and other edifices of that period, were so painted. It is not improbable that stucco was used by the antients, in such cases, partly to protect the stone from decomposition, for they had the art of preparing it in the greatest perfection, and rendering their stuccoes and mortars almost indestructible.

The stucco used for internal decorative purposes, such as those above mentioned, is a composition of very fine sand, pulverised marble, and gypsum, mixed with water till it is of a proper consistency. Within a short time after being first applied, it begins to set, or gradually harden, in which state it is moulded, and may at length be finished up with metal tools. Even in buildings of the most sumptuous kind, whatever may be their other materials, though marble may be employed for the floors and columns of rooms, the cornices and ornaments of vaultings and ceilings are almost invariably of stucco-work, or else some other artificial composition, such as papier-maché, which is now beginning to be in request, and which has this advantage, that ornaments cast in it can be affixed with very little trouble to a ceiling or other surface originally left plain. Indeed, were it not for stucco or some substitute, it would be hardly possible to introduce any sort of carved work in such situations, such material as stone being out of the question for flat ceilings.

The stucco employed for external work is of a coarser kind, and variously prepared, being now manufactured wholesale as an article of commerce, ready for use, and of which the different sorts are generally distinguished by the name of *cements*. Adam's or Liardet's cement (so called from being that employed by the Adams [Adam], who first of all introduced stucco in this country as a substitute for stones, and from Liardet, who obtained a patent for it, in 1773) is an oil cement, of which the chief ingredients are fine whiting and calcined oyster-shells, well mixed and ground up in a mill with oil. This, if not the cheapest at first, is perhaps one of the best and most economical cements, as the test of about seventy years proves that it will bear this climate for a considerable length without exhibiting marks of decay. Parker's or Roman cement, that now most in vogue, consists chiefly of a preparation of argillaceous limestone found on the coasts of Essex and Kent, and in the Isle of Sheppey. Of Bailey's cement, lime and sharp sand are the principal ingredients; while mastic, or Hamelin's cement, is composed of peroxide of lead and oil. Keene's cement is one of very recent invention, and of very superior quality, taking a surface and polish almost equal to that of the finest marble. It is in fact a species of scagliola, consequently is employed, like that, only for interior decoration.

As an imitation of stone, much will depend upon the skill and care with which stuccoing is executed, on its being made to resemble stone as closely as possible, both as to tint and the grain or surface; and in order to render the deception as complete as possible, it is important, though it is not always done, that lines should be made on the face of the wall, indicating the joints and courses of stone work. If perfectly well executed, stucco will be nearly equal in appearance to stone, and even superior to that of stone of inferior quality. There are some who protest against the use of stucco externally, altogether, as a spurious and meretricious mode of building with sham material; but it is certain that most of Palladio's edifices, and of what are spoken of as the 'marble palaces' of Venice and Rome, are merely faced with stucco. If too the extensive application of stucco in this country, of late years, for architectural purposes, has given rise to a good deal of paltry and flimsy affectation of finery, it has been favourable to architectural design, and promoted a taste for it, by allowing it to be executed where stone would be too expensive a material, or where, if stone were employed, the same extent and degree of enrichment could not be afforded.

STUHLWEISSENBURG, a county in the kingdom of Hungary, is bounded on the north by Comorn, on the east by Pesth, on the south by Tolna, and on the west by Vesprim. The southern and larger portion of the county is flat, with some inconsiderable hills; the northern part is mountainous, being traversed by some branches of the Bakony and Vertes chains. The whole of the right bank of the Danube is high. The principal rivers are, the Danube,

which separates it from Pesth, and the Sarwitz. There are many other smaller streams. The Sarwitz, which has a very slow current, makes many stagnant pools and marshes, which cover many thousand acres of land: an expensive canal has however been formed, by which part of the marshes has been drained and rendered fit for agriculture. The area of the county is 1600 square miles, of which 799,853 acres are stated to be useful land, viz. 360,411 acres arable land, 81,060 pasturage, 23,814 vineyards, 8917 garden-land, and 316,651 forests. The soil is extremely fertile: it produces corn, especially wheat of remarkably fine quality; pulse, garden vegetables, and abundance of fruit. Tobacco, woad, and madder are likewise cultivated. Red and white wines are made in considerable quantity, but they are not much esteemed, because they will not keep. The breed of horses, oxen, and swine is good; but the country is chiefly remarkable for numerous flocks of fine sheep. The rams are highly valued, and numbers of them are purchased for other counties. Beasts of prey, especially wolves, and all kinds of game, are found in abundance in the forests. Fish of various kinds are taken in the rivers and lakes. In the Sarwitz and the marshes there are many crabs, tortoises, wild ducks and geese, and other water-fowl. The population is said not to exceed 130,000, who are descended partly from Slavonians, and partly from Magyar and German settlers. The majority are Roman Catholics; but the Protestants, and especially Calvinists, are numerous.

STUHLWEISSENBURG, the capital of the county, is situated in 47° 12′ N. lat. and 18° 25′ E. long., in a marshy spot near the Sarwitz, and is surrounded with numerous canals for draining the marshes. It has two suburbs, which are surrounded with a deep moat, and connected with the town by bridges. This town has greatly declined from its ancient splendour; and though there are several fine buildings, it has on the whole a mean appearance. It was founded in the eleventh century by King Stephen, was for five hundred years the place where the kings of Hungary were crowned, and where many of them were buried, from Stephen I, who died in 1038, to Zapolya, who died in 1540. From this circumstance it was called Alba Regia or Regalis. It is said to be built on the site of the Roman Floriana. When the contest for the possession of Hungary by the house of Austria began, under the emperor Frederick III., Maximilian I., king of the Romans, took the town in 1490 but was not able to retain it against Bathori. In 1543 it capitulated to the Turks under Soliman the Magnificent. The Turks were defeated in 1593, in the vicinity of the town, by Palfy, Nadasli, and Zrinyi, the generals of the emperor Rudolph II.: but still kept possession of it. In 1601 the duke of Mercoeur and General Russworm took it by storm: Hassan Pasha, who attempted to retake it, was defeated in a great battle; but the garrison having mutinied, it again fell into the hands of the Turks in 1602. When the Turks were at length expelled from Hungary by the armies of Leopold I., the town was taken in 1688 by the elector of Bavaria. The empress Maria Theresa made this town a bishop's see in 1772. The principal public buildings are, the court-house, remarkable for its great extent and fine architecture; the episcopal palace; the palace of Count Schmidegg, in which are the post-office, the coffee-house, and assembly-rooms; and of the six churches, the cathedral, and the church of St. Mary, built by Stephen I. with the spoils taken in war. There are also a gymnasium, a seminary, a normal school, a military academy, and a Hungarian theatre. There are some manufactures of coarse cloth and flannel, but the inhabitants depend for subsistence chiefly on gardening and agriculture. The environs are extremely fertile.

(Hassel; Jenny, *Handbuch für Reisende*; Thiele, *Das Königreich Ungarn*; *Statistisch-Geographische Beschreibung der Königreiche Ungarn, Croatien, Slavonien, &c.*)

STUKELEY, THE REV. WILLIAM, M.D., was descended from an antient Lincolnshire family, and was born at Holbeach in that county, on the 7th of November, 1687. From the grammar-school of his native town he went to Bennet College, Cambridge, in 1703. At this time natural science, as connected with the profession for which he was intended, seems to have been his favourite pursuit; and the chief assistant of his studies was Stephen Hales, afterwards celebrated for his physical investigations and discoveries, who was a member of the same college. Hales and he, we are told, were wont to ramble over Gogmagog Hills and the bogs of Cherry Hunt Moor, gathering simples; Stukeley, who was a ready draughtsman, having added a map of the country to a copy of Ray's Latin Catalogue of the Plants growing around Cambridge, which they used to take with them as their guide. The two friends also applied themselves together to anatomy and chemistry, and performed many curious dissections and experiments. (*Account of Hales*, drawn up from materials furnished by Peter Collinson, F.R.S., in *Annual Register* for 1765.)

Having taken his degree of M.B. in 1709, Stukeley afterwards repaired to London, where he attended St. Thomas's Hospital as a pupil of Dr. Mead; and then he settled as a medical practitioner at Boston, in his native county. In 1717 he removed to London; in 1719 he took his degree of M.D.; in 1720 he was admitted a Fellow of the College of Physicians; but although he appears to have continued to rise in his profession, he left the metropolis in 1726, and, returning once more to Lincolnshire, fixed himself at Grantham. Here he soon acquired great reputation. His health however had been for some years giving way, and in 1729, on the persuasion, it is said, of archbishop Wake, he relinquished medicine and took orders. The same year he was presented by lord chancellor King to the living of All Saints in Stamford; and some time after, having become chaplain to the duke of Ancaster, he received from his grace, in 1739, the living of Somerby, near Grantham, which he seems to have held along with his Stamford preferment. But in 1747 he was presented to the rectory of St. George the Martyr, in Queen Square, London, by the duke of Montague, with whom he had become acquainted some years before, when they were brought together as founders of the Egyptian Society; and this brought him once more up to the metropolis, which, or Kentish Town, in the immediate neighbourhood, continued to be his residence for the rest of his life. He died in the rectory-house, on the 3rd of March, 1765, from a stroke of palsy with which he had been attacked a few days before.

The taste for antiquarian research showed itself in Stukeley at an early age, and occupied much of his leisure even when his chief attention was given to other studies. It is only as a writer on British antiquities that he is now remembered. His only medical publication is a tract entitled 'A Dissertation on the Spleen,' which appeared in 1723, and is said to have been well received. But even before this he had published his first antiquarian work, 'An Account of a Roman Temple (the celebrated Arthur's Oven) and other Antiquities near Graham's Dike in Scotland,' 4to., London, 1720. This was followed by his 'Itinerarium Curiosum, or an Account of the Antiquities and Remarkable Curiosities in Nature or Art observed in Travels through Great Britain;' illustrated with copper-plates, fol., 1724. A second volume, or 'Centuria,' as it is designated, was added to this work from the papers and drawings he left at his death ready for the press; and was given to the world, along with a reprint of the former volume, in 1776. It is of all Stukeley's works the one that is now most sought after. His next publications were his two works on the great druidical or supposed druidical remains in the west of England:—the first, entitled 'Stonehenge and Abury, two Temples restored to the British Druids,' fol., 1740; the second, 'Abury, a Temple of the British Druids,' fol., 1743. [AVEBURY.] A new edition of these two works was published at London, in two vols. folio, in 1838. In 1743 also appeared his 'Palæographia Britannica,' 4to. He produced nothing more except some communications to the 'Archæologia' and the 'Philosophical Transactions,' till, in 1757, he printed, in a separate tract, his account, with extracts, of the work of Richard of Cirencester, 'De Situ Britanniæ,' sent to him as having been recently discovered at Copenhagen, by J. C. Bertram [RICHARD OF CIRENCESTER]; but a more extended account of this work is given in the second or posthumous Centuria of his 'Itinerarium Curiosum,' already noticed. In 1757 appeared, in a quarto volume, one of his most remarkable works, entitled 'Some Account of the Medallic History of Marcus Aurelius Valerius Carausius, Emperor of Britain.' 'I have used his materials,' says Gibbon, in one of his notes, referring to this work, 'and rejected most of his fanciful conjectures.' No antiquarian ever had so lively, not to say licentious a fancy as Stukeley; the idea of the obscure remote past inflamed him like a passion; most even of his descriptions are rather visions than sober relations of what would be perceived by an ordinary eye; and never before or since were such broad continuous webs of specula-

tion woven out of little more than moonshine. He possessed however a great deal of real ingenuity as well as learning; and all his works contain many things that are both curious and valuable, some of them much that would by this time have been irrecoverably lost but for his record of it, although few if any of either his theories or his histories are to be received throughout with implicit faith. His only theological work, we believe, was a collection of Sermons, published in 1760, under the title of 'Palæographia Sacra,' principally occupied with the natural history and botany of the antient world. As a man, Stukeley appears to have been distinguished by a very placid and amiable disposition.

(Hutchinson's *Medical Biography; Notice*, by Collinson, in *Annual Register* for 1765.)

STURGEON. [STURIONIDÆ.]

STURIO'NIDÆ, a family of fishes belonging to the section *Chondropterygii*, the species of which are distinguished from others of the section by the gills being free, as in ordinary fishes, thus differing from the second great division of the fishes having a cartilaginous skeleton, such as the Sharks and Rays, in which the gills are fixed, and have their outer margin attached to the skin. The *Sturionidæ*, or Sturgeon tribe, have moreover but one opening to the gills, and this is protected by an operculum.

Four genera are contained in this family, *Accipenser, Spatularia, Chimæra*, and *Callorhynchus*. To the first of these genera belongs the common sturgeon (*Accipenser Sturio*, Linn.), which is not unfrequently met with in mouths of the English rivers. It is of an elongated form, and has the body protected by numerous indurated plates, which are arranged in longitudinal series, the head is entirely covered by bony plates; the muzzle is elongated, and more or less pointed; and the mouth, which is placed on the under side of the head, is tubular, and destitute of teeth: on the back is a single dorsal fin, which is placed on the hinder third of the fish; the tail is forked, and the upper lobe is the largest, as in the Sharks.

'In the northern part of Europe,' observes Mr. Yarrell, 'this fish is much more numerous than with us, and extensive fisheries are established for its destruction. Caviar is made of the roe of the female; isinglass is obtained from the dense membrane forming the air-bladder; and the flesh besides being preserved by salting and pickling, is in request for the table while fresh, being generally stewed with rich gravy, and the flavour considered to be like that of veal. The flesh, like that of most of the cartilaginous fishes, is more firm and compact than is usual among those of the osseous families.'

Two species of sturgeon have long been distinguished by the fishermen of the Solway Firth, the one with a blunt nose, and the other with a sharp nose: the latter is the most common of the two; the former has recently been described by Dr. Parnell, in the 'Transactions' of the Royal Society of Edinburgh (vol. xiv., pl. 4), and is introduced by Mr. Yarrell, in the Supplement to his 'History of British Fishes.'

Several very distinct species frequent the rivers of Russia, and will be found described and figured by M. A. Loretzky, in the third volume of the 'Transactions' of the Imperial Society of Naturalists at Moscow. Three species are found in the rivers which flow into the Black Sea, and moreover North America possesses species which are peculiar.

The genus *Spatularia* is distinguished by the enormous prolongation of the muzzle, the sides of which are dilated. The general form of the body nearly resembles that of the Sturgeons; but the gills are more open, and the operculum is prolonged into a membranous point behind; the mouth is deeply cleft, and well provided with small teeth; the lobes of the tail are very nearly equal. But one species of this curious genus is known (*Squalus Spatula*, Mauduit), and that is an inhabitant of the Mississippi.

Genus *Chimæra*, Linn.—Although placed in the present section, the *Chimæræ* differ considerably from the sturgeons, and are in fact very nearly allied to the sharks. 'Though in these fishes there is but one apparent gill-opening,' observes Dr. Richardson, in his 'Fauna Boreali-Americana,' 'the gills in reality adhere by a large part of their borders, and there are consequently five holes communicating with the external gill-opening.' They have a rudimentary operculum concealed by the skin; and their jaws, still more reduced than those of the sharks, are furnished with hard plates, four above and two below, in place of teeth. The males are distinguished by trifid bony appendages to the ventral fins. The eggs are large and of a coriaceous texture, and have flattened and hairy margins. The snout, supported like that of the sharks, projects forwards, and is pierced with pores arranged in tolerably regular lines; the anterior dorsal fin is armed with a strong bony spine, and is placed over the pectorals.

In the genus *Chimæra*, as at present restricted, the snout is conical; the second dorsal fin commences immediately behind the first, and extends to the tip of the tail, which is elongated and pointed, and terminates in a long filament: on the under side, the tail is also furnished with a long but narrow fin. Only one species is known, the Northern Chimæra (*Chimæra monstrosa*, Linn.). This fish inhabits the European Seas, and is said to be frequently caught following the shoals of herrings, on which it preys. It is usually about two or three feet in length, and the general colouring of the body is silvery-white, but the upper parts are mottled with brown.

The next genus differs from *Chimæra* chiefly in having the snout terminated by a largish fleshy appendage. The second dorsal fin is placed over the ventrals, and terminates opposite the commencement of the lower tail-fin. The only species known, until very recently, was the Antarctic Chimæra (*Chimæra Callorhynchus* of Linnæus), an inhabitant of the South Seas. A second species of *Callorhynchus* is described by Mr. Bennett under the name *Cal. Smythi*, in the zoological appendix to Beechy's 'Voyage;' and more recently Dr. Richardson describes a species of the present genus (*C. Tasmanius*),* which he regards as distinct. It is from Port Arthur, Van Diemen's Land.

STURM, JOHN, was born on the 1st of October, 1507, at Schleiden in the Eifel, between Treves and Cologne. In 1524 he went to Louvain, where he devoted himself to antient literature, but after a few years' study he entered into partnership with Rutger Rescius, an eminent Greek scholar, who was forming a printing establishment at Louvain for the printing of Greek authors. The only works that are known to have issued from their press are an edition of Homer, and one of Xenophon's 'Memorabilia Socratis,' which appeared in 1529, 4to. In this year Sturm went to Paris, probably with the intention of forming connections for the sale of his publications. But the very favourable reception which he met with at Paris, and the new world which here opened upon him, determined him not to return to Louvain. He began to occupy himself with teaching, and soon obtained permission to set up a school. Sturm had adopted the Lutheran creed before he left Germany, but took care not to avow it in public. At Paris however it appears to have become known to some persons, and the severe regulations in France against Protestantism at last induced him to go to Strassburg, in which city a gymnasium was just established. The office of rector of the school was offered to Sturm, who entered upon it in 1538. Owing to his exertions and the generous support of the city of Strassburg, this gymnasium soon became one of the most flourishing in all Germany, until, in the year 1566, it was raised to the rank of a university, under the management of Sturm. While he was devoting himself with the utmost zeal to his duties as a teacher and rector, he was no less active in promoting the interests of Protestantism. He was sent on various missions concerning religious matters, and was extremely liberal and kind towards all who suffered for their religious opinions. But he showed nothing of a sectarian spirit, and some of his friends, who were staunch Lutherans, began to suspect him of leaning towards the doctrines of Calvin. They openly attacked him in their sermons, the consequence of which was that he gave up attending them. His silence and perseverance excited their anger and hatred. Various charges were at last brought against him, among which it was alleged that he had not been at church or partaken of the Lord's Supper for twenty years. His enemies at length succeeded, in 1583, in persuading the magistrate of Strassburg, on the pretext of his old age, to deprive him of his office, which was given to Melchior Junius, one of his former pupils. Notwithstanding the honourable appearance of his dismissal, and although he was left in the enjoyment of his former salary, he keenly felt the wrong which was done to him. His strength rapidly declined, and a few years before his death, which took place on the 3rd of March, 1589, he lost his sight.

Sturm was one of the most amiable, benevolent, and

* 'Proceedings of the Zoological Society,' for March, 1840, p. 29.

learned men of the age. He went so far in his liberal support of persecuted Protestants, that he became involved in great pecuniary difficulties; but he was far from being a vehement sectarian. He appreciated the merits of every man, whatever might be his religious opinions, and he was no less esteemed by Roman Catholic prelates, than by the moderate party among the Protestants. As a teacher he was eminently successful. On account of his great knowledge of rhetoric, and his elegant Latin style, he was called the German Cicero. His works, all of which are written in Latin, are very numerous. The following are the most important:—'De Literarum Ludis recte aperiendis,' Strassburg, 1538, 4to.; 'In Partitiones Ciceronis Oratorias Dialogi Quatuor,' Strassburg, 1539, 8vo.; 'M. Tullii Ciceronis Opera Omnia, editio post Naugerianam et Victorianam emendata à Jo. Sturmio,' Strassburg, 1540, 9 vols. 8vo., often reprinted with corrections and emendations; 'Prolegomena, hoc est, Praefationes in optimos quosque utriusque Linguae Scriptores,' Zürich, 1565, 8vo.; 'De Universa Ratione Elocutionis Rhetoricae Libri Quatuor,' Strassburg, 1576, 8vo. (this work, which in reality only consists of three books, is a very elaborate and systematic commentary on the rhetorician Hermogenes); 'Anti-Pappi Quatuor,' Neustadt, 1580, &c., 4to. (this work contains his theological controversies with Pappus, Osiander, and others). His treatises on education have been reprinted in several collections of works on this subject.

(Jöcher, *Allgem. Gelehrt. Lex.*, iv., p. 910, &c.; Saxius, *Onom.*, iii., p. 152; *Biographie Universelle.*)

STURM, JOHN CHRISTOPHER, a German mathematician and natural philosopher, was born at Hippelstein, in Bavaria, November 3, 1635. His father, who was master of the wardrobe to the elector of Bavaria, having been ruined by the wars, the youth was indebted for the benefits of a good education to the benevolence of Daniel Wulfer, a clergyman of Nürnberg, who placed him at a school in that city, where, during eight years, he was engaged in the study of the antient languages and such of the sciences as were then taught. Having made considerable progress, young Sturm was sent by his benefactor to the university of Jena, where he took his degrees; and in 1660 he went to study at Leyden. He remained there only one year, and then he returned to Jena, where he qualified himself for the church. He was appointed to the ministry for one of the parishes in the territory of Ettingen, where he continued to perform the duty till 1669, when, through the interest of his friends, he was appointed professor of mathematics in the university of Altdorf, in Franconia. This post he held during thirty-four years, and it is said that he was the first who introduced, in the gymnasia and the common schools of Germany, the practice of giving instructions in the elements of useful science to the children of the working classes.

Sturm had been educated in the philosophy of Aristotle, but in his visit to Holland he became acquainted with that of Descartes; and, after a vain effort to reconcile the principles of the antient with those of the modern physics, he formed for himself a species of philosophy by selecting whatever, in either, appeared most consonant to nature and reason. This philosophy he endeavoured to introduce into the schools of his country; and though he did not wholly succeed, he contributed much to the general diffusion of a knowledge of the physical sciences in the north of Europe.

He died December 26, 1703, leaving a son, Leonard Christopher Sturm, who became an architect.

The principal works of Sturm are, 'Collegium Experimentale sive Curiosum, in quo primaria hujus seculi Inventa et Experimenta Physico-mathematica An. 1672,' Nürnberg, 1676, 2 vols. 4to.; 'Cometarum Natura, Motus, et Origo, secundum Hevelii et Petiti Hypotheses,' Altdorf, 1677, 4to; 'Mathesis Enucleata,' 1 vol. 8vo.; 'Mathesis Juvenilis,' 2 vols. 8vo., of which the second contains a tract entitled 'Scientia Cosmica, sive Astronomica, Spherica, et Theorica Tabulis comprehensa,' Nürnberg, 1684: 'Physicæ Conciliatricis Conamina,' Nürnberg, 1685; 'Philosophia Eclectica,' Nürnberg, 1685, being a collection of the principal dissertations before published on the different systems of philosophy. Sturm also published a translation in Latin of the 'Hydraulic Architecture' of Bockler; a German translation of Archimedes; and a collection of letters to Dr. Henry More of Cambridge, on the weight and elasticity of the air. In 1684 he published a second part of the collection of discoveries made up to that time; and editions of both parts, together with the letters to Dr. More, were published in 1701 and 1715; these contain many curious experiments.

STURM, CHRISTOPH CHRISTIAN, was born on the 25th of January, 1750, at Augsburg. He studied theology at Jena and Halle, and was subsequently appointed preacher at Magdeburg. In 1778 he obtained the offices of pastor at the church of St. Peter, and of Scholarchus, at Hamburg. His sincere piety, his zeal as a religious instructor of the people, and his learning gained for him the love and esteem of his flock. His leading principle was that a preacher should render his knowledge of true religion and morality fruitful in his own actions before attempting to effect the same in others by his instruction: and his whole life, which is marked by scarcely any incidents, was only characterised by the honest endeavour to carry his principle into practice. He died on the 26th of August, 1786.

Sturm wrote many religious works, which are more of a practical than of a scientific character. The following are the most important:—'Der Christ in der Einsamkeit,' Halle, 1763; 'Der Christ am Sonntage,' 1764, &c.; 'Unterhaltungen mit Gott in den Morgenstunden auf jeden Tag des Jahres,' 1768, 2 vols. 8vo., and often reprinted; 'Betrachtungen über die Werke Gottes im Reiche der Natur und der Vorsehung auf alle Tage des Jahres,' 1785. This work has been translated into most of the European languages, and also into English by Clarke, under the title of 'Reflections on the Works of God,' &c. The numerous editions of this translation show that the work has been very popular in England. Sturm also published a considerable number of sermons, and among them a collection of sermons for children: 'Predigten für Kinder von reiferem Alter,' Leipzig, 1774, 2 vols. 8vo. Sturm also occupies a considerable rank among the writers of sacred poetry, which he published in four collections: 'Gebete und Lieder für Kinder,' 1776; 'Gesangbuch für das reifere Alter,' 1777; 'Lieder für das Herz,' 1787; and 'Gesangbuch für Gartenfreunde,' all of which breathe the purest piety. Many of his sacred songs have been incorporated into the hymn-books which are used in the Protestant churches of Germany.

STURM'S THEOREM. There is a branch of the theory of equations, containing the celebrated theorems of Descartes, Fourier, and Sturm, which it is advisable to place in an article by itself, and the present heading has been chosen because Sturm's theorem is at once the most conclusive and the latest of the three. It has long been a problem of much interest and notoriety to find, in a given equation, how many roots, if any, are contained between two given limits: how many roots are positive, how many negative, how many imaginary.

The first step towards the solution of the preceding problem was made by Descartes, though it is asserted by Cossali and Libri, that Cardan came very near to the same step. The former, after collecting a table of Cardan's cases, and putting them in a form which Cardan did not use (an equation with 0 on the second side), then says that an analyst who should look at this table would be able to rise to Descartes's theorem. This is true enough, but it does not prove that Cardan either could or did make the invention, but the contrary. All the world knows that mathematical discoveries are recognised often enough by analysts of a later day, in rudiments from which the fabricators of them could evolve nothing.

The theorem of Descartes, expressed in his own words, is as follows (*Geometria*, lib. iii.): 'Ex quibus etiam cognoscitur, quot veræ et quot falsæ radices in unaquaque Æquatione haberi possint. Nimirum, tot in ea veras haberi posse, quot variationes reperiuntur signorum + et −; et tot falsas quot vicibus ibidem deprehenduntur duo signa +, vel duo signa −, quæ se invicem sequuntur.' That is, that an equation may have as many positive roots as there are changes of sign in passing from term to term, and as many negative roots as there are continuations of sign; but not more of either kind. It has been doubted whether Descartes knew the true meaning of his own theorem as to the case of imaginary roots; this doubt is as early as the time of Descartes himself, who replies in a letter which we cannot find by means of Rabuel's reference to it. This is however of little consequence, as the following sentence (also from the Geometry) shows in what manner Descartes understood his own words: 'Cæterum radices tam veræ quam falsæ non semper sunt reales, sed aliquando

[illegible] integer [illegible]; [illegible] semper quidem in qualibet Equatione [illegible] imaginariæ licet: verum nulla interdum est quantitas quæ illis, quas imaginamur, respondet' [illegible] then that Descartes not only remembered the limitation of the theorem arising from the possible existence of imaginary roots, but proposed to divide those last [illegible] themselves into two classes corresponding to the [illegible] false (or positive and negative) of the real roots. The next step was made by De Gua (1741), who showed that the roots of an algebraical equation $\phi x=0$ [illegible] real [illegible] the roots of the derived equations $\phi' x=0$, $\phi'' x=0$, &c. are also all real: $\phi' x$, $\phi'' x$, &c. being the derived functions, or differential coefficients, of ϕx. [illegible] the conditions of the reality of all [illegible] (Lagrange, *Rés. des Équ. Numér.*, note [illegible] &c. [illegible] 27.)

[illegible] would be perfect if the roots of equations were always real. For example, take $x^2-13x+40=0$. [illegible] both positive: write $x+6$ for x [illegible], and we have $x^2-x-2=0$, of which the roots are less by 6 than those of the former [illegible] in the second equation, one root is negative [illegible] positive: consequently the roots of the first equation [illegible] greater and one less than 6. In the same [illegible] more complicated case might be treated.

The theorem of Descartes, and the notion derived from [illegible] order of signs of coefficients regulates the signs [illegible] roots; with the step made by De Gua, and the notion [illegible], namely, that the derived functions must be [illegible] whether the roots of an equation [illegible] and the common theory of equal roots, [illegible] when $\phi x=0$ has m equal roots, $m-1$ of its [illegible] (neither more nor fewer) vanish at the [illegible] the same root,—were the hints on which Fourier was able to make an advance upon his [illegible]. The coefficients of the equation are themselves [illegible] the derived functions, on the [illegible]. Thus, if $\phi x=3x^3-7x^2+11x+4$, we have

$$\phi 0=4,\quad \frac{\phi' 0}{1}=11,\quad \frac{\phi'' 0}{1.2}=-7,\quad \frac{\phi''' 0}{1.2.3}=3.$$

Let ϕx, $\phi_1 x$, $\phi_2 x$, &c. be the function in question and its [illegible] functions. If we make x great enough and negative (say infinite and negative), the signs of these functions [illegible] alternate, that is, the series yields nothing but changes of sign in passing from term to term. But if we make x great enough and positive (say infinite and positive), the series yields nothing but permanences of sign. Thus, in the preceding expression we have

	$x=-\infty$	$x=0$	$x=+\infty$
ϕx	$-$	$+$	$+$
$\phi_1 x$	$+$	$+$	$+$
$\phi_2 x$	$-$	$-$	$+$
$\phi_3 x$	$+$	$+$	$+$
	nothing but changes.	two changes.	no changes.

$$\phi x=3x^3-7x^2+11x+4,\quad \phi_1 x=9x^2-14x+11,$$
$$\phi_2 x=9x-7,\quad \phi_3 x=3.$$

Now Descartes's theorem tells us that there *may* be *one* negative and *two* positive roots, and we see that in passing from $x=-\infty$ to $x=0$, or through the whole range of negative quantity, there is *one* change of signs lost; while in passing from $x=0$ to $x=+\infty$, or through the whole range of positive quantity, *two* changes of sign are lost. Fourier's theorem would suggest itself as highly probable to any one who put Descartes's theorem in the preceding form: it is as follows:—When $x=a$, let the signs of ϕa, $\phi_1 a$, $\phi_2 a$, &c. be [illegible], and let this be called the criterion series, or simply the criterion. Then in passing from $x=a$, the less, to $x=b$, the greater (greater and less being understood in the algebraical sense), the criterion never acquires changes of sign, though it may lose them. When m changes of sign are lost in the criterion in passing from $x=a$, the less, to $x=b$, the greater, it follows that there are either m real roots of the equation lying between a and b, or some number, p, of pairs of imaginary roots, and $m-2p$ real roots lying between a and b. If m be odd, there must be at least one real root lying between a and b. And if no changes of sign be lost in passing from a to b, there is certainly no root lying between a and b. For example, examine the preceding function and its derivatives when $x=-1$ and $x=+1$. In the former case the criterion is $-+-+$ (three changes), and in the latter $++++$ (no changes). Three changes then are lost to the criterion in passing from -1 to $+1$: so that there are either three real roots, all lying between -1 and $+1$: or one such real root and two imaginary roots. Again, in passing from -1 to 0, one change is lost: there is certainly then one negative root between -1 and 0. The remaining roots are then either both imaginary, or positive, and lying between 0 and 1: the least consideration of the equation will show that the former is the case.

Fourier's theorem is proved as follows:—changes of sign take place only when quantities become nothing or infinite; those before us cannot become infinite, and therefore the criterion can never be disturbed except when one or more of the set ϕx, $\phi_1 x$, &c. vanish. Now when any function ψx, vanishes, say at $x=a$, its previous sign must have been the contrary of that of its derived function, and its subsequent sign the same: that is, in passing from $a-h$ to $a+h$, h being very small, $\psi' x\times\psi x$ must pass from negative to positive. An algebraical proof may be given of this, but none which in clearness comes near to the following. The function $\psi' x\times\psi x$ is the derived function or differential coefficient of $\frac{1}{2}(\psi x)^2$, a positive quantity. Now if $\psi a=0$, $\frac{1}{2}(\psi x)^2$ must diminish (being positive) from $x=a-h$ to $x=a$, and increase from $x=a$ to $x=a+h$. But a differential coefficient is negative when its function diminishes with an increase of the variable, and positive when its function increases with an increase of the variable. Consequently $\psi' x\times\psi x$ is negative from $x=a-h$ to $x=a$, and positive from $x=a$ to $x=a+h$; as asserted. We now proceed to the proof of the theorem.

1. When $x=-\infty$, the criterion is $+-+-$ &c. or $-+-+$ &c.: and when $x=+\infty$, it is $+++$ &c. or $---$ &c. This follows immediately from the nature of the functions ϕx, $\phi_1 x$, &c., in which, when x is numerically great enough, the sign is always governed by that of its highest term. Thus, in some place or places, as many changes are certainly lost as there are units in the dimension of ϕx, *neither more nor fewer*.

2. When x passes through a root of ϕx, as many changes are lost as there are roots of ϕx equal to that root. Let there be only one root equal to a, so that $\phi_1 a$ does not vanish. We have then one or other of the following:—

	$x=a-h$	$x=a$	$x=a+h$		$x=a-h$	$x=a$	$x=a+h$
ϕx	$(+)$	0	$(-)$	ϕx	$(-)$	0	$(+)$
$\phi_1 x$	$-$	$-$	$-$	$\phi_1 x$	$+$	$+$	$+$
	One change lost.				One change lost.		

The signs in parentheses are those which follow from the theorem above proved. $\phi_1 x$ cannot change its sign in the process, for by hypothesis it does not vanish when $x=a$, and we take h so small that there shall be no root of $\phi_1 x$ between $a-h$ and $a+h$. At $x=a-h$, we must have $\phi_1 x\times\phi x$ negative, and at $x=a+h$ we must have it positive, by the theorem; which gives the signs in parentheses as marked.

Now let there be, say five roots equal to a, or let ϕa, $\phi_1 a$, $\phi_2 a$, $\phi_3 a$, $\phi_4 a$ all vanish, $\phi_5 a$ not vanishing. We must have then one or other of the following:—

	$x=a-h$	$x=a$	$x=a+h$		$x=a-h$	$x=a$	$x=a+h$
ϕx	$+$	0	$-$	ϕx	$-$	0	$+$
$\phi_1 x$	$-$	0	$-$	$\phi_1 x$	$+$	0	$+$
$\phi_2 x$	$+$	0	$-$	$\phi_2 x$	$-$	0	$+$
$\phi_3 x$	$-$	0	$-$	$\phi_3 x$	$+$	0	$+$
$\phi_4 x$	$+$	0	$-$	$\phi_4 x$	$-$	0	$+$
$\phi_5 x$	$-$	$-$	$-$	$\phi_5 x$	$+$	$+$	$+$
	Five changes lost.				Five changes lost.		

All the signs except those in the lowest line are dictated by the preliminary theorem. Thus $\phi_5 x$, in the first case, is negative by hypothesis; now $\phi_5 x$ is $\phi'_4 x\div 5$, so that $\phi_5 x\times\phi_4 x$ must be negative before $\phi_4 x$ vanishes, and positive afterwards. Hence $\phi_5 x$ continuing negative, $\phi_4 x$ must change from positive to negative. Again, $\phi_4 x\times\phi_3 x$ makes a similar change. The least consideration will show that, the signs in the lowest line being given, those in all the upper ones must be as written.

3. When intermediate functions vanish, changes of sign are never gained, but only lost; and are never lost but in even numbers. Suppose, for instance, that $\phi_1 a$ vanishes, but not ϕa nor $\phi_2 a$. We have then one of the four following:—

	$x=a-h$	$x=a$	$x=a+h$		$x=a-h$	$x=a$	$x=a+h$
$\phi_1 x$	+	+	+	ϕx	−	−	−
$\phi_2 x$	−	0	−	$\phi_1 x$	+	0	−
$\phi_3 x$	−	−	−	$\phi_2 x$	−	−	−
	No change lost.*				*Two* changes lost.		
$\phi_2 x$	−	−	−	ϕx	+	+	+
$\phi_3 x$	−	0	+	$\phi_1 x$	−	0	+
$\phi_4 x$	+	+	+	$\phi_2 x$	+	+	+
	No change lost.*				*Two* changes lost.		

The signs in the middle lines are dictated by the preliminary theorem. Next let $\phi_4 a$, $\phi_5 a$, $\phi_6 a$, $\phi_7 a$ vanish, but not $\phi_3 a$ nor $\phi_8 a$. We have then, by the preliminary theorem, one or other of the four following:—

	$x=a-h$	$x=a$	$x=a+h$		$x=a-h$	$x=a$	$x=a+h$
$\phi_3 x$	+	+	+	$\phi_3 x$	−	−	−
$\phi_4 x$	−	0	−	$\phi_4 x$	−	0	−
$\phi_5 x$	+	0	−	$\phi_5 x$	+	0	−
$\phi_6 x$	−	0	−	$\phi_6 x$	−	0	−
$\phi_7 x$	+	0	−	$\phi_7 x$	+*	0	−
$\phi_8 x$	−	−	−	$\phi_8 x$	−	−	−
	Four changes lost.				Four changes lost.		
$\phi_3 x$	−	−	−	$\phi_3 x$	+	+	+
$\phi_4 x$	+	0	+	$\phi_4 x$	+	0	+
$\phi_5 x$	−	0	+	$\phi_5 x$	−	0	+
$\phi_6 x$	+	0	+	$\phi_6 x$	+	0	+
$\phi_7 x$	−	0	+	$\phi_7 x$	−	0	+
$\phi_8 x$	+	+	+	$\phi_8 x$	+	+	+
	Four changes lost.				Four changes lost.		

The same conclusions will be found from other cases, and we have now examined every way in which the criterion can undergo an alteration in the order of the signs of which it is composed. And since, the function being of n dimensions, there are altogether n changes, and n only, to lose, it follows that every pair of signs lost by the vanishing of any of the derived functions, in any internal part of the criterion, shows that there must be two imaginary roots: for there must be n roots only, every root must be accompanied by a change lost at the head of the criterion, and every loss of changes which takes place anywhere else diminishes the number which can take place at the head. Again, since losses other than at the head of the criterion must take place in even numbers, it follows that of any odd number of losses, one must have been effected at the head, or must have arisen from a real root; or if not one, some other odd number.

The manner in which the changes of sign take place is as follows:— When $x=-\infty$, or even when it is numerically greater than any negative root, the criterion presents nothing but changes. Alterations of the criterion consist in: 1, Loss of one or more changes at the head of the criterion (showing real roots); 2. loss of changes in even numbers in the middle of the criterion (showing imaginary roots); 3, elevation of changes, or alteration of their place in a direction towards the head of the criterion. This last takes place only when an *odd* number of derived functions vanishes, the including functions (preceding and following) having different signs. As soon as a root has been passed, there is a permanency ++ or −− at the head of the criterion: before another root is arrived at, this permanence must have become a change, since a change there must then be at the head to be lost in passing through the root. Hence it follows that between two roots of $\phi x=0$, there must lie a root of $\phi' x=0$; and this root is either single, triple, quintuple, &c., but not double, quadruple, &c.

For example, let $\phi x=x^4-7x^3+15x^2-10x+2$,
$\phi_1 x=4x^3-21x^2+30x-10$, $\phi_2 x=6x^2-21x+15$,
$\phi_3 x=4x-7$, $\phi_4 x=1$.

There are no negative roots, as is obvious from their being nothing but changes among the coefficients; if we construct the criteria for $x=0$, 1, 2, 3, and 4, we find the following results:—

	0	1	2	3	4
ϕx	+	+	+	−	+
$\phi_1 x$	−	+	−	−	+
$\phi_2 x$	+	0	−	+	+
$\phi_3 x$	−	−	+	+	+
$\phi_4 x$	+	+	+	+	+

* Observe that in these cases a change is removed to a higher place in the series, nearer to the head of the criterion.

When $x=0$, the criterion shows four changes; when $x=1$, it is indefinite, owing to $\phi_2 1=0$. But immediately before $x=1$, $\phi_2 x$ must, by the preliminary theorem, have the sign contrary to that of $\phi_3 x$, or the sign +; consequently at $x=1-h$, however small h may be, the criterion has + + + − +. Two changes of sign are therefore lost in passing from $x=0$ to $x=1$, and there are either two real roots between 0 and 1, or two imaginary roots. To try this further, let $x=\frac{1}{2}$, the criterion of which is − + + − +; so that there is one root between 0 and $\frac{1}{2}$, and another between $\frac{1}{2}$ and 1. When $x=1+h$, the criterion is + + − − +, so that there is no root between 1 and 2. Lastly there is one root between 2 and 3, and one between 3 and 4.

The theorem of Fourier, though very convenient in practice, is defective in theory, as requiring an unlimited number of trials. If two roots were very nearly equal, it would require very minute subdivision of the interval in which they are first found to lie, to distinguish them from a pair of imaginary roots. This theorem was not published till 1831, in Fourier's posthumous work, but its author had made his methods known, and among others to M. Sturm, a young Genevese, employed in the bureau of M. de Férussac, editor of the bulletin which bore his name, now a member of the Institute, and enjoying a reputation which may excuse this mention of the circumstances of his private life. Sturm applied himself to the detection of functions which should stand in the place of ϕx, $\phi_1 x$, $\phi_2 x$, &c., in such manner that the criterion formed from them, in the same way as in Fourier's theorem, should never lose a change of signs except in passing through a real root. In this he signally succeeded: and thus, though his theorem presents great practical prolixity of detail, he furnished a complete solution of the difficulty which had occupied analysts since the time of Descartes. This theorem may be proved as follows:—

Let there be any number of functions $V, V_1, V_2, \ldots V_r$, the last of which is a constant independent of x, and all but the last functions of x. Let them be connected together by the equations—

$$V=P_1V_1-V_2,$$
$$V_1=P_2V_2-V_3,$$
$$V_2=P_3V_3-V_4,$$
$$\cdots\cdots\cdots$$
$$V_{r-2}=P_{r-1}V_{r-1}-V_r$$

$P_1 P_2$, &c. being any functions of x, which do not become infinite when $V_1 V_2$, &c. vanish. From this it follows, first, that no two consecutive functions of the set V, V_1, &c. can vanish together: for if V_2 and V_3, for instance, vanished together, the third equation shows that V_4 would also vanish, the fourth that V_5 would vanish, and so on: consequently V_r, a given constant, also vanishes, which is absurd. Secondly, when any one after V vanishes, the preceding and following must have different signs; for $V_1=0$ gives $V=-V_2$, $V_2=0$ gives $V_1=-V_3$, &c. Now call the signs of V, V_1, &c. the criterion, and let $V=0$ when $x=a$, there being only one root of that value, so that V changes sign in passing from $x=a-h$ to $x=a+h$. Since V_1 does not vanish with V, we have one of the four cases following:—

	$x=a-h$	$x=a$	$x=a+h$	$x=a-h$	$x=a$	$x=a+h$
V	−	0	+	+	0	−
V_1	−	−	−	−	−	−
V	−	0	+	+	0	−
V_1	+	+	+	+	+	+

If V_1 be the derived function of V, only the second or third cases can happen, by the theorem so often used in the preceding part of this article; so that a change of sign must be lost at the head of the criterion for every single root of $V=0$. Nor will any change of sign ever be gained or lost in any other manner: for suppose $x=a$ gives $V_4=0$, for instance, then V_3 and V_5 have different signs, and in passing from $x=a-h$ to $x=a+h$, if each be so small that no root of V_3 or V_5 lies between $a+h$ and $a-h$, we must have one of the eight following cases:—

	$x=a-h$	$x=a$	$x=a+h$	$x=a-h$	$x=a$	$x=a+h$
V_3	−	−	−	+	+	+
V_4	±	0	±	±	0	±
V_5	+	+	+	−	−	−

In no one of these is any change of sign lost, or any thing except a change and a permanence when $x=a-h$, and a

change and a permanence, in a different order perhaps, when $x=a+h$. Consequently, if in passing from $x=a$, the less, to $x=b$, the greater, it appear that no changes of sign are lost, it is certain that there must have been no real root of $V=0$ between $x=a$ and $x=b$.

Now, V_1 being the derived function of V, it remains to find V_2, V_3, &c. Divide V by V_1, which is of one dimension lower, and we have a quotient, say P_1, and a remainder R_1. Then $V=P_1 V_1+R$ or $V_2=-R$. Again, divide V_1 by V_2, giving a quotient P_2, and a remainder R_2: we have then $V_1=P_2 V_2+R_2$ or $V_3=-R_2$; and so on. It appears, then, that V_1 being the derived function of V, we must proceed as in finding the greatest common measure of V and V_1, only changing the sign of every remainder as fast as it is obtained. In order that the last, V_r, may be a finite constant, it is requisite that there should be no equal roots. We must then suppose the equal roots to be separated beforehand, as in the usual method. In fact, this very process of finding the greatest common measure, with or without change of sign in the remainders, will first detect the equal roots, if any. It is important to remark, that at any step multiplication by any positive quantity is allowable, the signs (the only things we have to do with) not being in any case altered by such multiplication.

In Involution and Evolution a method of performing the operations required in Sturm's theorem was proposed, which avoids useless writing. Mr. Young (*Math. Dissertations*, p. 143) has since proposed another, of much the same degree of abbreviation. Sturm's theorem however requires so much operation, that there can be little doubt of that of Fourier being a more easy mode of working any particular case. It is not however as a key to the mere numerical solution of equations that either of these theorems must be viewed: the insight which they give into the nature of equations, and still more that which they are likely hereafter to give (for neither is more than a germ), will render them both important steps in the progress of algebra.

Since all that is necessary to the theorem is that the last function V_r should retain one sign, and not vanish, we may stop in the process when we arrive at any function of which all the roots are known, or can be discovered, to be impossible. And it is easily shown that even when there are equal roots, so that the last, V_r, is neither constant, nor always of the same sign, the theorem still remains true, so far as to give the number of ***different*** roots which lie between any two given limits, without any information as to the number of times which each root should be repeated.

For instance, in the article cited we find

$$V=x^4-3x^3-2x^2+x-3$$
$$V_1=4x^3-9x^2-4x+1$$
$$V_2=43x^2+45$$

We need not go further, for V_2 has none but imaginary roots. Now, when $x=-\infty$, the criterion is $+-+$; when $x=0$, it is $-++$; and when $x=+\infty$, $+++$. Consequently there is one negative root, one positive root, and a pair of imaginary roots.

The following example is from Mr. Young (p. 191): it is an instance given by Fourier in illustration of his own method, and Sturm's is applied to it by Mr. Young, to show the superior certainty of the latter. Of that certainty no one can doubt, but the process exhibited in the page cited is such as will never come into general use unless the work can be made more easy:—

$$V=x^7-2x^5-3x^3+4x^2-5x+6$$
$$V_1=7x^6-10x^4-9x^2+8x-5$$
$$V_2=2x^5+6x^3-10x^2+15x-21$$
$$V_3=52x^4-70x^3+123x^2-163x+10$$
$$V_4=-4403x^3+8862x^2-19810x+20531$$
$$V_5=200865x^2+489790x-1169472$$
$$V_6=187355x-270632$$
$$V_7=\text{ a positive constant.}$$

Here the criteria for $x=-\infty$, $x=0$, $x=+\infty$ are

$x=-\infty$ $-+-+++-+$ five changes
$x=0$ $+--++--+$ four changes
$x=+\infty$ $++++-+++$ two changes.

There are then one negative root and two positive roots, and therefore four imaginary ones. The reader will easily find that the positive roots lie between 1 and 2, and the negative root between -1 and -2. The exhibition of the process, leaving out the actual performance of multiplications, has 400 figures in Mr. Young's work. Fourier has merely written down the derived functions, which is done at sight and formed the criteria for $x=-10$, $x=-1$, $x=-h$, $x=0$, $x=+h$, $x=1$, $x=10$, which may all be done at sight also. From this he finds that there must be one negative root between -1 and -10, that there may be two roots between 0 and 1, and two more between 1 and 10. All this might be done before V_4 could be found and written down as above. It is to be hoped either that Fourier's theorem will be completed by the addition of a test for imaginary roots, or that Sturm's functions will be exchanged for others of less complicated operation. But in the meanwhile it must be remembered that Fourier, Sturm, and Horner have, in thirty years, completely changed the aspect of the solution of numerical equations: at the beginning of the period mentioned, it would have been thought too good to expect that any certain method of predicting, or easy one of calculating, the roots of such equations, should be found, after the failure of all analysts from Des Cartes and Newton down to Euler and Lagrange, the best heads of France and England, Germany and Italy. It is a lesson against despairing of the attainment of any result, however illustrious the investigators who have not succeeded, and also against imagining that the hints of preceding ages are exhausted. All the contents of the present article arise out of a new mode of looking at the theorem which Des Cartes gave two hundred years ago.

STURMINSTER. [Dorsetshire.]

STU'RNIDÆ, Mr. Vigors's name for the *Starling Family*, belonging to his order Insessores.

Linnæus placed his genus *Sturnus*, consisting of only five species, among which the Water-Ouzel appears as *Sturnus Cinclus*, between *Alauda* and *Turdus*, in his order *Passeres*. Cuvier arranges the Starlings between the *Cassiques* (*Cassicus*) and the Crows (*Corvus*).

Mr. Vigors, who assigns to the *Sturnidæ* a place between the *Fringillidæ* and the *Corvidæ*; in his Conirostres, observes that this family embraces a considerable number of groups, approaching each other in their gregarious and migratory habits. They are, he remarks, found in every part of the globe united in large flocks, carrying destruction among the cultivated fields, and following herds of cattle for the sake of the insects or grains which they may pick up from their bodies or in their neighbourhood. 'In addition to the American genus *Icterus*,' continues Mr. Vigors, 'and the contiguous genera *Cassicus* and *Xanthornus* of M. Brisson, together with *Pendulinus*, Vieill., and several corresponding groups, we may observe the genus *Amblyramphus*, Leach, united to the family, as also the *Buphaga*, Linn., and *Pastor* and *Lamprotornis*, which M. Temminck has separated from the *Thrushes*. The whole of the family, united by their manners and the straight and conical form of the beak, the ridge of which passes back to some extent over the forehead, may be observed, by those who cast even a casual glance over the three adjoining groups, to hold an intermediate rank between the weaker conformation of the *Fringillidæ* and the more powerful structure of the *Corvidæ*.' And he passes into the family of *Corvidæ* by the genus *Nucifraga*. [Nutcracker.]

Such is Mr. Vigors's opinion, expressed in his paper on the *Affinities which connect the Orders and Families of Birds*. (*Linn. Trans.*, vol. xiv.)

Mr. Swainson proceeds from the Crows to the Starlings, but he acknowledges that the unarranged state of the last group prevents him from knowing the genus by which this passage is truly effected. He remarks that the various birds assimilated by ornithologists to our European Starling are generally of the same size, and that they appear in fact like a smaller race of crows, which they very much resemble in manners and in structure; in the latter respect they are, he observes, evidently much weaker; and he goes on to notice their habits of seeking their food generally upon the ground, of living in societies, and of preferring plains frequented by cattle. The three principal groups he thinks well characterised. 'In the first the margins of the bill form a distinct angle at the base, which is very wide; the gape extends beneath the eye, and the tips are slightly notched: these are the true starlings (*Sturninæ*). In the second the bill is shorter, more compressed, and very much resembles that of a thrush, being almost destitute of the basal angle: this subfamily comprehends the true grakles (*Lamprotorninæ*), and is remarkable for the metallic lustre of its dark-coloured plumage. The third or aberrant division includes the boat tails (*Scaphidurinæ*), the hang-nests (*Icterinæ*), and the maize-birds (*Agelainæ*), all of which

are characterised by a perfectly entire finch-like bill, more or less conic, but of different lengths.'

In the *Scaphidurinæ*, with which Mr. Swainson commences, we have, he remarks, the largest birds in the whole family; those in short which even a scientific observer might easily mistake for real crows. Their name is given to them from the singular structure of their graduated tail, which becomes so concave on its upper surface by the oblique folding on its sides, as to resemble a boat in form. Mr. Swainson, after stating that all the true species of this group are natives of America, and resemble the crows in the glossy blackness of their plumage, expresses his opinion that they are the rasorial division of the family. But, he adds, there is a bird from New Guinea, *Astrapia gularis*, Vieill. [CORVIDÆ, vol. viii, p. 72], which, from exhibiting the greatest development of this structure, might be taken for the type, if its bill and general habit did not evince an approximation to the *Lamprotorninæ*. *Astrapia*, he remarks, had been associated by all writers, except M. Temminck and M. Vieillot, with the Paradise-birds, from the uncommon brilliancy of its plumage.

The next subfamily, or *Lamprotorninæ*, comprise, according to Mr. Swainson, many smaller groups whose characters have not yet been sufficiently investigated; whilst others, which he conceives to belong to this family, have been placed with the crows. He does not seem altogether satisfied with the position which he has assigned to *Astrapia*, for he remarks that this magnificent bird, but for its long boat-shaped tail, would certainly be ranked with this group, f which, after all, he thinks that it may probably prove to the rasorial genus. He then sums up the chief peculiarities of the grakles, viz. the strong thrush-like bill, generally notched, but never angulated at the base, and the remarkably large and stout feet, and the general blackness of their plumage relieved by the most beautiful metallic lustres of green and blue. The whole group appears to him to be confined to the tropics of Asia and Africa, where, he thinks, they seem to represent the boat-tails. To this group he removes the Australian Satin birds (*Ptilonorhynchus*, Kuhl), and the Mainots, since the *Pastor musicus* at once shows, in his opinion, the natural stations and affinities of all these birds.

Mr. Swainson finds the passage to the *Sturninæ*, or true Starlings, easy and natural, as he traces in the mainots many of the characters of the grakles united with those of the *Pastor* starlings. In the *Sturninæ* the bill is much more straight, and the under mandible considerably thickened at the base, where the commissure forms an abrupt angle. Mr. Swainson notices the great strength of the legs in these birds, indicating their walking propensities exerted in following the tracks of cattle in order to search after such insects as are disturbed by their grazing. He adverts to the association of crows and starlings in the same field, nearly in the same flock, and almost adopting the same habits, each bird representing the other in its own particular family; in both, he remarks, the lengthened and conic form of the bill is well adapted for searching after insects in the ground; both walk in the same stately manner, and both seem so attached to cattle and sheep as to rest upon their backs. The common starling may sometimes walk stately, but when we have observed it hunting assiduously for its insect food, the gait is more like a hurried run than a stately walk. But to return to Mr. Swainson; he remarks that the genus Pastor has the bill compressed, but in the European Starlings (*Sturnus*) that organ is more acute and depressed; the notch also, he adds, is so faint as to be nearly obsolete. In concluding his observations on this subfamily, he adverts to some of the foreign Pastors leading to *Gracula*, Cuv., as being furnished with naked wattles, and as appearing to be providentially created to destroy the devastating flights of locusts which so often appear on the plains of Southern Africa.

The same author makes the *Agelainæ*, or Maize-birds, succeed to the true starlings; and he thinks that the two subfamilies are so completely united by the *Sturnella collaris* (collared starling of South America), that but for the discovery of the genus *Oxystomus*, it would be difficult to say in which group *Sturnella* should be placed. Mr. Swainson observes that we now enter upon a group which he considers so truly natural, that his surprise is excited in no small degree by the confused notions of certain writers regarding their distinctions. To ignorance of the natural habits of these birds, or a disregard of that peculiarity of structure which would in some respects point out their habits, he attributes their being considered as part of the hang-nests (*Icteridæ*) by most writers, and their being actually united to them and the *Quiscalinæ* in the same genus by Wagl. r The fact however, in Mr. Swainson's opinion, seems to be that nature has distinctly separated the American orioles of Linnæus into three great groups, yet that she unites them so completely by insensible gradations, that unless the whole are analysed, their true distinctions will never be detected. As in the case of the boat-tails and hang-nests, the *Agelainæ* are, Mr. Swainson tells us, confined to America, and he is consequently enabled to say something of them from personal observation. 'Whenever,' says Mr. Swainson, 'during our travels through the wilds of Brazil, we reached the *corals*, or cattle enclosures, we were sure to meet with these birds; of which many species (in general very obscurely known) are found in all parts of that empire. The primary character therefore of the maize-birds is, that they are *terrestrial*, while those of the next family are *arboreal;* and both these peculiarities are rendered sufficiently apparent by external structure. In the maize-birds the feet, like those of the starlings, are strong and lengthened; and the elevation of the tarsi at once proclaims their habits. This structure is carried to its maximum in the Mexican *Agelaius longipes*, Sw., and in the North American *Agelaius icterocephalus*, Bonp. (Bonap. ?). There is still another characteristic of these birds: to enable them to retain a firm hold on the smooth stems of the maize and other grain upon which they feed, their claws are slender and acute, while the tail (always bent downward when the bird is in such an attitude) is frequently worn at its extremity. In the scansorial genus *Dolichonyx*, Sw., this habit is actually accompanied by the scansorial structure of the tail, the feathers of which are rigid and pointed. The most interesting genus of this group is the *Molothrus pecoris*, or cow-bunting of Wilson, the only bird, except the cuckoo, which deposits its eggs in the nests of other birds.' [MOLOTHRUS, where it is stated by mistake that Mr. Swainson has placed the form in the subfamily *Icterinæ*.]

The fifth and last division of the *Sturnidæ* consists, according to the arrangement of Mr. Swainson, of the *Icterinæ*, or *Hang-nests*, and he remarks that they are so intimately connected with it, that naturalists had not hitherto been aware of their true distinction. The group is strictly South American, gregarious, wary, and ingenious; building long purse-shaped nests, suspended from the slender branches of lofty trees: yet, says Mr Swainson in continuation, unlike all the preceding genera, these birds are never seen upon the ground, and though the legs are robust, they are short, with broad, strong, and fully curved claws. He finds the subordinate types well distinguished by slight but perfectly characteristic differences in the form of the bill, wings, and tail; the full perfection of the group being seen in *Icterus*, not, as it has been thought, in *Cassicus*, which, according to Mr. Swainson's views, is the rasorial type. *Buphaga* is excluded by the same author from the *Sturnidæ*, and placed among the *Certhiadæ*; and he passes from *Agelainæ* to *Fringillidæ*, and from *Fregilinæ* among the *Corvidæ* to *Buceridæ*, the circles touching each other at *Scaphidurinæ* and *Glaucopinæ*, as they appear in Mr. Swainson's *Synopsis*.

Sturnidæ. *Starlings*.

Family Character.—Size smaller than that of the *Corvidæ*. Stature less robust. Bill angulated at the base; the upper mandible entire. Lateral toes equal. (Sw.)

Subfam. *Sturninæ*.

Subfamily Character.—Bill in the form of a lengthened cone; longer than the head; the commissure with an acute angle at the base.

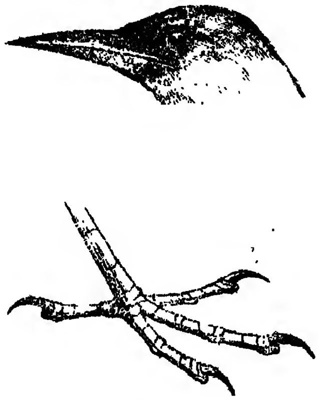
Genera.

Sturnus, Linn.—Bill depressed from the base as far as the tip, which is slightly inflexed, and obsoletely notched. Culmen convex and rounded. Wings lengthened, pointed; the first quill minute and spurious; the second and third longest. Tail short, divaricated. Feet moderate, terrestrial. The lateral toes equal; the middle toe as long as the tarsus; hinder toe shorter. The conirostral type. (Sw.)

Example, *Sturnus vulgaris, the common Starling*.

Pastor, Temm.—Bill depressed only at the base, compressed beyond; culmen slightly bent. Tip of the upper mandible deeply notched. Commissure distinctly angulated at the base. Nostrils large, feathered. Wings moderate in length, ample in breadth: first quill very minute;

the second nearly equal to the third. Tail short, broad, rounded. Feet very large and strong. Middle toe as long as the tarsus; hinder shorter; lateral toes equal. Claws somewhat slender, acute, but not much curved.



Head and foot of Starling.

Locality.—Warm latitudes of the Old World. The dentirostral type. (Sw.)

Example, *Pastor roseus*, the Rose-coloured Ouzel. Not unfrequently seen in Britain.

Gracula, Auct. [ROLLERS, vol. xx., p. 68.]

Acridotheres, Vieill.—General structure of *Pastor*; but the whole of the head entirely naked, and furnished with fleshy crests and wattles. Nostrils large, naked. Feet moderate. Tail even. Bill very wide at the base. The tenuirostral type. (Sw.) Example, *Acridotheres carunculatus*.

Oxystomus, Sw.—Bill much lengthened, longer than the head: the sides are compressed. Culmen flattened, nearly straight, and angulated on each side; the base advancing very far upon the head, and dividing the frontal feathers. Nostrils placed in a large depression towards the base of the bill. Wings very short and considerably rounded. Tail moderate, rounded; all the feathers, and the secondary quills, ending in setaceous points. Legs long and robust. Tarsus much longer than the middle toe; lateral toes unequal, the inner shortest. Pacific Islands. The scansorial type. (Sw.) Example. *Oxystomus carunculatus*.

Subfam. *Lamprotorninæ*. *Grakles*.

Subfamily Character.—Bill thrush-like, compressed: the culmen curved from the base. Lateral toes unequal.

Genera.

Ptilonorhynchus.—Size large. Bill short, very thick, convex above: both mandibles distinctly notched. Nostrils placed half-way between the gape and the tip, partly concealed by the short thick-set feathers of the front, which lie on the basal half of the bill. Wings rather short, rounded; the first and second quills graduated; the third shorter than the fourth and fifth, which are the longest. Tail moderate; the feathers broad, their tips truncated. Feet ambulating, large, and very strong. Middle toe and tarsus of equal length, hinder toe very strong, but much shorter; lateral toes unequal, the outer longest, and united to the middle as far as the first joint. Australia. (Sw.)

Example, *Ptilonorhynchus holosericeus*.

Lamprotornis, Temm. *Grakle.*—Bill thrush-like, compressed its whole length. Culmen curved from the base to the tip. Upper mandible notched. Commissure slightly curved. Nostrils midway between the tip and the gape, *naked, but with the frontal feathers reaching to their base.* Wings long, ample: the first quill spurious; the third, fourth, and fifth of equal length, and longest. Tail short, even, rounded, or (as in the rasorial type) considerably lengthened and cuneated. Feet very large and strong. Middle toe and tarsus equal; hinder strong, but much shorter; lateral toes unequal. (Sw.)

Example, *Lamprotornis ptilonorhynchus*. 'Birds of West Africa,' i. 140.

Subfam. *Scaphidurinæ*. *Boat-tails.*

Subfamily Character.—Bill of a very lengthened conic shape, entire, and compressed: the culmen slightly curved. Tail graduated, the sides reflected upwards, or boat-shaped. Feet strong. (Sw.)

Genera.

Astrapia (ante, p. 173).

Scaphidura, Sw.—Bill longer than the head, conic. Both mandibles equally thick. The base of the culmen broad, flattened, and advancing very far on the front of the head. Commissure angulated at the base, and sinuated on the sides. Nostrils basal, placed in a small triangular hollow on the sides; the membrane obsolete. Wings lengthened, pointed: the first quill longest. Tail moderate, graduated, boat-shaped. Feet strong. Middle toe and tarsus of equal length; hinder toe much shorter; inner toe hardly shorter than the outer. South America. (Sw.)

Example, *Scaphidura Barita*.

Quiscalus, Vieill.—Bill longer than the head, compressed. Both mandibles equally thick. Culmen slightly curved, and compressed from the base, where it simply divides the frontal feathers, without being dilated. Commissure considerably sinuated. Nostrils broad, naked; the aperture round. Wings moderate, somewhat pointed: the two first quills slightly shorter than the third and fourth, which are the longest. Tail rather lengthened, much graduated, boat-shaped; tips of the lateral feathers truncated. Feet large, strong. Middle toe and tarsus equal: hinder toe shorter; inner toe scarcely shorter than the outer. America. (Sw.) Example, *Quiscalus versicolor*.

Scolecophagus, Sw.—Bill shorter than the head, straight, slender; the margin inflexed, but not sinuated. Wings moderate, pointed; the first quill rather shorter than the second. Tail divaricated, flat, and slightly rounded. Legs lengthened, slender, formed for walking. Middle toe and tarsus of equal length; hinder toe shorter: lateral toes of equal length. Claws slender, acute, slightly curved. (Sw.)

Example, *Scolecophagus ferrugineus*.

Subfam. *Icterinæ*. *Hang-nests*.

Subfamily Character.—Bill completely conic, entire, rather shorter than the head, either straight or with both mandibles slightly bent. Feet formed for grasping. The claws thick, broad, and much curved. (Sw.)

Genera.

Cassicus, Daudin. *Cassicans.*—Bill rather longer than the head; the base thick, very convex, and enlarged into a broad oval plate, which advances very far on the front, and divides the frontal feathers. Nostrils oval, naked, basal, pierced in the solid substance of the bill, and close to the margin of the upper mandible. Commissure straight, but angulated at the base. Wings rather long; the first and second quills graduated. Tail graduated. Feet short, very strong. Hind toe and claw nearly as long as the tarsus. Tropical America. (Sw.)

Zanthornis (Xanthornus), Cuv.—Bill not longer than the head, generally shorter, perfectly straight; the culmen not dilated at the base, but simply dividing the frontal feathers. Wings moderate, pointed; the first three or four quills generally or nearly equal. Tail moderate, rounded. Feet moderate, but with the hinder toe manifestly longer than the tarsus; lateral toes unequal. America. (Sw.)

Example, *Xanthornus Baltimorii*.

Icterus, Cuv.—Bill somewhat lengthened, as long as the head, or longer: both mandibles slightly curved, and considerably attenuated. Nostrils basal, rather large, covered above by a membrane; the aperture lateral and oval. Wings moderate; the first and second quills rather shorter than the third. Tail somewhat lengthened, graduated. Feet moderate. Inner toe shorter than the outer; hinder toe shorter than the tarsus. Example, *Icterus castaneus*.

Chrysomus, Sw.—Bill resembling *Zanthornis* (Xanthornus must be meant); but the margin of both mandibles inflexed. Wings moderate; the first quill rather shorter than the second. Tail rounded. Feet formed for walking. Toes large, very long and slender; middle toe longer than the tarsus; lateral toes equal; hinder toe shorter than the tarsus. Claws long, very slender, and but slightly curved. (Sw.) Example, *Chrysomus icterocephalus*.

Subfam. *Aglainæ*. (Agelainæ?) *Maizers*.

Subfamily Character.—Bill short, thick, entire, completely conic, sometimes depressed, and rounded at the tip. Culmen rather broad, and flattened at the base. Legs long, slender, formed for walking.

Genera.

Dolichonyx, Sw.—Bill very short, finch-like, conic, entire, shorter than the head; the commissure sinuated. Wings pointed; the first and second quills longest and nearly equal. Tail slightly graduated, subscansorial; the tips acuminated, and somewhat rigid. Legs long, slender. Middle toe longer than the tarsus; lateral toes unequal, the

inner longest; hind toe of equal length with the tarsus. Claws long, very slender, and slightly curved. (Sw.)

Example, *Dolichonyx oryzivorus.* [BOB-O-LINK.]

Agelaius, Vieill. - Bill short, very conic, entire: the tips compressed: the culmen flattened towards the base; sides of the mandibles inflexed. Wings lengthened; the two first quills longest. Tail slightly rounded. Legs long, slender. Middle toe nearly as long as the tarsus. Claws long, very slender, and but slightly curved. America. (Sw.)

Example, *Agelaius pustulatus.*

Leistes, Vigors.- Bill lengthened, conic, very straight; the culmen depressed from the base to the tip, which is flattened. Wings moderate; the first quill rather shorter than the three next, which are the longest. Tail rounded. Legs large, strong. Middle toe longer than the tarsus: hinder toe shorter; lateral toes unequal, the outer one smaller than the inner: the hinder claw much stronger and more curved than the middle one. (Sw.) Example, *Leistes erythrocephalus.*

Molothrus, Sw. *Cowpen.* Example, *Molothrus pecoris.* [MOLOTHRUS.]

Sturnella, Vieillot.—Bill long, equal to the length of the head, conic, much depressed towards the tip, where it is broader than high: culmen dividing the frontal feathers, where it is depressed and flattened. Wings moderate; first quill rather shorter than the second. Tail short, rounded; the feathers rather narrow. Feet large, but slender. Tarsus longer than the middle toe. Lateral toes unequal, the outer shortest: hind toe not much shorter than the middle. Anterior claw small, and of equal size; hinder claw (typically) twice as long as the others. (Sw.)

Example, *Sturnella collaris.* (*Classification of Birds.*)

The family is immediately succeeded in Mr. Swainson's arrangement by the *Fringillidæ*, to which some of the species placed by him among the *Sturnidæ*, but by others among the Finches (*Dolichonyx*, for example), would seem rather to belong.

The Prince of Canino, in his *Birds of Europe and North America*, places the *Sturninæ* in his family *Corvidæ*, next to *Corvinæ* and arranges under the *Sturninæ* the genera *Acridotheres, Quiscalus, Scolecophagus, Sturnella, Icterus, Agelaius, Molothrus*, and *Dolichonyx.*

Mr. G. R. Gray (*Genera of Birds*) makes the *Sturnidæ*, which are immediately succeeded by the *Fringillidæ*, as they are in the Prince's method, follow the *Corvidæ.*

Mr. Gray divides the *Sturnidæ* into the following subfamilies:—

1. *Lamprotorninæ.*

Genera:—*Ptilonorhynchus*, Kuhl (*Pyrrhocorax*, Vieill.; *Kitta*, Kuhl); *Chlamydera*, Gould (*Ptilonorhynchus*, Jard.; *Calodera*, Gould); *Lamprotornis*, Temm. (*Turdus*, Lath.; *Lamprotornis*, Temm.); *Juida*, Less. (*Lamprocolius*, Sundev.; *Lamprotornis*, Temm.); *Megalopterus*, Smith; *Sturnia*, Less. (*Turdus*, Gm.; *Lamprotornis*, Sw.); *Aplonis*, Gould (*Turdus*, Lath.); *Cochoa*, Hodg.

2. *Buphaginæ.*

Genus, *Buphaga*, L.

3. *Sturninæ.*

Genera:—*Pastor*, Temm. (*Psaroides*, Vieill.; *Boscis*, Rehm.; *Turdus*, L.); *Acridotheres*, Vieill. (*Cossyphus*, Dum.; *Gracula*, Gm.); *Psarolophus*, Jard. and Selby (*Pastor*, Gould; *Oriolus*, Hodgs.); *Cutia*, Hodgs.; *Dilophus*, Vieill. (*Sturnus*, Lath.; *Pastor*, Temm.: *Acridotheres* (Vieill.), Swains.: *Gracula*, Gm., Cuv.): *Creadion*, Vieill. (*Sturnus*, Lath.; *Oxystomus*, Swains.: *Philesturnus*, J. Geoff.: *Philedon*, Cuv.; *Icterus*, Less.): *Sturnus*, L.; *Sturnella*, Vieill. (*Cassicus*, Daud.; *Alauda* et *Sturnus*, L.): *Amblyrhynchus*, Leach (*Oriolus*, Gm.; *Sturnella*, Vieill.; *Leistes*, Sw.).

4. *Quiscalinæ.*

Genera:—*Astrapia*, Vieill. (*Paradisea*, L.; *Lamprotornis*, Temm.); *Scolecophagus*, Sw. (*Gracula*, Wils.; *Quiscalus*, Bonap.; *Chalcophanes*, Wagl.); *Quiscalus*, Vieill. (*Icterus*, Temm.; *Quiscala*, Licht.; *Chalcophanes*, Wagl.; *Scaphidura*, Sw.); *Cassidix*, Less. (*Oriolus*, Gm.); *Scaphidura*, Sw. (*Gracula*, Gm.; *Quiscula*, Licht.; *Icterus*, Temm.; *Chalcophanes*, Wagl.).

5. *Icterinæ.*

Genera:—*Cassicus*, Briss. (*Icterus*, Temm.; *Xanthornus*, Pallas; *Psarocolius*, Wagl.; *Oriolus*, L.); *Cassiculus*, Swains. (*Icterus*, Bonap.; *Xanthornus*, Jard. and Selby); *Xanthornus*, Briss. (*Psarocolius*, Wagl.; *Yphantes* et *Pendulinus*, Vieill.; *Oriolus*, L.); *Icterus*, Briss. (*Oriolus*, L.; *Pendulinus*, Vieill.; *Psarocolius*, Wagl.); *Chrysomus*, Sw. (*Pendulinus*, Vieill.; *Oriolus*, L.).

6. *Agelainæ.*

Genera:—*Molothrus*, Swains. (*Emberiza*, Gm.; *Passerina*, Vieill.; *Psarocolius*, Wagl.; *Agelaius*, Swains.); *Leistes*, Vigors (*Agelaius*, Vieill.; *Psarocolius*, Wagl.; *Xanthornus*, Quoy et Gaim.; *Icterus*, Licht.); *Agelaius*, Vieill. (*Oriolus*, L.; *Sturnus*, Wils.; *Icterus*, Briss.; *Psarocolius*, Wagl.); *Dolichonyx*, Swains. (*Emberiza*, L.; *Passerina*, Vieill.; *Icterus* et *Emberizoides*, Bonap.; *Psarocolius*, Wagl.).

We have here given the views of some of the principal ornithologists relative to the family of starlings; and we think no one can peruse it without being struck with the uncertain state in which this department of natural history, in common with too many others, is, and the absolute necessity that exists for a reform of the nomenclature. How that reform is to be brought about is a problem of no small difficulty. A proposed plan for rendering the nomenclature of zoology uniform and permanent, which it is the intention of the proposers to submit at a future period to the consideration of the British Association for the Advancement of Science, has been sent to us, and, after a careful perusal of the scheme, we think that it rests upon sound principles; but the proposers must be prepared—indeed they seem to be so—for no light labour; nor will the measure ever be anything like complete till they can induce the zoologists of all other civilised parts of the world to go hand in hand with them. If they succeed in carrying out their measure to a full, satisfactory, and permanent conclusion, they will earn the merited praise of every one who is interested in the science. Previous to their submission of their plan to the British Association, the proposers are anxious to mature it as much as possible by obtaining the opinions of eminent zoologists in various countries: and they state that they will feel grateful for any remarks or criticisms with which they may be favoured, addressed to the care of Mr. Richard Taylor, Red Lion Court, Fleet Street, London. Several eminent zoologists have already formed themselves into a committee; and we have reason to believe that it is their intention to submit their plan to the next meeting of the Association at Manchester. They deserve the co-operation of all zoologists, and the encouragement of all men of science.

STURZ, HELFRICH PETER, born February 16th, 1740, at Darmstadt, was, although in a subordinate class of literature, a first-rate writer, and almost the first who distinguished himself by an elegant and graceful prose style in German, and by his playful humour. After filling the post of private secretary, first to Baron von Widmann at Munich, and next to the chancellor Von Eyben at Glückstadt, he went, in 1762, to Copenhagen, where he resided some time in a similar capacity with the minister Bernstorf, who obtained for him appointments of very considerable value. In 1768 he was made Danish 'Legationsrath,' and visited France and England in the suite of Christian VII. From this journey originated his 'Briefe eines Reisenden,' which contain many interesting details, and various anecdotes relative to the eminent literary characters and others to whom he had been introduced. At this period, while enjoying the present, he could look forward to still brighter prospects for the future; but the scene suddenly changed. Implicated in Struensee's fall, he was arrested in January, 1772, just as he was on the eve of being married, and although released within about four months, so great was the shock he experienced, that he never completely recovered from it, for it continued more or less to affect both his mind and his body during the rest of his life. His circumstances too were greatly changed by that event; and although he obtained an appointment which afforded him a sufficiency, it was in a small town in the duchy of Oldenburg, where he was completely removed from that polished and intellectual society which he had enjoyed in the capital. He had pined in this sort of banishment several years, when letters reached him from Copenhagen announcing the most flattering prospects, but such was the effect the unexpected intelligence had upon him, that he survived it only two or three days, being suddenly carried off by fever 12th November, 1779.

Besides the work above mentioned, and his 'Reminiscences of Bernstorf,' he wrote a number of literary papers on miscellaneous subjects, which he had begun to collect and publish just before his death.

STUTTGARD, the capital of the kingdom of Würtem-

berg, and the residence of the king, is situated almost in the centre of the kingdom, in 48° 45′ N. lat. and 9° 12′ E. long., 759 Paris feet above the level of the sea. It lies at the bottom of a valley, surrounded on three sides by mountains and hills, which are covered with vineyards and gardens. The valley is extremely fertile, and forms what the Germans call an English garden, extending to Kannstadt. The city consists of the old town, the suburb of Essling, the upper (or rich) suburb, and the new streets and suburbs built under the late King Frederick. These however have been all thrown into one, every mark of separation between them being removed. The old part of the city is ill built, the streets being narrow and irregular, and the houses, for the most part, of wood. The more modern parts have straight streets, intersecting each other at right angles, and contain many handsome buildings. The new royal palace, in particular, is a noble edifice, consisting of a centre and two wings; it has an extensive park, and in front of it is the spacious parade. The gardens and grounds of the palace are very fine, and extend to the new royal country-seat of Rosenstein, near Kannstadt. The palace contains a good collection of paintings and statues, and the windows command delightful views over the adjacent country. In the vicinity of the palace there are several public institutions. Among other buildings deserving notice (of which Stuttgard has, in proportion to its size, a great number) are, the Gymnasium Illustre, the building formerly the military academy, which resembles a palace, the old palace, the opera-house (one of the largest in Germany), the hotel of the department of foreign affairs (formerly the palace of the crown-prince), the royal mews, the palace of the estates of the kingdom, the archives, the new hospital, the three principal Protestant churches, the Roman Catholic chapel, the French Protestant church, and the three barracks, which are among the most considerable buildings in the city. There are numerous public and private collections of works of art, and several libraries; the public royal library contains 200,000 volumes, among which is a unique collection of 12,000 bibles, of 4000 different editions, in 68 languages. The king's private library of 30,000 volumes contains valuable old works and manuscripts, and a great variety of splendid modern publications. Stuttgard has a gymnasium, an academy of arts, a school of arts, a botanic garden, a veterinary school, a topographic-statistical society, a savings'-bank, a Bible society, and numerous schools, and other useful establishments for the poor, and charitable institutions of all kinds. The institution called Katharinenstift is a school for girls, founded by the grand-duchess of Oldenburg, sister of the emperor of Russia, who was in England with the emperor Alexander, and afterwards married the king of Würtemberg. She died in 1819. The population of Stuttgard is 35,000, with the garrison and strangers. There are manufactories of linen and woollen cloths, silk, cotton, gloves, carpets, shawls, &c., and the place is noted for its beautiful works in gold, silver, and bronze; excellent mathematical, philosophical, optical, and musical instruments; cabinet furniture, lackered ware, and carriages. The bark-trade is extremely flourishing.

The history of the city does not carry us back into remote antiquity. The name of Stuttgard first occurs in 1229. It appears however that it was a fortified town in 1286, when it was besieged for seven weeks by the emperor Rudolph I. In 1320 the sovereigns (then counts) of Würtemberg fixed their residence here, and since 1482 it has been the capital of all the possessions of the house of Würtemberg. Near Stuttgard is the beautiful royal country-seat 'The Solitude,' situated on a mountain.

(A. Fischer, *Das Königreich Würtemberg*, 1 vol., Stuttgard, 1838; J. D. G. Memminger, *Beschreibung von Würtemberg*; Hassel; Stein; Hörschelmann; Cannabich, &c.)

STYLA'RIA, Lamarck's name for *Nais proboscidea*, one of the Abranchous Setigerous Annelids of Cuvier.

STYLE. (Botany.) [STIGMA.]

STYLE, used for manner of writing, from the Latin *stylus*, the same word with the Greek στύλος, a 'pillar' or 'column:' στύλος probably contains the same element with ἵ-στη-μι, 'to place' or 'make erect,' and with the verb στύομαι. The Romans gave that name to an iron bodkin having a sharp point, with which they were accustomed to write by exaration, or scratching, on their wax-covered tablets or note-books; and from the instrument of writing, the term was transferred to the writing itself, and that too considered in reference not to the form of the characters (which would have been the more immediate transition), but to the mode of expression. Among the Romans however the term, in this figurative application of it, retained always considerably more of its antecedent meaning than it does with us. We say not only style of writing and style of speaking, but style of painting, style of architecture, style of dancing, style of dress, style of anything in which form or manner is conceived to be, in however slight a degree, expressive of taste or sentiment—if even this much of distinction still remains between what is called style and mere manner in the widest or loosest sense.

Style, in writing or speaking, may of course mean a bad style as well as a good style. Yet when the word stands alone, we always understand it in the latter sense—just as when we speak of expression in painting or in music we mean just or forcible expression. Thus Swift has said, 'Proper words in proper places make the true definition of a style.' This however is merely to tell us, what is sufficiently obvious, that the art of expressing thought by language consists in two things: first, the selection of words; second, their collocation or arrangement. That to constitute a good style, both this selection and this collocation must be proper, there can be no doubt; the only question is, what constitutes propriety as to such matters. Style has been sometimes considered as nothing more than the image or outward expression of thought, as its produce or creation in the same sense in which it may be said that the impression upon the wax is the creation of the seal; and it has hence been assumed that all that is necessary for the ensuring of a style of any degree of excellence is the possession of a corresponding power of thought. But a little reflection will satisfy us that this is an insufficient explanation. Of two men equal in powers of mind, and equally in possession of a subject, nothing is more common than that the one should be able to expound it much more clearly and effectively than the other. Language is an instrument the use of which must be learned like that of any other instrument. As a man may have a high capacity for music, and may have a perfect idea of a tune in his head, or may even be able to sing it, without being able to play it or any other on the violin, so a man may have the intellectual powers which fit him for excelling in oratory or poetry, without having the knowledge or command of language necessary to give them adequate effect. Style is rather the vehicle than the mere expression of thought; and the thought may be present where the vehicle is wanting. To some extent also it may be said to be the dress of thought, or that which ornaments and sets off thought, not only by the added charms of sound, but by other powers which are inherent in words, and of which unexpressed thought knows nothing. As there are 'thoughts that breathe,' so there are 'words that burn'—that by their associations excite impressions of the grand, the pathetic, or the humorous, whether they are addressed to the ear or merely to the eye. And great effects are also to be achieved by the arrangement of words, not only in the production of melody and cadence, but in a higher kind of gratification or excitement—as by the luminous disposition of all the parts of the sentence, by the presentment of every term at the place best fitted to bring out its whole import, by all the resources of what the grammarians call inversion, ellipsis, and other figures of speech; which indeed, wherever they are properly used, are no deviations from natural syntax at all, but, on the contrary, the most natural forms that can be employed. For, while writing is an art, it is nevertheless most true that, like all the other arts the purpose of which is to give expression to mind, the guiding and controlling principle of its exercise, its life and being, as we may say, must ever be as exact and sympathetic a conformity as possible to the thoughts or emotions of the writer. Whatever more style is than the mere expression of thought, that much it must be at the least. A powerful thinker may not always be a powerful writer, but no man can be a powerful writer who is not a powerful thinker. Even the humblest quality of style, mere perspicuity, cannot be attained without a corresponding degree of clearness of thought. We sometimes meet with a perspicuity which is little more than grammatical, and hardly belongs to style at all; but even that implies distinct conceptions so far as they go—a limpid stream of thought, however little depth or spaciousness of intellect. And as for all higher attributes, it is manifest that they cannot be found in the style, if they do not exist in the mind of the writer. The only fountains

from which a man's words can derive the animation of true passion, or poetry, or wit, must be his own head and heart.

The lowest kind of writing that deserves the name of a style at all (unless it is to be called a bad style) ought, as we have observed, to be perfectly perspicuous, that is to say, readily and completely intelligible in so far as the understanding of it depends merely upon a knowledge of the language. The subject may be a difficult one, but that is only a reason for more pains being bestowed to make the style clear and easy, by a lucid arrangement and the avoidance of all ambiguities of expression. But although this rule may be justly insisted upon where nothing beyond such perspicuity is desirable, it will not bear to be so rigidly enforced in regard to the higher kinds of style. Here some sacrifice even of perspicuity is at times to be submitted to, for the sake of appropriate effects which could not be otherwise attained. Æschylus, no doubt, might have made his choruses, Pindar his odes, Tacitus his historic pictures, more easily comprehensible, better fitted for the use of such readers as would always run while they read, by greater diffuseness and dilution of style; but much more certainly would have been lost than gained by the attempt. Facility of being understood is a valuable quality in a style which has no other attractions; but it has been greatly overrated by the rapturous way in which the grammarians have been accustomed to speak of it. What is to be desired in the highest kinds of writing, as in the highest creations of all the fine arts, is not perfect comprehensibility at a glance, but rather that fulness and profundity of meaning which can never be wholly comprehended, but supplies inexhaustibly something new to be seen and felt every time we return to the work.

In every cultivated language however, the progress of style is decidedly towards more and more of first-sight intelligibility, in so far as that depends upon precision of phrase, and the use of words in certain limited meanings. This has been remarkably the history of the English language, at least for the last two hundred or two hundred and fifty years, during which we have been fixing both our grammatical forms and our rules of syntax to an extent that would surprise most persons if the evidences of it were stated in detail. Whether all that has been done in this way has really improved the language,—whether it has been thereby rendered more expressive, more flexible, more fitted for the various ends which a language ought to subserve, may perhaps be questioned. The gain in point of precision may possibly be more than balanced by the loss both in ease and in variety of style. We will instance one of the modern regulations about which the grammarians are wont to make a very great cry, the asserted necessity of always taking care that the reference of the personal or relative pronoun should be to the last-mentioned substantive of the same gender and number. Now, in the first place, this rule never is nor has been observed in the practice of any writer as it is laid down in the grammars: the reference of the pronoun is always not to the most proximate, but to the most prominent, of the antecedent substantives—to the one which the course of the sentence or statement has placed uppermost in the reader's mind; that is the actual, as it is the natural reference, and it would be absurd that the pronoun should be used upon any narrower principle. But in former times even that principle was by no means rigidly adhered to. If we turn, for example, to the 'Fairy Queen,' we find Spenser, certainly one of the greatest masters of language that ever wrote, and who has applied all the resources of his own English at once with the most consummate skill and the most wonderful effect, making his *hes*, and *shes*, and *its*, in every stanza, perform all sorts of services, and refer to almost any preceding substantive he pleases, wherever they may be placed. Nor is this licentiousness attended with any practical inconvenience. It may be a little offensive at first to our unaccustomed eyes or ears, but this soon wears off; the meaning of the passage is usually as obvious as if the modern rule were ever so carefully attended to, while the advantage which the disregard of it gives in point of spirit and freedom to the composition is far from inconsiderable.

In another respect however English prose eloquence has undergone a change of character in an opposite direction, by the greater infusion which it has received of a colloquial tone and phraseology within the last century and a half. Till towards the close of the seventeenth century the language of books, except in the comic drama and other light compositions of a kindred character, generally preserved a formality of gait and manner which distinguished it nearly as much from living conversation as the critics have held that the language of verse should be distinguished from that of prose. Among the most eminent of the writers who first broke through this species of restraint were Cowley, in his Essays; Dryden, in his prefaces and other prose discourses; Sir William Temple, and the third earl of Shaftesbury. The example set by them was followed by Swift, Addison, Steele, and their associates and imitators, till in the earlier part of the last century the colloquial ease and liveliness, which had thus become fashionable, threatened to degenerate into a slovenliness, or shambling fluency, alike without either elegance or precision. It must be admitted, that of all the writers of the second quarter of the eighteenth century, Lord Bolingbroke, whatever opinion may be entertained of his depth of thought or weight of matter, wrote the best style, at once the most flexible and idiomatic, and the purest, most refined, and most musical. But probably the writer who on the whole did most to restore measure and emphasis to our prose style was Johnson: his manner has not been much copied in all his peculiarities or in its entire character, but yet more or less of its influence may be detected in the style of nearly every one of the more remarkable writers who have subsequently appeared among us, including even such diversities as the sonorous inanity of Macpherson's 'Ossian,' the epigrammatic point and terseness of Junius, and the brilliant falsetto of Gibbon. At the same time however examples of altogether a different character were also producing their effects; and the rude vigour of Warburton, the naïveté of Sterne and Goldsmith, and, above all, the rapidity, variety, and imaginative splendour of Burke, have all operated powerfully in forming the greatest of our later writers. Finally, with all these influences have mingled and co-operated two others which have also been impulsive and generative to a considerable, though not both to the same extent:—on the one hand, the revived study of our old Elizabethan literature; on the other, the new life and spirit that has been put into literature, as into all things else, by the political and social convulsions of the last fifty years. These two influences, though thus apparently opposite in origin, have proved rather mutually assistant than contradictory.

Purity of style is more intimately connected with many apparently higher things than is commonly supposed. Remarking on 'the power and value of words, and the duty as well as advantage of using them appropriately,' Coleridge says (in a note to his work 'On the Constitution of the Church and State,' 1830, p. 19), 'Many years ago, in conversing with a friend, I expressed my belief that in no instance had the false use of a word become current without some practical ill consequence, of far greater moment than would, *primo aspectu*, have been thought possible. That friend, very lately referring to this remark, assured me that not a month had passed since then without some instance in proof of its truth having occurred in his own experience; and added, with a smile, that he had more than once amused himself with the thought of a verbarian attorney-general, authorised to bring informations ex-officio against the writer or editor of any work in extensive circulation, who, after due notice issued, should persevere in misusing a word.' When it is considered indeed what the wrong use of a word in most cases springs from and implies, the mischief it is apt to occasion is easily understood. It is produced by a confusion of thought, which is propagated wherever the vicious mode of expression prevails, and which, besides the injury done in the particular case, helps generally to impair the habit and the faculty of clear and correct thinking. Yet words, for obvious reasons, have a strong tendency to shift their signification; if a language were to be merely spoken, and not written, this would be constantly taking place to a very great extent; the only thing that can check it, that can furnish a practically available standard of the language, is the employment of it in writing. Originally indeed the principles upon which it is written must be taken from its spoken form—from the *usus et norma loquendi*; but afterwards commonly the spoken language both will be and ought to be rather regulated and controlled by the written language. If it should continue to be otherwise, the language would not improve, but would degenerate towards barbarism; for there could be no progress in any other direction, in this or in anything else, where

the comparative slovenliness and incorrectness of extemporaneous precipitation were allowed to carry it over the best efforts of deliberation and care. There is always danger however of something of this happening wherever extemporaneous oratory is much in demand; and where the practice of public speech-making prevails to a great extent among the imperfectly educated classes, the case is of course so much the worse. There is reason to fear that such an influence is acting, along with other causes [AMERICANISMS], to seduce the more ambitious writers of English America into an inflated, big-worded, loud sounding style, which is about as offensive to good taste as the noisy exaggerated eloquence of a person half drunk always is to a sober man. The speechifying or preaching style seems to threaten to become the only style even for written composition in the United States, and its standard the violent vociferation and empty rumble of the newspapers.

STYLE, OLD AND NEW. By the Old Style is meant the mode of reckoning time anterior to the Gregorian reformation of the calendar; and by the New Style, that adopted since. The adoption of the reformation at different times by different countries, renders it necessary to remember the difference of their reckonings, as follows.

The reformation took place in 1582; from thence to the end of February, 1700, new style is *ten* days in advance of old style: thus January 1 (O. S.) is January 11 (N. S.), and so on.

From and after March 1, 1700, to the end of February, 1800, new style is eleven days in advance of old style: thus January 1 (O. S.) is January 12 (N. S.).

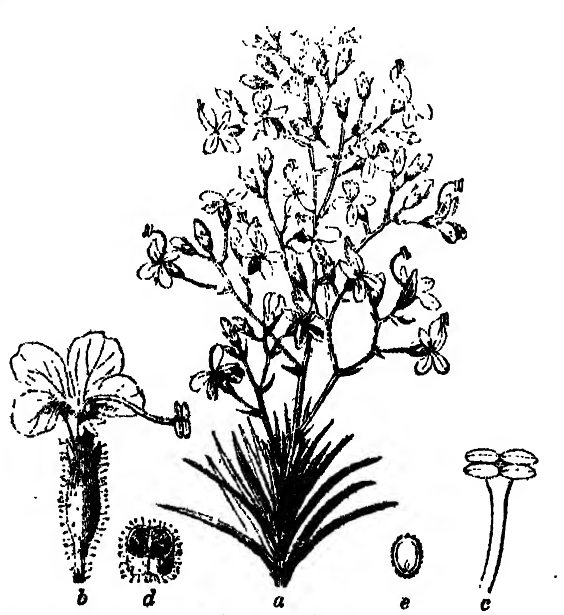
The new style was adopted in England by 24 Geo. II. (1751), which enacted, 1, That the year 1752 should begin on the 1st of January instead of the 25th of March, which was then the *legal* commencement. 2, That the 3rd day of September, 1752, should be called the 14th, or that the days from the 3rd to the 13th inclusive should have no nominal existence. Accordingly, the year 1751 had no January, February, nor March up to the 24th inclusive; and September wanted eleven complete days.

According to Sir Harris Nicolas, the new style was adopted as follows: by Denmark, France, Holland, and most of the Low Countries (some towns excepted), most of Italy, Lorrain, Portugal, and Spain, in 1582; by German and Swiss Catholics in 1584; by Poland in 1586; by Hungary in 1587; by German and Swiss Protestants, and the remaining parts of Holland, &c. in 1700; by Tuscany in 1749 or 1751; and by Sweden in 1753. It is not yet adopted in Russia.

It was at one time sometimes the mode to express the date in both styles. We have an old letter written from France to Holland in 1619, as we should now call it, the date of which is Février $\frac{18}{28}$, 161$\frac{8}{9}$. [PERIODS OF REVOLUTION.]

STYLES OF ARCHITECTURE. All the principal styles have been spoken of under the heads of CIVIL ARCHITECTURE—*Egyptian, Gothic, Hindu, Italian, Lombardic, Mexican, Moorish, Norman, Roman*; and to them may here be added some subordinate styles, which are to be considered rather as peculiar and temporary modes, than distinct, independent, and established styles. Such are those known by the appellations of Burgundian, Flamboyant, Cinque-cento, and Elizabethan. Of these the two first mentioned are peculiar to France; and the *Burgundian* may be considered as corresponding with our own Tudor, since it exhibits, with many points of difference, many also of resemblance, and the same general character as to enrichment, and the adoption of very flattened arches, or else horizontal lintels, for the openings of windows. Château Fontaine le Henri and several other examples of this style may be seen in Pugin's 'Antiquities of Normandy.' *Flamboyant* is a term that has recently been applied to that species of French Gothic whose tracery is entirely composed of flowing curves, forming not a perfectly symmetrical pattern. The name has been bestowed from the fancied resemblance to the waving outline of *flames*. The portals of Abbeville, Beauvais, and St. Maclou at Rouen are fine specimens of this style. *Cinque cento*, otherwise sometimes called the *Renaissance* style, is that which arose on the first attempt to revive and apply the classical orders without any regard to their original character. If Roman architecture departs very widely from the principles of that of Greece, the Cinque-cento departs quite as much, and sometimes still more so, from those of the Roman. It is essentially *microstyle* in composition, the orders being treated as diminutive decorative features, not only intermixed with, but almost overwhelmed by others of very grotesque and incongruous design. Still the style possesses historical interest; and although devoid of beauty, is, in many instances, exceedingly rich and eminently picturesque. It was that which prevailed in France in the time of Francis I., and has lately been much affected and brought into vogue again in that country for purposes of interior decoration. Among others, Heidelberg Castle is a noted and splendid example of this style in Germany. What is called *Elizabethan* may be considered the English Cinque-cento or Renaissance—a style in itself full of barbarisms and extravagances, yet frequently rendered imposing by the magnitude of the structures in which it was displayed, and by that profusion of fantastic ornaments which recommends it to the taste of many even at the present day.

STYLIDIA'CEÆ, a natural order of plants belonging to the epigynous group of monopetalous Exogens. They are herbaceous plants, or under-shrubs, with aqueous juices, sometimes having hairs, which are simple, acute, or capitate; the stem and branches are round, or sometimes they have a scape. The leaves are entire, without stipules, mostly scattered, sometimes whorled, the radical ones clustered in the species which possess a scape. The flowers are solitary, or arranged in spikes, racemes, or corymbs, mostly terminal; the pedicels have three bracts. The tube of the calyx is attached to the ovary; the limb is 2-6-parted, bilabiate, or regular and persistent. The corolla is monopetalous, irregular, 5- or 6-cleft, imbricated in æstivation, and late in falling off. There are two stamens, the filaments of which are united with the style, the whole forming a single elongated column; the anthers are 1- or 2-celled; when the latter, they lie over the stigma; the pollen is globose, simple, sometimes angular. The ovary is 2-celled, or sometimes 1-celled from a contraction of the dissepiment, many-seeded, with a single gland in front, or two opposite ones; the style is one with the filaments, and the stigma, which is simple or bifid, is enclosed and hidden by the anthers. The fruit is a capsule, with two valves and two cells: the seeds are indefinite, small, erect, sometimes stalked; the embryo is minute, and enclosed within a fleshy somewhat oily albumen. This curious order of plants is allied to Campanulaceæ and Goodeniaceæ, but the peculiar union of its filaments and style into a single column distinguishes it at once. This column possesses a considerable degree of irritability. [STYLIDIUM.] There are only two genera of this order known besides Stylidium. They are chiefly found in New Holland, but species have been discovered in



Stylidium laricifolium.

a, cutting showing corymbose flowers and leaves; *b*, flower showing irregular corolla, tubular calyx, and capitate hairs; *c*, filaments and style, forming a single column, with anthers covering stigma; *d*, 2-celled ovary; *e*, section of seed with minute embryo.

the Himalaya, Ceylon, and the South Sea Islands. Their properties are unknown.

STYLI'DIUM (a diminution of *stylus*, 'a column'), the name of a genus of plants, the type of the natural order Stylidiaceæ. The essential characters of this genus are: calyx 2-lipped; corolla irregular, 5-parted, form of the segments equal, the fifth smaller, forming a labellum, which is deflected; column consisting of filaments and style, reflexed, with a double curve; anthers with two lobes widely separated; stigma obtuse, undivided; capsule bilocular, with the dissepiment sometimes superiorly incomplete. This is chiefly a New Holland genus of plants, and is remarkable for its gynandrous structure, and for the irritability of the column formed by the union of filaments and style. Irritability is seen in many genera allied to this, as in the indusium of Goodenia. The part which exhibits movement on being excited is the curved column, and the irritability is confined to a small portion only of the column near its base. In the natural state the column projects from beyond the flower, and hangs down over the smaller petal or labellum, and the irritable part of it is in contact with the labellum. The movement of the column consists in raising itself from this deflected position to that of perfect uprightness. In the bud, the column does not possess this power, but as the anthers develop, this property of the column increases, and is at its greatest intensity at the time of the dehiscence of the anthers, and entirely ceases when the impregnation of the ovules has taken place. During this process the anthers also undergo a change; previous to dehiscence, they entirely cover the stigma, but after this process has taken place, the stigma is fully exposed, and remains so. The irritability is then developed with the anther: it is at its greatest height whilst the anther is performing its function, and ceases with the function of that organ. The movement of the column is produced by external stimulants or the application of a solid body , Exposure to heat will erect the column, and its withdrawal will cause it to return to its natural position. After returning to this state, it requires ten or fifteen minutes' rest before it will again exhibit irritability. When elevated, the column cannot be made to return by force to its bent position. When the movement takes place naturally, it is slow and regular, and when under the influence of artificial excitants, it occurs suddenly and by jerks. The final cause of these movements is evidently connected with impregnation, and it seems that the pollen is conveyed to the stigma whilst the column is upright, which could not be the case whilst it was dependent.

The species of this genus described by Mr. Brown, in his 'Prodromus Floræ Novæ Hollandiæ,' are forty-five in number; besides these there are two or three natives of the East Indies.

STY'LIFER, or STILIFER, Mr. Broderip's name for a new family of PECTINIBRANCHIATA, characterised by him from a shell with the soft parts attached, among other specimens brought home by Mr. Hugh Cuming.

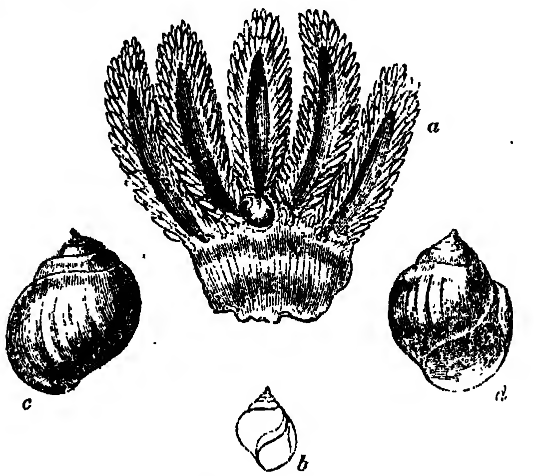
Generic Character.—Shell hyaline, turbinated, the apex of the spire mucronate. The aperture subovate, acuminated above. The external lip acute and sinuated.

Animal.—The mantle thick, fleshy, and cup-shaped, covering the last whorls of the shell. The proboscis very long and retractile. The tentacles round, thick, subacuminate, and situate at the base of the proboscis. Eyes very small, sessile at the base of the tentacles. Stem of the branchia solitary. Animal marine, penetrating into the integument of the star-fish.

Example, *Stylifer Astericola*, Brod.

Mr. Broderip states that the arrival of this species with the soft parts had afforded data for a generic character, indicating a distinct family among the *Pectinibranchiata*, the form of whose mantle differs from any other genus of that order. This mantle, which is of a green hue, is thick, fleshy, and cup-shaped, with a small aperture at its base, and a free posterior margin, enveloping the soft parts and the last volutions of the shell, which has thus somewhat the appearance of a small acorn set in its cup. On the ventral aspect of the mantle is the rudiment of a foot, and from the small basal aperture a retractile proboscis (which, when exserted, is as long as the whole animal) is protruded. At the base of the proboscis are two thick, round, somewhat pointed tentacula; and at the base of them are the eyes, or rather, ocular specks without pedicles. The branchia is placed on a single stem. At the base of the proboscis is a spherical muscular stomach, and the intestine ascends into the spire of the shell, where it becomes attached to the liver, which in *S. Astericola* is of an orange colour.

Mr. Cuming found this elegant parasite burrowed in different parts of the rays of the oral disc of *Asterias solaris*. It was almost hidden from sight, so deeply does the animal penetrate into the substance of the star-fish, in which it makes a comfortable cyst for itself, and wherein it most probably turns by the aid of its rudimentary foot. All the specimens infested with these testaceous mollusks appeared to be in the best health, though there is reason to believe that they feed upon the juices of the star-fish. Mr. Broderip observes that Stylifer (with that instinct of self-preservation which is imparted to all parasites whose existence depends upon that of their nidus) appears, like the larvæ of the ichneumon tribes among insects, to avoid the vital parts; for in no instance did Mr. Cuming find it imbedded anywhere save in the rays, though some of the individuals had penetrated at their base, and very near the disc. When extracted, the older shells have the appearance of a milky-clouded glass bubble: the younger shells Mr. Broderip found of an unclouded transparency.



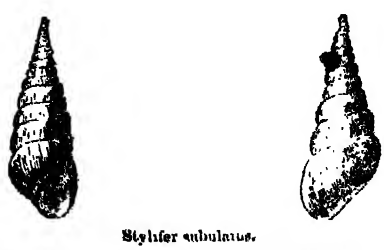
Stylifer Astericola. (Sowerby's *Genera*.)

a, a portion of *Asterias solaris*, showing *S. Astericola* in its cyst; *b*, a specimen of the shell; *c*, *d*, views of the upper and under side of the shell, magnified.

Mr. Broderip remarks that Dr. Turton, in the second volume of the *Zoological Journal*, p. 357, pl. 13, describes and figures a shell under the name of *Phasianella stylifera*, adding that he found a dozen attached to the species of *Echinus esculentus* dredged up in Torbay. Mr. Broderip observes that it is clear that Dr. Turton's shell is not a *Phasianella*, for it is described as having no operculum, and the similarity of the shell leaves no doubt, when joined to the parasitic habits of the animals, that it is one of the congeners of *Stylifer Astericola*. Mr. Broderip therefore names Dr. Turton's specimen *Stylifer Turtoni*.

Stylifer Turtoni.
Natural size and magnified. (*Zool. Journ.*)

Mr. G. B. Sowerby furnished Mr. Broderip with a third species, which, though its habits were unknown to the latter, he considers to be referrible to this genus, and he



Stylifer subulatus.
Natural size and magnified. (Sowerby's *Genera*.)

names it *Stylifer subulatus*; it is so beautifully transparent, that in fine specimens the columella can be as distinctly seen as if there were no intervening medium; and its long apex, which consists of many close-set whorls, is generally out of the perpendicular. (Broderip, in Sowerby's *Genera of Recent and Fossil Shells*, No. xxxviii.)

The characters of the species described by Mr. Broderip will be found in the *Proceedings of the Zoological Society of London* for 1832; and in Th. Müller's *Synopsis Testaceorum*, Berlin, 1836.

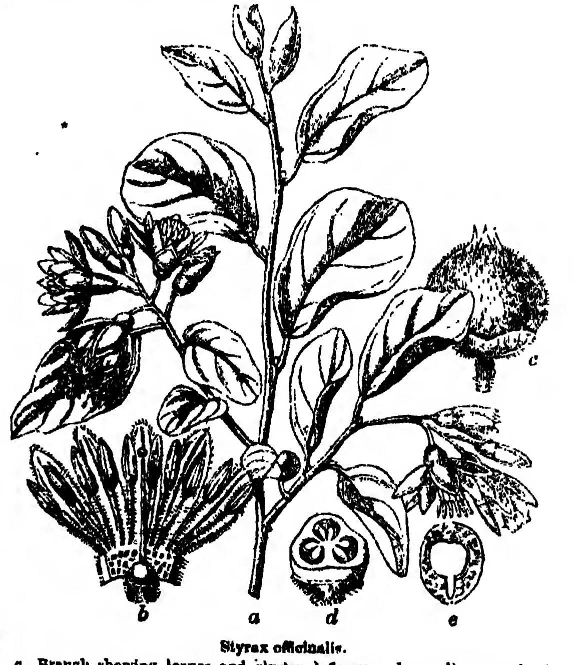
STYLOBATE. In its general meaning this term signifies any sort of basement upon which columns are placed to raise them above the level of the ground or floor; but in its technical meaning it is applied only to a continuous unbroken pedestal, upon which an entire range of columns stand—in contradistinction from *pedestals*, which are merely detached fragments of a stylobate placed beneath each column. So far were the Greeks from considering the stylobate an integral part of an order, that they very rarely employed it, but placed their columns immediately upon the floor of the elevated platform of the gradini, or deep steps, which served as the basement of the temple, and which were generally continued on every side. It was only in particular cases, such as where steps were confined to one end or the front of a building, that, whether columns were continued along its flanks or not, there was of necessity a basement added to those side elevations, equal in height to the ascent of the steps, or the difference of level between the ground and the pavement of the portico: which basement was treated as a distinct pedestal to the whole building. The height of such pedestal therefore varied according to circumstances, and was not strictly regulated by that of the order. Generally indeed it was low in proportion to it, but in the caryatic portico of the Erechtheium at Athens (copied at St. Pancras church, London) we have an example of a very lofty stylobate, its height being nearly equal to that of the figures themselves or the columns of that anthropostyle order. The Romans, on the contrary, broke up their stylobates into distinct blocks or pedestals placed beneath each column; and most followers of that or the Italian school have considered pedestals of that kind to be almost essential to an entire order, and have laid down proportions accordingly, which are in themselves exceedingly faulty, being much too high. At the best, columns upon detached pedestals always look as if placed upon stilts, and where such pedestals are as high as they are sometimes made—one-third, or even more, of the column itself—the columns seem to stand very insecurely, and the effect is very much like that of a round column immediately placed upon a dwarf square one. Another evil resulting from such practice is that the order itself, or columns and entablature, loses much of the importance, and the entablature ceases to be in proportion to the united heights of the column and additional shaft or subcolumn beneath it and in continuation of it. Unless absolutely indispensable, or where there must be some balustrading or parapet between columns, for the sake of security, and then they should be no higher than what convenience requires, pedestals should be avoided altogether. A stylobate, on the contrary, may be so employed as to give additional dignity to an edifice, without detracting from or interfering with the order itself, since it gives the whole structure an appearance of solidity in its lower part. The portico of the National Gallery owes much of its effect to the circumstance of its being elevated upon a solid unbroken stylobate, which is however too plain in itself to accord with the order, and even looks poor and unfinished, from the want of a suitable socle and base mouldings.

STYLO'CERUS. [DEER, vol. viii., p. 362.]

STYPTICS (from στυπτικός, 'astringent'), agents which check the flow, generally of blood, from a relaxed or ruptured vessel. They are a kind of astringent, and the principle of their mode of action has been already detailed. [ASTRINGENTS.] The only point requiring notice here is to enforce the necessity of their prompt employment, as the natural disposition of the blood to coagulate becomes less and less as it continues to flow, till fainting be induced, and a cessation of the current results, after much injury is done to the system. The bleeding may be spontaneous, as is frequently the case with young persons, from whose nose blood frequently flows, even when perfectly quiet, but still more frequently when running or lifting some heavy weight, or it may be the consequence of a wound, such as a leech-bite, or of the extraction of a tooth, or caused by some cutting instrument. Those astringents are alone entitled to be called styptics which can be applied directly to the bleeding orifice; and of these some act chemically, others vitally, and others merely mechanically. Of chemical styptics, a saturated solution of alum, or sulphate of zinc, or creasote, are the best. Strong acetic acid acts both chemically and vitally. When blood continues to ooze from the socket of a tooth, it is a useful plan to plug it with a sponge-tent, which, as it expands, quite fills up the socket, and restrains the hæmorrhage.

STYRA'CEÆ, a small natural order of plants, placed by Lindley in his polycarpous group of monopetalous Exogens. The species are trees or shrubs, with alternate leaves without stipules, usually turning yellow in drying. The flowers are axillary, and are either solitary or clustered with membranaceous bracts. The calyx is persistent, and has five divisions; corolla with divisions, frequently differing from the calyx, and with imbricated æstivation; stamens varying in number, arising from the tube of the corolla, with 2-celled anthers; ovary 3-5-celled, with few ovules, a simple style, and capitate stigma; fruit a drupe; seeds solitary, with the embryo lying in the midst of albumen. This order is nearly allied to Ericaceæ, from which it differs in habit, its definite seeds, and its frequently inferior ovary. It differs from Ebenaceæ in its stamens being perigynous, in the insertion of the ovules, and its simple style. It is however an order on which there are many different opinions, some referring all its genera to Ebenaceæ, whilst others separate from it the genera Symplocos and Halesia as types of distinct orders.

The species are found in the temperate and tropical parts of North and South America, and also in Nepaul and China. This order is chiefly remarkable, in an economical point of view, for furnishing the Storax and Benzoin of commerce, which contain a peculiar acid called the benzoic. Some of the species are used for dyeing yellow, and a species of Alstonia is employed as a substitute for tea. The various species of Halesia are the snow-drop trees of Carolina.



Styrax officinalis.

a, Branch showing leaves and clustered flowers; *b*, corolla opened with perigynous stamens and pistil; *c*, fruit covered with tomentum; *d*, transverse section of ovary, showing 3 cells; *e*, section of seed, showing embryo in the midst of albumen.

STYRAX (from στύραξ), the name of a genus of plants forming the type of the natural order Styraceæ. It has a persistent campanulate 5-toothed calyx; monopetalous deeply 3-7-cleft corolla; 10 stamens monadelphous at the base, with linear 2-celled anthers; superior ovary with indefinite ovules, with simple style and 3-lobed stigma; fruit a dry drupe; seed with a double testa, inverted embryo, and fleshy albumen. The species are elegant trees and shrubs, mostly covered with hairs having a stellate form, with entire leaves and white or cream-coloured racemose flowers. They are principally natives of America and Asia; one is found in Europe and one in Africa.

Styrax officinalis, official Storax: leaves ovate, downy beneath, shining above; racemes 5-6-flowered, simple, shorter than the leaves. It is a native of Syria, Italy, and most parts of the Levant. It is common all over Greece and the Peloponnesus, where Dr. Sibthorp found it retaining almost the same designation as that given it by Theophrastus and Dioscorides, the modern name being *στουρακι*. It was first cultivated in England by Gerarde, but is still a rare plant in this country. One of the finest specimens is in the Botanic Garden at Chelsea, and is annually covered in May and June with a profusion of rich blossoms. This is the species which yields the Storax which is admitted into the Materia Medica of the London Pharmacopœia. [STYRAX.] There is however another Storax known in commerce, with which this must not be confounded, and which is the produce of the *Liquidambar styraciflua*, a plant belonging to the natural order Balsamaceæ.

S. Benzoin, Benjamin Storax, or Gum-benjamin tree: leaves ovate-oblong, pointed, glabrous above, downy beneath; racemes compound, almost the length of the leaves. It is a native of Sumatra and Java. It is the plant which produces the gum Benzoin or Benjamin of commerce, and which, as well as Storax, is used in medicine. [BENZOIN.] The great consumption however of these resins is not as medicines, but in their use as incense in the worship of the Roman Catholics and Mohammedans. Though older botanists, as Garcias, Grim, and others, were acquainted with the tree that yielded Benzoin, Ray confounded it with the genus Laurus, and Linnæus with the genera Croton and Terminalia. Dryander gave a correct account of the plant in 1787, and referred it to its present position.

S. grandifolius, large-leaved Styrax: leaves broad, obovate, pointed, slightly serrated, green above, downy beneath; lower peduncles 1-flowered, solitary, axillary. A native of North America, in woods and on the banks of rivers from Virginia to Georgia. It is a handsome shrub, bearing white flowers, opening them in June and August.

S. lævigatus and *S. pulverulentus* are North American species, and are natives of the woods of the Carolinas and Virginia.

Several other species are described from South America, mostly from Brazil.

The hardy species of Styrax are well adapted for shrubberies, on account of their foliage and handsome flowers. They may be propagated by seeds sown in pots of light soil, and exposed to warmth, but the best mode is by layers, which should be put down in autumn or spring.

STYRAX OFFICINA'LIS is the source of the officinal storax, though an article is occasionally vended under this name, which is obtained from the Liquidamber styraciflua, and perhaps other species of Liquidamber. Of genuine storax there are several varieties, and of those known to the ancients many are now altogether unascertainable, while of those mentioned by even recent writers several are very rare, and only objects of curiosity, not of commercial importance. The tree grows in Greece and Asia Minor, and is cultivated in the south of France, in which last no resin exudes, except occasionally, after very warm summers. Asiatic Turkey supplies whatever is met with in commerce. It is procured by incisions in the bark, or perhaps from the punctures of insects. What flows from these openings is a liquid resinous substance, which concretes into small tears, about the size of peas; these, aggregated into masses, constitute the *styrax albus*, which is of extreme rarity. Another form is that called *amygdaloides*, also of great rarity and extravagant price. It is sometimes termed *calamita vera*. The commercial article is of various degrees of purity and excellence. One kind is called *storax calamita vulgaris*, or *Scobs storacina*. This always contains more or less sawdust, mixed with variable quantities of resin. It is generally in large round cakes, of a brown colour, verging to red or black, with fragrant odour, brittle, and friable, but softens in the mouth, and has a bitter taste. It burns with a light flame. It is considered to be an artificial compound, prepared chiefly in Venice and Trieste. According to the analysis of Reinsch, it contains—volatile oil, a trace only; resin, from 32 to 53 per cent. in different specimens; benzoic acid, from 1 to 2 per cent.; gum, 7 to 14; woody fibre, 20 to 27; ammonia, an inappreciable quantity.

Storax is stimulating in a degree dependent on its purity. For medical purposes it is directed to be purified by solution in alcohol, straining, and afterwards distilling off the spirit. The residuum is then used in a few preparations, such as tinctures and pills. It formerly entered into a multitude of compounds, but it has been greatly discarded, from the extensive adulterations practised with it, and it might be altogether supplanted by benzoin. It is much used to form pastilles, and for fumigations. The bark is called *cortex Thymiamatis*, or *cortex thuris*, from which, by boiling, *liquid storax* is procured, as well as from the liquidamber. There is a storax from Bogota, but its source is unknown.

STYRIA, THE DUCHY OF, in Austria, is situated between 45° 54′ and 47° 50′ N. lat., and between 13° 30′ and 16° 25′ E. long. It is bounded on the north and northwest by the archduchy of Austria, on the west by Illyria, on the south by Illyria and Croatia, and on the east by Croatia and Hungary. The area is about 8500 square miles, or about one-fourth of that of Scotland, and the population amounts to 950,000 souls. The northern and western part of the country is covered with high mountains, which are called by the general name of the Styrian Alps. Properly speaking, they are two great branches of the Julian Alps, which extend to the east; one of these branches separates the valley of the Ens from that of the Mur, runs south-east, as far as the Wild Alps, to the west of Semmering, where it joins the Noric Alps, and then proceeding in a south-easterly direction forms the boundary towards Austria below the Ens, extends into Hungary, and gradually declines to the plain of Oedenburg. The other branch divides the valley of the Mur from that of the Drave, and forms the frontier between Styria and Carinthia. To the south of the Mur the Bacher chain is the continuation of this branch. A third mountain-chain runs from Loibl to the Save, and forms on that side the boundary towards Carinthia. None of the mountains rise to the line of perpetual snow; on the north-western frontier there are some glaciers, but still below the absolute snow-line. The highest mountains that have been measured are the Grössenberg, 8381 feet; the Eisenhut, 7676 feet; the Grimming, 7540 feet; the Stangalpe, 7140; the Hochschwab, 7154; and the Bachstein, 7008 feet, above the level of the sea. The southern and eastern part of the province contains few lofty mountains, but there are many of moderate elevation, and numerous gentle eminences, some of which are separated by extensive valleys. In conformity with the physical character of the country, it is divided into Upper Styria, which comprises the smaller north-western portion, which is entirely mountainous, and Lower Styria, which is the south-eastern, and larger, lower, and level portion. 'Styria,' says Blumenbach, 'is properly a mountainous country, but with the richest diversity; a wild, romantic, beautiful region, which surpasses the magnificence and variety of the finest English park. Throughout the whole country there is an alternation of lofty peaked rocks and perpendicular walls, flowery meadows, lovely valleys, dark impenetrable forests, rushing waterfalls, peaceful lakes, castles, and villages.' The country has numerous rivers, all of which flow into the Danube, and for the most part by an east course. The principal rivers are, 1st, the Mur, which rises in a lake, traverses the centre of the country for about 180 miles, is joined by many smaller rivers, and enters Hungary at Maut; 2nd, the Drave, which enters Styria below Hohenmauthen, and enters Croatia at Fridau; 3rd, the Ens; 4th, the Raab. The Save only touches the southern frontier, towards the government of Laibach, but is joined by the Sän and the Sotla, the latter of which bounds for some extent the south-eastern frontier towards Croatia. The Mur, Drave, Ens, and Save are navigable by boats. There are no large lakes, but many small ones. The largest are, the Grundelsee, above 718 Austrian acres in extent, in many places 60 fathoms deep, and 2031 Paris feet above the level of the sea; the Altenausseersee, 358 acres in extent, and 2280 Paris feet above the level of the sea. The country abounds in cold, warm, and hot mineral-springs, the best known and most celebrated of which are the chalybeate waters of Rohitsch, the sulphureous and alkaline springs of Neuhaus, the alkaline waters of Sekau, and some others.

Like all countries that abound in limestone mountains, Styria has numerous caverns, the most interesting of which is the Mirnitz cavern.

Soil and Climate.—The air in the mountainous part is bleak, though pure; in the valleys of Lower Styria the temperature is much milder, and the vine and maize flourish. The fertility of the soil is various. A great part of Upper Styria consists of bare naked limestone rocks and sterile mountains, but Lower Styria has many very fertile tracts.

Natural Productions.—These are, the common domestic animals, with game, poultry, fish, and bees. The breeding of cattle is very general. The animals are well-shaped, but small, and, as usual in the Alps, are driven in summer to the highest parts of the mountains, and brought back to the plains in autumn. Sheep are not numerous, and the horses are more fit for draught than for the saddle. The vegetable products are very diversified: wheat, rye, barley, and oats, though not abundant in Upper Styria, are of remarkably fine quality. In Lower Styria there are likewise maize, millet, and buckwheat, pulse of various kinds, and culinary vegetables; potatoes, the culture of which was introduced about the middle of last century, are now very extensively cultivated. Of oleaginous plants there are the poppy, sunflower, and rape-seed. Very little hemp is grown; some flax is raised, but not sufficient for home consumption. Of late years hops have been cultivated with success. Wine and fruit are among the chief productions. Timber is a very important article. The principal kinds of timber are the oak and the beech in Lower Styria; the pine, fir, chesnut, walnut-tree, red yew, stone-pine, lime, white poplar, and willow are scattered over the whole country, but for the most part they grow in forests. The great wealth of Styria however consists in its mines, which are confined to the smaller mountainous portion of the country. The most important minerals are—silver, copper, lead, iron (540,000 cwt. a year), alum, cobalt, sulphur, salt, marble, and coals.

Manufactures and Trade.—The manufactures of the country are chiefly of mineral products, the most important of which is iron. The iron-mines in the Erzberg, in the north of Styria, were well known to the Romans. This mountain does not contain the ore in veins or strata, but presents a solid mass of iron-ore, which has been wrought without interruption for eleven centuries.

Styria does not manufacture the whole of the iron produced; the surplus is exported partly to the archduchy of Austria, where the extensive iron-manufactories are chiefly supplied from Styria, and partly, by way of Vienna and Trieste, to France and England. There are a few manufactories of linen, cotton, woollens, and silk, but none of considerable importance. There is a very brisk trade between Upper and Lower Styria; the latter supplies the former with corn, wine, and tobacco, and receives in return iron, timber, and salt. The exports to other countries are chiefly cattle, steel, iron, copper, and lead, to Austria, Hungary, and European Turkey, scythes (a million), sickles (200,000 in a year), steel and some other iron-wares, to Italy, France, Poland, and Russia. Among the smaller articles of iron, several millions of Jew's-harps are annually exported. The imports are very considerable, consisting chiefly of fine cloths, linens, cottons, silks, and jewellery, from Vienna, and colonial produce from Trieste and Fiume. The transit-trade between Italy and Germany, from Vienna to Trieste, is very important. This trade is greatly facilitated by the good roads, especially that between Vienna and Trieste, from which other great roads branch off to the Tyrol, to Linz, to Ofen in Hungary, and Carlstadt in Croatia. The principal commercial towns are Grätz, Pettau, Leoben, Rackersburg, and Marburg. The government is like that of the other Austrian hereditary states; the emperor has the title of duke of Styria. The parliament, or estates, as they are called, consist of four orders—the higher clergy, the nobility, the deputies from the landholders, and the deputies from the towns.

Religion and Education.—The inhabitants consist of two nations: Germans, who are the majority (above two-thirds), and Wends, who are of Slavonian extraction, and speak their own language. The Germans, who inhabit all Upper Styria, the circle of Grätz, and a small part of that of Marburg, are a tall, handsome, robust, good-tempered, and industrious race. The Wends are weak, thoughtless, dissolute, and bigoted. The great majority of the people are of the Roman Catholic religion, the Lutherans not being above 3000 in number. The establishments for education are, the University, two theological schools in convents, four gymnasia with sixty-eight professors and about 1800 students, and 627 Roman Catholic and 4 Protestant schools. There are, besides, several other schools for special purposes. The hospitals, infirmaries, and other charitable institutions are very numerous.

History.—Pliny and Strabo are the first authors who give any account of this province. The inhabitants were completely uncivilised, and harassed the adjoining provinces, till the reign of Augustus, when the country was subdued by Tiberius, and the eastern part incorporated with the province of Pannonia, and the western with that of Noricum. The country was even then celebrated for its iron, steel, and cattle; subsequently industry flourished in the towns, especially in Celeja (Cilly), Petovium (Pettau), and other places. Christianity penetrated early into this country, and spread so rapidly, that episcopal sees were established at Pettau and Cilly; but the irruption of the northern hordes put an end to the prosperity of the country, which was successively overrun by the West Goths, the Huns, the East Goths, the Heruli, the Lombards, the Franks, and other barbarians. In the sixth century the Slavonians established themselves in Lower Styria, and afterwards, when they had expelled the Avari, in Upper Styria, till they were overpowered by the Germans. Charlemagne, having conquered Styria, divided it among several counts: under his successors the country suffered from the internal discords of its chiefs by the incursions of the Bulgarians, and by the invasion of the Magyars, from whose yoke it was delivered by the victory obtained over them by the emperor Otho the Great, in the year 955. The country was divided afterwards into a number of principalities, of which that called the county of Steyer was successively enlarged to its present extent under rulers who bore the title of margraves, and afterwards of dukes, till it was annexed, at the end of the twelfth century, to Austria, with which it has ever since been united.

Various events checked the prosperity of the country, such as the repeated invasions of the Magyars and the Turks, famine, pestilence, the expulsion of the Jews, and the insurrection of the peasantry. The doctrines of the German reformers had been adopted, about the year 1530, by so great a proportion of the inhabitants, that they were openly preached and taught in the churches and the numerous schools which the Protestants had established. At the diet held at Augsburg in 1547, Baron John Ungnad, at the head of the Styrians, applied to the emperor and empire for the free exercise of religion, which the Protestants did not however obtain till the diets held at Bruck, in 1575 and 1578, when the archduke Charles II., being sorely pressed by the Turks, was obliged to grant it, the greater part of the nobility, half of the citizens, and a considerable number of peasants having already embraced the new doctrines.

The rapid spread of the Reformation had been greatly promoted by the school at Grätz, founded in 1568, while the archduke Charles was absent in Spain, which the estates of the duchy converted, in 1573, into a high school for Protestants, and provided it with professors from foreign countries, eminent for their learning. The archduke Charles had already called in the Jesuits to his aid, in 1570, and he assigned them a residence in 1573; on the 12th of November in the same year, he founded the Catholic high school at Grätz, and, at the instigations of his wife Maria of Bavaria, who was full of zeal for the Romish religion, he took measures to restrict the principles of the Reformation, which his son Ferdinand II. prosecuted with so much energy and rigour, that a hundred years after the first appearance of the Protestant preachers in the country, all Styria was re-annexed, by violence, to the Romish faith. Supported by the garrison of the citadel of Grätz, which was considerably increased for the purpose, Ferdinand revoked his father's grant of the free exercise of their religion, and commanded the estates to dismiss the Protestant clergymen and teachers from all the churches and schools within fourteen days. On the 28th September, 1598, the teachers were strictly commanded to leave the city of Grätz on the same day before sunset, and the hereditary estates within a week, on pain of death, and never to return to them. The Protestant high school was closed; a Romish anti-reformation commission was appointed, which boasted of having burned no fewer than 40,000 volumes of Protestant books; and all Protestant citizens were enjoined either to embrace the Romish religion, or to sell their property, and with the proceeds, after the deduction of one-tenth, likewise to leave the country. Many professors of the doctrines of the Reformation abjured their faith, in order to remain in the land of their fathers; 30,000 others, of the richest and most distinguished families, and among them many of the noblest houses, left their native country; and lastly, others concealed their opinions, and cherished them in silence from generation to generation, for two centuries and a

half, till the toleration edict of Joseph II. allowed them openly to profess their faith.

(Hassel; Stein; *Die Oesterreichischer National Encyclopädie; Conversations Lexicon;* Blumenbach, *Gemälde der Oesterreichischen Monarchie*, &c.)

STYX (Στύξ or Στυγὸς ὕδωρ), a small stream in the north of Arcadia, which is now called Mauronero. According to Herodotus (vi. 74) its source was in the Arcadian town of Nonacris. Vitruvius (viii. 3) states that its water destroyed all brass, iron, and silver vessels which were filled with it.

In the antient mythology the Styx was believed to be the principal river of the lower world, round which it flowed nine times. (Virg., *Æn.*, vi. 439.) It was believed to be an arm of the river Oceanus, which flowed round our earth, and the river Cocytus was thought to be a branch of the Styx. When the gods of the antients took a great oath, they always swore by the water of Styx, and awful punishment awaited him who swore falsely. The divinity of the river Styx was a nymph of the same name, who dwelled at the entrance of the lower world in a spacious grotto supported by silver columns. (Hesiod., *Theog.*, 778.)

SUABIA, one of the ten circles into which Germany was divided previously to 1806, comprehended the south-western part of Germany, one of the most beautiful and fertile tracts of the whole empire, traversed by the Danube from the south-west to the north-east, by the Black Forest on the west, and by the Alps in the interior and on the south. It was situated between France, Bavaria, Switzerland, Franconia, and the circles of the Rhine, and had an area of 13,000 square miles, with 2,200,000 inhabitants. Its chief natural productions are corn, wine, and fruit, and in the mountainous parts minerals, and timber, which is floated down the Neckar and the Rhine to Holland. The country of the Suevi, from whom the name of Suabia is supposed to have been derived, was more extensive than the modern circle. Christianity was introduced at the beginning of the seventh century by the Irish monk Columba. In the year 1080 Henry IV. gave the duchy of Suabia to Count Frederick of Hohenstauffen, the ancestor of the emperors of the house of Suabia. Frederick did not however obtain peaceable possession of the duchy till 1096. Under his distinguished successors, the Suabians were the richest, the most civilised, and the most respected of all the nations of Germany. But when the Italian wars and the contest with the Guelfs had broken the power of the house of Hohenstauffen, and it became extinct on the execution of Conradin in 1268, their vassals, cities, prelates, and counts made themselves independent. Many Suabian cities joined the Rhenish Federation, founded in 1254, and Würtemberg in some measure took the place of the extinct duchy of Suabia. This is not the place to enter into the details of subsequent events, the sufferings of the people from repeated wars, from civil discords and disputes between princes and their subjects, till the final dissolution of the antient constitution of the empire, and the partition of the country among Würtemberg, Bavaria, Baden, the princes of Hohenzollern, the prince of Lichtenstein, Austria, and Hesse-Darmstadt. The largest cities are Augsburg, Stuttgard, and Ulm.

The very name of Suabia has disappeared from the maps and gazetteers of Germany, and was only revived about three years ago by the king of Bavaria, who restored to the circles of the kingdom the antient historical names, and gave that of Suabia to the circle of the Upper Danube.

(*Conversations Lexicon;* Hübner, *Zeitungs Lexicon; Weimar Almanach*, &c.)

SUAKIN or SOUAKIN, a town or seaport in Nubia, on the west shore of the Red Sea, is in 19° 4′ N. lat. and 37° 30′ E. long., at the extremity of a narrow inlet, about twelve miles in length and two in width. The entrance of the bay is only about sixty fathoms wide, but it opens gradually to two miles. With northerly winds it is very difficult to enter or to leave the bay. But when the winds are from the south, there is a regular land-breeze every morning, which obviates all difficulties. The bay has a sufficient depth of water, generally varying between fifteen and nineteen fathoms. At the bottom of the bay there are several islands, on one of which the town is built. The town is separated from its suburb, called El Geyf, which stands on the mainland, by an arm of the sea about five hundred yards wide. The harbour, which is on the east side of the town, is formed by a projecting part of the continent. The arm of the sea on the west side affords no anchorage for ships of any size. The islands and all the surrounding country are sandy, and produce only a few shrubs or low acacias. The houses of the town have one or two stories, and are constructed of blocks of madrepores. They have a neat appearance, but the greater part of them are falling to decay. The suburb El Geyf is rapidly increasing in size and population, and is now larger than the town itself; but there are few houses of stone, the greater part of the dwellings being formed of mats or rushes, like those of the Nubian Bedouins. Suakin has three mosques, and El Geyf one mosque. The water of the wells, which are about half an hour from El Geyf, is tolerable, but in none of them is it good. Burckhardt estimated the population of Suakin at about 8000, of whom 3000 live upon the island and the rest in El Geyf.

Suakin is the most important trading-place on the west shore of the Red Sea. The inhabitants have no other pursuit than commerce either by sea or with the contiguous countries of Eastern Africa. They export the commodities which they receive from Eastern Africa to all the harbours of Hejaz and Yemen, down to Mocha, but chiefly to Jidda and Hodeyda. Many of the merchants go to Sennaar to buy their goods, and, after returning to Suakin, they perform the journey to the Arabian coast, but others sell their African merchandise to the traders of the town, by whom they are exported to Arabia. They bring from Sennaar, Kartoun, and Shendy, slaves, gold, tobacco, incense and ostrich feathers; from Beled-el-Taka, a country situated on the east of the river Atbara, great quantities of dhurra; and they collect in the country to the west of the town larger numbers of water-skins, leathern sacks, and tanned hides, all which articles find a ready sale in the ports of Arabia. The hides are tanned by the Bedouins who live in the neighbouring mountains, and are used in Arabia to make sandals. A large quantity of butter in a liquid state, the only form in which it is used in this country, is likewise exported to Arabia, as well as mats made of doum-leaves, which are partly used to cover the floors of the mosques at Mecca and Medina, and partly bought by the pilgrims for the purpose of kneeling upon when they pray. These two articles are also obtained from the Bedouins in the mountains near Suakin. Horses and dromedaries are brought from the countries on the banks of the Nile, and sent to Hodeyda. At Jidda the Suakin merchants purchase all the Indian goods which are wanted for the African markets and the consumption of their own town, as dresses and ornaments for women, household utensils, and several kinds of provision for the table, such as Indian sugar, coffee, onions, and particularly dates, which are not produced in any part of Eastern Nubia. Much iron is also imported for lances and knives, which are manufactured by common smiths, who are the only artisans at Suakin, except masons and carpenters, and furnish these weapons to all the Bedouins in a circuit of fifteen days' journey. The trade by sea is carried on principally in ships belonging to people of Suakin and Jidda; they are almost entirely occupied in sailing between the two coasts. They are often manned by Bedouins, but more commonly by Somaulys from the African coast between Abyssinia and Cape Guardafui, who are the best sailors in the Red Sea. The number of black slaves annually brought through Suakin to the coast of Arabia amounts, according to Burckhardt, to between 2000 and 3000, and about an equal number are sent there from Massowah in Abyssinia, where about 3500 are annually shipped to Mocha. Many pilgrims, mostly negroes from Beled-el-Sudan, who have been converted to the Mohammedan faith, pass annually through Suakin in going to or returning from the holy cities of Arabia.

The inhabitants of Suakin, like those of all the harbours in the Red Sea, are a motley race, but the majority of them are descendants of natives of Hadramaut, and principally of the town of Shabher, the harbour of that country in the Indian Ocean; they are called Hadherebe. The other inhabitants are called Suakiny, and consist of individuals of the Bedouin tribes of Hodendoa, Amorer, the Bishareen, and others of Arabian and of Turkish origin. The Bisharye language is generally spoken in El Geyf, but the inhabitants of the town speak the Arabic as their native language, and with the Jidda pronunciation. The island contains a public school.

(Lord Valentia's *Voyages and Travels to India, Ceylon, the Red Sea, &c.*; and Burckhardt's *Travels in Nubia.*)

SUA'REZ, FRANCIS, eldest son of Gaspar Suarez of Toledo, and of Antonia Vasquez of Utiel, was born at Granada, where his father practised as an advocate, on the 5th of January, 1548. After receiving a good elementary education, he was sent to Salamanca to study law in 1562. The members of the Society of Jesuits, founded about 20 years before, were at this time labouring to extend the ramifications of their order with the full force of the enthusiasm which gave it birth. John Ramirez, as Suarez asserted in after-life, induced no less than five hundred students of Salamanca to devote themselves to a religious life by the fervour of his preaching on Quadragesima Sunday in 1564. Suarez himself was among the number. He experienced considerable difficulty before he could induce the superiors of the order to admit him to probation; and even after John Suarez, the provincial-general, had resolved to receive him, on account of his possessing qualifications which appeared capable of being turned to account, remonstrances were offered against this determination by more than one member of the Society. During the period of his noviciate Suarez eminently distinguished himself by that obedience and humility, and disregard of self, which it was one of the great objects of the founders of the order to impress upon their disciples; at the same time that something about the young man showed this submission to be the consequence not of a weak or timid disposition, but of a powerful spirit of enthusiasm enforcing self-abasement. Before the probationary two years were completed, he was made to begin his philosophical studies. Pursuits so new and so alien to his impassioned temper at first excited in him nothing but sentiments of weariness and disgust; he made little progress, and earnestly begged of his superiors to allow him to desist from studies for which he was convinced he had no capacity. A more favourable opinion of his talents continued notwithstanding to gain ground among the order, and Martin Guttierez, then in high estimation among his brethren, was wont to say, pointing to Suarez, 'God intends, through the instrumentality of that brother, to magnify the church, and do honour to the Society.' Deferring in this, as in everything, to the directions of his superiors, Suarez toiled through the usual course of philosophical study, but apparently with indifferent success; for when advanced to the theological classes, in which he took more pleasure, he found his progress obstructed by his deficiency in the preparatory branches of instruction. With the powerful impassioned will which enabled him to wrest, as it were, by his pertinacity, from the reluctant fraternity admission into their Society, he now laboured to make up his deficiencies. With this view he compiled for himself a system of metaphysics, the same which, published at a later period, with a very few finishing touches, elicited much applause. Having completed this task, he devoted the whole of his private hours to self-tuition in the science of casuistry. Having taken his vows at the usual time, Suarez was immediately employed in the educational department. He taught philosophy for a short time at Segovia, and next theology, for several years, at Valladólid. In 1580 he was called to Rome, and lectured on theology there, in the College of the Society, with great applause for eight years. The climate of Rome affecting his health, he obtained leave to return to his native country, in 1588, where he was appointed professor of theology in the University of Alcala, a situation which he held till 1596. On quitting Alcala he lectured for a year at Salamanca. The University of Coimbra in Portugal had, in the meantime, by repeated and urgent solicitations, obtained of Philip II. that Suarez should be appointed its principal professor of divinity. On his way thither Suarez received the degree of doctor in theology from the University of Evora. He arrived at Coimbra in 1597, and spent there the remaining twenty years of his life. His lucid arrangement, extraordinary memory, and fervid eloquence, rendered his lectures eminently popular. But the manner in which his contemporaries speak of him is calculated to leave an impression that his striking personal character had quite as great an influence in raising him to fame as his intellectual powers. He shunned rather than sought applause; he was indefatigable in his endeavours to render himself serviceable to others; he was guarded in his language, even when expressing himself under strong excitement; he was abstinent, both in regard to meat and drink; and the same enthusiasm which impelled him 'to take the order by storm,' continued to show itself unabated to the last, in his eager discharge of devotional offices. Of all his works, that which excited most attention in this country was, as might have been expected, the controversial treatise called forth by the defence of the oath of fidelity published by James I., 'Defensio Fidei Catholicæ et Apostolicæ adversus Anglicanæ Sectæ Errores, cum Responsione ad Apologiam pro Juramento Fidelitatis et Præfationem Monitoriam Serenissimi Jacobi, Angliæ Regis.' It appeared at Coimbra in 1613. It is the work of an enthusiastic recluse, who, deeply convinced of the truth of his principles, and accustomed to teach them as abstractions to youth, not to attempt to practise them amid the hindrances of real life, pursues them out to all their consequences with a bold and severe logic. The language is decorous, but the conclusions are stated without reserve or softening, and at the conclusion of each chapter an affectionate exhortation is addressed to King James, begging him to acknowledge their truth, and submit to them in practice. The king replied, not by publishing a rejoinder, but by having the book condemned to be burned in London. By order of the Parliament of Paris, it suffered the same fate in that capital in 1614. It was not such a work as political leaders in the court of Rome would have ventured to put forth; but it was such a one as they rejoiced to see put forth by their abstract thinkers, for whom they could apologise to sovereigns as well-meaning men, but ignorant of the world, and therefore not worth minding, at the same time that they reckoned, and not without cause, upon the good effects to be produced on public opinion by the single minded expression of a sincere enthusiast. The Romish politicians were in this perhaps no more insincere than secular politicians. With Suarez however it was perfect earnestness and conscientious conviction. When informed of the treatment experienced by his book, he expressed the enthusiastic wish that his body had enjoyed the privilege of bearing testimony to his faith by suffering the same fate; and he was in truth the stuff of which martyrs are made. His systematic works were after his death collected and published under the auspices of the Society in twenty-four volumes. The most important are:—four volumes on the chief end of man, in which he treats of the will, good and evil, virtue and vice, and sins; a volume on laws, and God viewed in his capacity of legislator; four volumes on grace, viz. on justification and the necessity of grace, on actual grace and the means of grace, on habitual grace and its effects, on the true meaning of efficaceous means of grace, &c.; two volumes of metaphysics, and one of commentaries on different works of Aristotle. The chief merits of the writings of Suarez are order and precision. His system is a modification of Molinism, with a view to obviate some of the objections urged against it by the strict adherents to the views of St. Augustin. The controversy between the Jesuits and the sectaries of that father, like that between the Arminians and Calvinists in the Reformed church, is parallel to the controversy between necessitarians and those who maintain the freedom of human action The scientific disputants appeal to human reason; the theologians, to revelation: with the one, it is an inquiry into the constitution of man; with another, into the will of the deity the former must decide by investigating natural phenomena and reasoning upon them; the latter, by critically investigating the language in which the revelation to which they appeal is couched. The qualities of mind elicited in theological controversy are acuteness and logical neatness. These are to be found in Suarez, nor is there anything in his writings to warrant the opinion that he possessed higher intellectual attributes. He was something more than a mere logician and verbal critic; but his greatness consisted in his elevation of sentiment, empassioned temperament, and energetic will. Suarez died at Lisbon, whither he had gone to make arrangements for the publication of his volumes on Grace, on the 25th of September, 1615. He is reported to have said on his death-bed, 'I did not think it was so easy to die.'

(*Life*, prefixed to the edition of Suarez's *Works*, published at Venice in 1740; *Bibliotheca Nova Scriptorum Hispanorum*, v. 'Franciscus Soarez.')

SUARROW-NUT. [CARYOCAR.]

SUBAPLYSIA'CEA, M. de Blainville's name for the first family of his MONOPLEUROBRANCHIATA, an order which he defines as having branchial organs of respiration situated at the right side of the body, and more or less completely covered by a part of the operculiform mantle, in which a shell, which is flat, or more or less involved with a very large

and constantly entire opening, is often developed; the tentacles null, rudimentary or auriculiform.

The following is M. de Blainville's definition of the family character of the Subaplysiceans:—

Two or four tentacular appendages to the head. Orifices of the organs of generation but little or not at all distant from each other, and without an intermediate external groove.

The genera comprised under this family are BERTHELLA, *Pleurobranchus* and *Pleurobranchidium*. [SEMIPHYLLIDIANS.]

The other families of this order are—2, *Aplysiacea*; 3, *Patelloidea*; and 4, *Akera*.

The *Aplysiacea* are defined as having a body not divided, or forming a single soft fleshy mass; four tentacular appendages, which are constantly very distinct, flattened, and auriform; mouth in the form of a vertical slit, with two lateral subcorneous labial plates, and a cordiform tongue rough with denticles; eyes sessile, between the two pairs of tentacles; branchiæ covered with a sort of operculum; orifices of the generative apparatus more or less distant, and united together by an external furrow.

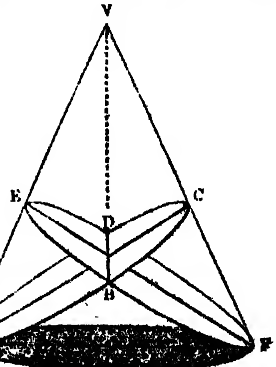
Shell null or incomplete, constantly internal.

The genera in this family are, according to M. de Blainville—*Aplysia*, *Dolabella*, *Bursatella*, *Notarchus*, and *Elysia*.

The third family, *Patelloidea*, consists of the genera *Umbrella*, *Siphonaria*, and *Tylodina*. The two first of these forms are treated of in the article SEMIPHYLLIDIANS.

The fourth family, *Akera*, comprises the genera *Bulla* [BULLADÆ], BELLEROPHON, *Bullæa*, *Lobaria*, *Sormetus*, *Gasteroptera* [BULLADÆ], and *Atlas*.

SUBCONTRARY. This word is applied particularly to the sections of a cone, in a manner which, without interfering with that use, would allow of its definition being generalised as follows:—When a figure or solid is symmetrical, so that equal lines or polygons can be drawn on two different sides, those equal lines or polygons may be called *subcontrary*. Thus in Euclid, i. 5, the equal lines, which are obliquely deflected from the two ends of the base of the isosceles triangle, are subcontrary. In a right cone every section has its subcontrary, except only the circle which generates the cone, and its parallels. Let V be the vertex of an oblique circular cone, and ABCD the circle on which it is described. Let the plane VAC be that which passes through the centre of the circle perpendicularly to its plane. Then the cone is exactly the same on one side of the plane VAC as on the other; and if a plane AGF be drawn through A perpendicular to the line which bisects the angle AVF, the section AGF is such that either half would take the place of the other, if it were to make a half revolution about AF. It is then an ellipse, of which AF is one of the principal axes; and the middle point of AF, falling in the line which bisects AVF, is the centre. Consequently every section of this cone has a subcontrary section, except only those which are parallel to AGF. Hence the generating circle ABCD has a subcontrary circle EBFD, made by taking the line EF subcontrary to AC, and drawing through EF a plane perpendicular to the plane AVF. The angles VEF and VCA are equal, as also VAC and VFE.



In the limited use of the word subcontrary, no sections are considered in this light except the two circular sections of an oblique cone. Consequently when subcontrary sections are mentioned, these circular sections are understood. The proofs given of the existence of these subcontrary sections usually conceal the fact of all cones described upon a circle being symmetrical when produced in every direction, and seem to make the existence of a second circular section a sort of accident of the circle, as if no other section had its subcontrary.

Since all parallel sections of a cone are similar, it follows that through every point of the surface two subcontrary circles can be drawn. The surfaces of the second order generally have the same property. [SURFACES OF THE SECOND ORDER.]

SUB-DOMINANT, in Music, the fourth of the key, mode, or scale. Thus, in the key of C, F is the Sub-Dominant.

SUBDUPLICATE, SUBTRIPLICATE, &c. [RATIO, p. 309.]

SUBERIC ACID, an artificial substance produced by treating rasped cork with diluted nitric acid; the cork is slowly dissolved, and a fatty substance is formed, which floats on the surface of the fluid. The solution is slowly evaporated till it thickens, and the residue is treated with about eight times its weight of water, by which an additional quantity of fatty matter separates. When the solution is filtered, suberic and oxalic acids separate, the former in the state of a white powder; this is to be saturated with ammonia, and the suberate of ammonia formed being decomposed by an acid, the suberic acid precipitates in the state of a white powder, which is to be washed with cold water. Suberic acid may also be obtained by treating margaric, oleic, or stearic acid with nitric acid. The properties of this substance are, that its acid powers are but feeble; it is very soluble in boiling water, and the greater part of it is deposited from the solution on cooling in the form of a white powder; it is soluble also in anhydrous alcohol; fuses at about 300°; and sublimes in acicular crystals.

According to Laurent, it is composed of—

Seven equivalents of hydrogen	7	or	8·05
Eight equivalents of carbon	48	..	55·17
Four equivalents of oxygen	32	..	36·78
Equivalent	87		100·

The suberates are not an important class of salts; we shall therefore mention them briefly. Suberate of ammonia is soluble in water; the suberates of potash and soda are deliquescent, and fusible without decomposition: those of lime, barytes, strontia, magnesia, alumina, and manganese are more or less soluble: protosuberate of iron is a white precipitate; the persuberate is a brown one: the suberates of tin, zinc, mercury, and silver are white insoluble substances: that of cobalt is red, of copper blue-green, and uranium yellow.

SUBERIN is a peculiar substance so named by Chevreul, as obtained from common cork, the epidermis of the *quercus suber*. When ten parts of cork have been treated with water, alcohol, æther, hydrochloric acid, potash, &c., there remain seven parts, which are suberin, possessing the following properties:—it is very inflammable; by distillation it yields water, a colourless oil, and afterwards a yellowish one, all of which are acid; then ammonia and a fatty crystallized substance are produced, and various gases are disengaged, while charcoal equal to one-fourth of the suberin remains in the retort.

SUBJECT, SUBJECTIVE.—These words, with their correlatives Object and Objective, are now again restored to English philosophical language, through the medium of the German writers. The Subject is in philosophy invariably used to express the mind, soul, or personality of the thinker—the Ego. The Object is its correlative, and uniformly expresses anything or everything external to the mind; everything or anything distinct from it—the non-Ego. The universe itself, when considered as a unique existence, is an object to the thinker; and the very subject itself (the mind) can become an object, by being psychologically considered.

The distinction is most important. The exact distinction between the terms subject and object was first made by the schoolmen; for by the Greeks the word ὑποκείμενον was equivocally employed to express either the object of knowledge (the *materia circa quam*) or the subject of existence (the *materia in qua*). These correlatives, subject and object, correspond to the first most important distinction in philosophy, viz. the original antithesis of self and not-self. These terms, in their substantive and adjective forms, passed from the schools into the scientific language of Tilesius, Campa-

nella, Gassendi, Descartes, Spinoza, Leibnitz, Wolff, and others.

These terms however gradually lost their primary signification, and this owing to the ambiguous manner in which the terms were used. Besides its primary signification, object became metaphorically *motive, end, final cause*, &c., by a common change in all language, of the metaphor into a real signification. Subject also became synonymous with object, and probably the logical terms 'subject of predication' facilitated this confusion. Be this as it may, the extreme want of precision with which the words are used, may be seen in the very common instance of calling anything 'a subject of investigation.'

SUBLIMATION, a chemical operation effected by the application of heat to certain bodies; it is essentially similar to distillation in principle, but differs from it in the nature of the substances to which it is applied. In distillation liquids are converted into vapour, and condensed into the same form by the cooling agency of water; whereas in sublimation solid bodies are vaporized, and afterwards reassume the solid state, in general merely by the cooling power of the air, without the assistance of cold water.

Sublimation is usually conducted in one vessel, the product being deposited in the upper part of it in a solid state, while the impurity remains in the lower. In small experimental researches a Florence flask answers perfectly well, and a good exemplification of the process is that produced by heating iodine in it: a purple vapour rises, which almost immediately condenses in small brilliant dark-coloured crystals in the upper part of the flask, the impurity remaining in the lower.

Sublimation is extensively employed, and for two different purposes; the simplest case is that of using it for purifying a substance, camphor for example, in which the pure camphor is vaporized, and condenses in the upper part of the vessel, while the impurities remain in the lower part.

In preparing corrosive sublimate and calomel, these substances are formed and sublimed by the same operation: in general large green-glass vessels, called *boltheads*, are used for calomel and corrosive sublimate; while for camphor very thin flint-glass vessels are used, which are called *bombolos*, from the Italian *bombola:* in both cases a vessel is broken after each operation, to obtain the product. Among other substances procured by sublimation is benzoic acid, formerly called *flowers of benjamin*. This acid is sublimed in much larger vessels, and not usually made of glass; while the vapour of sulphur is condensed in a large chamber, or sulphur-house, and adheres to the walls in the form of a fine powder, and known by the name of *sublimed sulphur*, or *flowers of sulphur*.

SUBLIME. (Geometry.) It may be worth while to state in few words, and to prevent a reader of the older mathematicians from imagining that they spoke rhapsodically, that the term *sublime geometry* was technical, meaning the higher parts of geometry, in which the infinitesimal calculus or something equivalent was employed.

SUBLIMITY has two significations: one, that of the quality or circumstance in objects, which raises the emotion named sublimity; the other, that of the emotion itself. In no modern philosophy, except the Scotch, could this distinction in language, for the sake of convenience, have been taken for an equivalent distinction in thought. Yet this distinction has been combated as an error, by almost all the Scotch writers—Kames, Stewart, Brown, Alison, Jeffrey, &c.—when the truth is, no such error was ever entertained by any correct thinker. The generality of people may conceive beauty and sublimity to be qualities of objects without respect to their emotions, as they regard sound, taste, smell, &c. to be qualities of objects without respect to the senses; for the law of the common mind is eminently what the Germans call an objective tendency, that is, a tendency to believe in its own sensations and emotions as *things* distinct from themselves, but no philosophical thinker of the last century has ever fallen into this error, and when Dr. Thomas Brown refutes, with so much pretension, the 'theory of the one universal sublime as a specific object to which there is a corresponding faculty of perception in the subject, he is combating a chimæra.

But the nature of the sublime, that is, those conditions of objects which invariably excite in us certain emotions, to which we give the common name of sublimity, is a subject of great interest and importance in psychology, and has always been a favourite subject of speculation. We shall briefly notice the more celebrated theories which have professed to embrace and explain all 'those conditions which excite the emotions,' and endeavour to point out their failures.

Longinus, whose work (Περὶ ὕψους) is the most antient, treats only of the sublime in writing. His treatise was meant as a supplement to the work of Cæcilius on the 'Sublime,' in which he says Cæcilius brought a number of instances to show what is the sublime, as if every one did not know that well enough.

Burke's 'Inquiry into the Sublime and Beautiful' was the first attempt to give philosophical precision to our notions of the sublime. His theory is, that the essence of the sublime consists in terror operating either openly or latently; and the delight which is caused by this terror is referred to those principles of human nature which he calls 'passions of self-preservation,' and which turn on pain and danger. These passions 'are simply painful when their causes immediately affect us; they are delightful when we have an idea of pain and danger, without being actually in such circumstances: this delight I have not called pleasure, because it turns on pain, and because it is different enough from any idea of positive pleasure—whatever excites this delight I call sublime.' (*Inquiry*, part i., sect. 18.) 'Whatever therefore is terrible, with regard to sight, is sublime too, whether this cause of terror be endued with greatness of dimensions or not.' (*Ibid.*, part ii., sect. 2.) Nothing can be more explicit than these two passages, nor more accurately exhibit the truth and error of his theory. The error is glaring in the second passage. Terror is often one feeling, exciting, in conjunction with other feelings, the emotion of sublimity, but not always. The stars are sublime, yet there is no terror in the emotion they excite. On the other hand there is a terror in a surgeon about to operate, or in a pedagogue about to flog—but no sublimity. The gallows is very terrible, but not at all sublime. Yet Burke was so chained down by his theory of terror being the ruling principle of the sublime, as to write—'There are many animals who, though far from being large, are yet capable of raising ideas of the sublime, because they are considered as objects of terror—as serpents and poisonous animals of all kinds.' (*Ibid.*, part ii., sect. 2.) Now, when a man asserts that a serpent is sublime, *because* it is terrible, it is evident that he uses the word sublime in a different sense from the rest of the world; otherwise we say a serpent is in no case sublime.

The better to see how independent the sublime is of any danger manifest or implied, let us take a shower of rain and the stars. A shower of rain is certainly not sublime, yet there is danger implied in it, that is, catching your death of cold. The stars are sublime, without a particle of danger either manifested or implied. Terror then is not the ruling principle of the sublime.

That the terrible is often a constituent of the sublime there can be no doubt, and Burke's error consists in seizing this occasional constituent, and declaring it to be the 'ruling principle.' And further, we must observe, that whenever a feeling of terror is found to be a constituent of the sublime, there will also invariably be found another feeling of security, correcting this terror. Thus, when we stand beneath a rock, the terror consists in a natural apprehension of its falling down and crushing us, which apprehension is instantly checked by our feeling of security and confidence of its not falling. If this feeling of security did not momently check the feeling of terror, the effect would be terror only, and not sublimity, and we should escape from it as swiftly as possible. To witness a storm from a place of shelter is sublime, because our terror is checked by the feeling of security; but if the shelter be one which will not probably withstand the violence of the storm, and thus destroys our confidence, or if we be shelterless and fear the storm, then the effect will be that of pure terror, and not that of sublimity. A sleeping lion is sublime, and there is in that emotion a double feeling of security and danger. If the lion awakes, terror alone is the result, and absorbs every other feeling.

So universal is this accompaniment of a feeling of security correcting the feeling of danger in every case of sublimity wherein terror is a constituent, that we are as much justified in asserting that 'a feeling of security, either operating openly or latently, is the ruling principle of the sublime,' as Burke was in his theory of terror. And we might define sublimity as the 'effect of security.' This sounds

ridiculous, but it contains a portion of the truth, and just that portion of it which Burke's celebrated theory possesses. If terror had been found to be an invariable element of the sublime, the correct statement of the theory would have been—'The sublime is the effect of the concurrence of the two feelings of danger and security.' But unfortunately there are many cases in which no feeling of danger can be found to exist. Infinity and eternity are sublime; but although, as he says, 'infinity has a tendency to fill the mind with that sort of delightful horror which is the most genuine effect and truest test of the sublime,' yet it does not necessarily fill the mind with horror; it may or may not, but in either case it is sublime. Helvetius says, 'When God said, "Let there be light, and there was light:" this image is sublime. But should such an image inspire fear? Yes; because it is necessarily associated in our minds with the idea of the Creator of such a prodigy; and being then seized in an involuntary manner with a dread of the author of light, we feel the sensation of a commencing terror.' (*On Man*, vol. ii., p. 227.) Now we contend that although fear would arise from such a train of thought, yet this train of thought is by no means a *necessary* sequence to the image—'God said, Let there be light, and there was light.' It may or may not arise in the mind, but the sublimity produced by the image is not at all dependent upon it. Even admitting that it is a necessary sequence, there are still too many cases of the sublime destitute of terror, not to overturn Burke's theory.

Lord Kames has a chapter in his 'Elements of Criticism,' on the sublime. He says, 'A beautiful object *placed high*, appearing more agreeable than formerly, produces in the spectator a new emotion, termed the emotion of sublimity; and every other emotion *resembling* this emotion of elevation is called by the same name.' He has here the mere etymological notion of sublimity as something elevated. (See Dr. Parr's observations on the derivation of sublime from *su ra limum*, in the Appendix to Dugald Stewart's *Philos. Essays*.) That there is little to be learnt from such an inquiry is evident.

Mr. Knight, in his 'Analytical Inquiry into the Principles of Taste,' puts forth the theory that the sublime is the effect of the influence of *mental energy* exciting a sympathetic energy in the mind of the spectator or reader. The objections to this are the same as those to Burke's theory, namely, that it embraces a portion of the truth, which it would substitute for the whole truth. We have only to reflect an instant, and numberless instances of the sublime arise in which no mental energy is implied. Solitude, for example, is certainly sublime; so are infinity, eternity, Mont Blanc, &c. Mental energy is perhaps a more comprehensive formula for sublimity than terror, but it is still incomplete; and if one instance of sublimity can be quoted which does not contain the element asserted to be its 'ruling principle,' it is obvious that the theory must be erroneous.

Dugald Stewart's 'Essay on the Sublime' is entirely philological, and as such alone worthy of attention.

Dr. Thomas Brown combats the notion of a universal sublime, but avoids the real question altogether. All that is positive in his lecture on the subject is that the sublime and beautiful are not two distinct classes of emotions, but the same class, differing only in degree. 'It is,' says he, 'as in the thermometric scale, by adding one portion of caloric after another, we arise at last, after no very long progress, from the cold of freezing to the heat at which water boils; though our feelings at these two points are as different as if they had arisen from causes that had no resemblance; certainly as different as our emotions of sublimity and beauty.' (*Lectures on Philos. of Mind*, lvii.) Nothing can well be more erroneous than to take an analogy as a proof. Misled by his analogy, Dr. Brown has falsified the whole nature of the sublime, which according to him is but a larger or intenser form of the beautiful, whereas it differs essentially and antagonistically. He takes the instance of a stream gently gliding through fields rich with all the luxuriance of summer, overshadowed at times by the foliage that hangs over it from bank to bank. This is beautiful. He then traces it on to a majestic river, which flows on and deposits itself in the ocean. Here it becomes sublime. And this sublimity he thinks merely the last in the progressive series of emotions, as the boiling-point is the last in the progressive series of ascending heat. 'If we were to contemplate this continued progress, we should have a series of emotions which might at each moment be similar to the preceding emotion; but which would become at last so different from our earliest feelings, that we should scarcely think of them as feelings of one class.' (*Ibid.*)

The answer to this is, that upon a similar principle of analogical reasoning, you might trace the 'progressive series' of feelings which the man underwent from his earliest childhood; and when this series had conducted him to the gallows, you might say that his feelings at that moment were so different from his earliest feelings, that we should scarcely think of them as feelings of one class. Probably not. Nor should we, in our ethical philosophy, class the crimes which brought him to the gallows, with the innocence which commenced the 'progressive series' of his emotions.

The whole of Dr. Brown's lecture on this subject is trivial or confused; and because he is unable to analyse the feeling itself, he boldly pronounces it not to be analysed. 'It is the vain attempt to define what cannot be defined,' he says, 'that has led to all the errors and supposed mysteries in the theory of sublimity. Sublimity is not one emotion, but various emotions, that have a certain resemblance—the sublime in itself is nothing; or at least it is only a mere name, indicative of our feeling of the resemblance of certain affections of our mind, excited by objects material or mental, that agree perhaps in no other circumstance, but in that analogous undefinable emotion which they excite.' We maintain, on the contrary, that sublimity is *one* emotion, not various similar emotions. It is itself complex, made up of various feelings; but it is one specific feeling, which preserves its characteristic throughout the various shades of difference in the objects which excite it. Dr. Brown thinks, because various objects, differing amongst each other, excite separately feelings of sublimity, that therefore what we call the sublime is but the general classification of those feelings under one name: as A, B, C, D, and the rest, are classed under the word alphabet. Now we contend, and shall shortly endeavour to prove, that the sublime, or that emotion which men have consented to call the feeling of the sublime, is ever one, whatever varieties of feeling may concur with it; that is to say, whether power, terror, magnitude, or mental energy, together or separately, form constituents of each individual emotion of sublimity, nevertheless there is always underneath these, one specific characteristic feeling which renders it not merely an emotion of power, or terror, or magnitude, but of sublimity. Thus A, the sublime, is always A. Whether the word be And, Also, Apt, All—whatever be the sequent letters, A remains A unaltered. This one specific characteristic (A), which of itself constitutes the difference between an emotion of sublimity and one of terror, has been sought for by most of the writers on the subject. Burke thought it was the terrible; Helvetius, that it was a terror just begun. Knight, that it was mental energy; Price agreed with Burke; Kames, that it was a sense of elevation; and Alison, that it was association of ideas. Only Dr. Brown was illogical enough to class the repetition of one feeling as a number of different feelings resembling each other. Finding that A was sometimes followed by *lso*, *pt*, and *ll*, as well as by *nd*, he declared that the A in these words 'and, also, apt, all' was not the same letter, but merely resembled each other. But this is a consequence of his dogma of the similarity of the sublime and beautiful, which he declares to differ only in *degree*, whereas they differ in *kind;* and of his notion of a 'progressive series,' whereby the ocean and streamlet excite the same class of emotions.

Mr. Alison's 'Essays on the Principles of Taste' avoid the real question of sublimity, and the same must be said of his eloquent reviewer Francis Jeffrey, who sums up his theory in these words: 'The emotions which we experience from the contemplation of sublimity or beauty are not produced by any physical or intrinsic quality in the objects which we contemplate; but by the recollection or conception of *other* objects which are associated in our imaginations with those before us, and consequently suggested by their appearance, and which are interesting or affecting, on the common and familiar principle of being the natural objects of love, or of pity, or of fear or veneration, or some other common and lively sensation of the mind.' (*Edin. Rev.*, vol. xviii., p. 2.)

The first part of this passage is either a truism or an absurdity. A truism, if it be meant to state that as a mere sensation (without any respect to all the sentient being had

previously undergone, and which that sensation would necessarily excite) an object in itself is not sublime (a truism however which Mr. Alison asserts to be the conclusion on which his speculations rest: chap. v., sec. 6). An absurdity, if it be meant to state that an object has no intrinsic quality capable of exciting that emotion. The size of a rock, for instance, is the condition of its sublimity; so with the cataract—make it a waterfall, and it ceases to be sublime, yet this difference of size is surely an intrinsic quality in the object which excites the emotion?

The fundamental principle of Mr. Alison's theory is 'that all objects are beautiful or sublime which signify or suggest to us some simple emotion of love, pity, terror, or any other social or selfish affection of our nature; and that the beauty or sublimity which we ascribe to them consists entirely in the power they have acquired by association or otherwise of reminding us of the proper objects of these familiar affections.' (*Ibid.*, and Alison's *Essays*, i.)

This theory is in the highest degree vague. It does not discriminate what constitutes the sublime—it does not analyse that complex emotion and draw forth its characteristic, and moreover in its sweeping generality includes much that it cannot apply to. All objects which excite terror are not beautiful nor sublime; neither are all objects which excite pity beautiful, and so of the rest. To discriminate those which are from those which are not, is impossible on this theory. To resolve the emotion of sublimity into association of ideas, is to say that this special emotion is resolvable into the general law of the human mind, but to avoid an analysis or characteristic statement of this special emotion altogether. It is saying that theft is a crime, and referrible to the general law of criminality, without once demarcating what constitutes theft as a crime, distinguished from murder as a crime. Attraction is the law which regulates the descent of an apple, and association of ideas in like manner is the law which regulates the operation of memory and the flights of imagination; yet as memory and imagination are distinct from the general law, as well as from each other, so also is the emotion of sublimity distinct from the emotion of hatred or beauty. Burke, Knight, Kames, and Price endeavoured to ascertain this distinction. Brown overlooked it, and Alison evades it. Had the special law of sublimity been found, and it was then attempted to be classed in its relation to the general law of the mind, the efforts of Mr. Alison and Mr. Jeffrey would have been of great importance; but in the meanwhile it was assumed.

It appears to us that the true method of attaining the knowledge of this special law of emotion, is the method of all psychological inquiries, viz. induction. Before attempting to detect the law which regulates it, we must collect all, or a vast number of instances of the sublime, and analysing the elements of each case, endeavour to discover *one* primal element which is invariably a constituent of the emotion, and without which all the other constituents would not be able to form that special emotion of sublimity.

In noticing the theories of former writers we have found their inductions imperfect; they have selected too few instances, and consequently when we came to select others, these theories were subverted by the mere statement of them. It was sufficient to disprove the theory of terror, to quote one instance wherein the terrible had no place, and the same with the theory of mental energy. But these theories, though incomplete, contain much that is true in their analyses.

In proposing a new theory, founded on a wider range of induction, we may observe that if any one instance of the universally acknowledged sublime can be found in which no such element (as the one we assert to be the ruling principle) be detected, then that single instance is a proof of the incompleteness of our theory, and a more extensive induction will be necessary.

It will be necessary for the sake of clearness to make use of purely mental distinctions in treating this subject, though they are liable to be misinterpreted as real distinctions; accordingly we divide the question of the sublime into three:—1. The material sublime—or the sublime of nature. 2. The moral sublime—or the sublime in human actions and ideas. 3. The emotion of sublimity, which these external things excite in us—or that feeling in the mind which gives to certain phenomena of nature, or deeds of man, the attribute of sublimity. Speaking *objectively*, the exciting cause of sublimity is vastness; speaking *subjectively*, the emotion excited is a sense of insignificance.

I. The material sublime. Examine every case of material sublimity, and the most primitive fact will be found to be vastness; whatever feelings may simultaneously concur, this of vastness is invariable. Mere vastness is sublime. Vastness either of form or of power. Hampstead Heath is not sublime, but Mont Blanc is. The Thames is not sublime, but the ocean is. Yet to show how little terror has to do with the emotion, we all know that there is as much danger on the Thames as on the ocean when it is calm. Solitude is sublime—because it is vast, that is, indefinite. But solitude in a room or garden is not sublime. A cataract is sublime, but not a waterfall, yet the one is only larger than the other. Longinus has remarked that the sight of a small fire produces no emotion, but that the boiling furnaces of Ætna, pouring out whole rivers of liquid flame, is sublime. Burke remarks that all general privations are sublime because terrible, such as vacuity, darkness, solitude, and silence. But they are sublime because vast, not because terrible; for they are not necessarily terrible, and they are necessarily vast, indefinite.

These instances are sufficient to illustrate the principle. It will be observed that there are some which seem more naturally to derive their sublimity from terror than from vastness, as Ætna for example. But our object was to show that vastness was always a constituent, even when other emotions came into play; and as we have already seen instances where terror does not form one constituent, and that when it does form one, it is still accompanied by vastness, so we prove thereby that vastness is the more general fact. Vastness is sublime as vastness; but terror is not sublime as terror. The difference between a shower and a storm is purely quantitative, yet the storm alone is sublime.

II. The Moral sublime. It is obvious that the moral sublime must differ from the material sublime in proportion as mind and matter differ. Hence vastness, which in the external world is superficial (*in extenso*), in the moral world becomes intense (*in intenso*). Intensity of will equals vastness of form or power. Mere intensity is sufficient to produce the sublime. Œdipus is sublime. Lear, who appeals to the heavens, 'for they are old' like him, is sublime, from the very intensity of his sufferings and his passions. Lady Macbeth is sublime from the intensity of her will, which crushes every female feeling for the attainment of her object. Scævola with his hand in the burning coals exhibits an intensity of will which is sublime. So the celebrated 'qu'il mourut' of Horace in Corneille's tragedy, where a father's love is conquered by a more intense feeling of the honour of his country. It will be difficult to find terror as an element of these cases of the sublime. Mr. Knight's 'mental energy' has here more truth; but though a satisfactory explanation of the moral sublime, yet it will not apply to the material sublime.

Such appear to us to be the objective qualities of sublimity, but the peculiar emotion they excite has hitherto been thought undefinable: we shall nevertheless attempt it.

III. The emotion of sublimity. As in considering objectively every case of material or moral sublimity, we found as the primary and invariable fact vastness or intensity, so in considering subjectively every case of sublimity as an emotion, we shall find the primary and invariable fact to be a sense of our own insignificance; of our inferiority to the object, or to the will which prompted the deed; and this sense of inferiority has guided mankind in the employment of a word expressing elevation for sublimity. Mere vastness excites this emotion by exciting a corresponding sense of our smallness. Mere intensity excites this emotion by exciting a corresponding sense of our feebleness. Vary the objects—vary the emotions as you may, there will invariably be this one feeling of comparative insignificance. Take as an example the sublime words of Scripture, 'I am the High and the Lofty One, who inhabiteth eternity.' Nothing can exceed the grandeur of that idea, and he who conceives it conceives also, at the same time, the corresponding idea of his own small and finite nature. In the violent dashing of a cataract, in the roar of the ocean, in the violence of the storm, or in the majestic quiet of Mont Blanc preserving its calm amidst all the storms that play around it, or in the concentrated will of a Scævola, Horace, Brutus, or Œdipus, in all these cases we are moved by a vivid feeling of some greater power than our own, or some will more capable of suffering, more vast in its strength than our feeble vacillating will. It is from this reason that an imaginative mind experiences more emotions of sublimity than another. In

proportion as we comprehend the majesty of nature, or the amount of self-sacrifice in an heroic action, we comprehend our own inferiority to them.

To take another instance of the sublime—a sleeping lion. The grandeur of the lion arises from his known courage and power. He has an intensity of will, and of strength to execute that will, which we feel immensely to exceed our own. But a caged lion is no longer sublime. And why? Because he is conquered. Man has conquered and caged him. His boasted will and strength have not availed him against the power of man. Our feeling of inferiority has vanished. Had the lion-tamers Van Amburgh, Martin, &c. seen a sleeping lion, they would have probably felt little emotion of sublimity.

When Mr. Knight says that the sublime is the effect of mental energy exciting a sympathetic energy in the mind of the spectator or reader, he mistakes a frequent effect for the cause. Sympathetic energy often follows an emotion of sublimity, but not always. It does not follow the emotion of sublimity produced by infinity, eternity, night, or the emotion excited by the passage, 'God said, Let there be light, and there was light.' So far then from 'filling the reader with a glorying and sense of inward greatness,' as Longinus and Knight assert—it fills him with a sense of weakness and inferiority. We admit that any manifestation is delightful for its own sake, but this sympathetic delight is a principle of human nature which does not come within the question of the sublime. But whether sympathetic energy follow the emotion of the sublime or not, it is never the cause of that emotion.

Dr. Brown, Mr. Alison, and Mr. Jeffrey contend for the identity of the sublime, beautiful, and picturesque, led thereto by their resolving them into association of ideas, instead of distinguishing them as special emotions. We contend that the sublime and the beautiful are two very distinct and dissimilar emotions. The beautiful is founded on emotions of the pleasurable, and its varieties are as infinite as the varieties of objects which excite pleasurable emotions. The sublime is founded on an emotion of our insignificance, and its varieties are as limited as the varieties of objects which excite the feeling of insignificance. The beautiful they rightly assert to be the principle of suggesting some past or possible emotion of some sentient being; but they are wrong in asserting the sublime to be the same principle, for the sublime is not founded on any past and pleasurable emotions which the object may excite (as the ruddy cheek of a girl suggests the pleasurable emotions of health and youth, and therefore is beautiful), but is founded on the double feeling of power and insignificance. This emotion may be pleasurable, as almost all emotions are, but the pleasure derived from the manifestation of power is not the foundation of the emotion. The sublime and the beautiful are identified in the more general law of the association of ideas.

In conclusion we may thus sum up our theory. The invariable condition of sublimity in objects, either material or moral, is vastness or intensity. The invariable condition of the emotion of sublimity—that which distinguishes this emotion from every other emotion—is a comprehension of this vastness with a simultaneous feeling of our own comparative insignificance, together with a concomitant sense of present security from any danger which might result from this superior power. The antithesis to the emotion of sublimity is the emotion of contempt.

SUBMARINE DESCENT. Much ingenuity has been devoted from an early period to the contrivance of apparatus for enabling men to dive, or descend beneath the surface of water, to a greater depth, for a longer space of time, and with less exertion and danger, than is possible by the unassisted powers of the body. The fatal consequences of continued submersion have been described under ASPHYXIA [vol. ii., p. 490], and DROWNING [vol. ix., p. 157]; and from the facts there stated it is evident that about half a minute is the longest period during which most individuals can safely remain under water, without some provision for the supply of air for respiration. Experienced divers may remain under water much longer, though not without great and painful exertion; but the longest period of submersion, with a few extraordinary exceptions, does not exceed two minutes; a space of time too brief to allow the performance of any but the simplest operations beneath the surface of the water. The pearl-fishery affords the most prominent example of the employment of divers unassisted by apparatus for providing a supply of air. The mode of diving adopted, and the effects of protracted submersion upon the divers, are described under PEARL FISHERY [vol. xvii., p. 349]. Professor Beckmann alludes to the employment of divers in antient times to assist in raising anchors, in recovering goods from wrecks, or such as had been thrown overboard in times of danger, and in destroying the works and ships of the enemy in time of war, as well as in fishing for pearls; but some of the statements quoted by him are evidently much exaggerated, as they speak of divers remaining for hours under water. Six minutes is about the longest time of submersion of which any authentic account has appeared in modern times. [PEARL FISHERY.]

Dr. Halley, in a paper printed in No. 349 of the *Philosophical Transactions* (vol. xxix., p. 492), entitled 'The Art of Living under Water,' observes that the divers for sponges in the Archipelago were accustomed to take down in their mouths a piece of sponge soaked in oil, by which they were enabled to dive for a longer period than without it. As the bulk of the sponge must diminish the quantity of air which the diver could contain in his mouth, it does not appear probable that this practice could assist respiration. It has been more recently explained (*Ency. Brit.*, art 'Diving') as a means for assisting the diver to see when under water. In still water light is transmitted freely to a great depth; but when the surface is disturbed by waves, it is much obstructed. To ensure a good light, which may enable the diver to find the objects of his search without delay, it is stated that he ejects a little oil from the sponge; and this oil rising to the surface, and spreading upon it, calms the waves in a most remarkable manner, and occasions a brilliant light at the bottom.

In connection with diving by the unassisted powers of the body, allusion may be made to a curious and important fact related in the *Encyclopædia Britannica*, on the authority of Professor Faraday, to whom it was first noticed by a gentleman connected with the Asiatic Society. The lungs are, in their natural state, charged with a large quantity of impure air; this being a portion of the carbonic acid gas which is formed during respiration, but which, after each expiration, remains lodged in the involved passages of the pulmonary vessels. By breathing hard for a short time, as a person does after violent exercise, this impure air is expelled, and its place is supplied by pure atmospheric air, by which a person will be enabled to hold his breath much longer than without such precaution. The writer states that although he could only hold breath, after breathing in the ordinary way, for about three-quarters of a minute, and that with great difficulty, he felt no inconvenience, after making eight or ten forced respirations to clear the lungs, until the mouth and nostrils had been closed more than a minute and a half; and that he continued to hold breath to the end of the second minute. A knowledge of this fact may in many cases be of great importance, as it may enable a diver to remain under water at least twice as long as he otherwise could do. It is suggested that possibly the exertion of swimming may have the effect of occasioning the lungs to be cleared; so that persons accustomed to diving may unconsciously avail themselves of this preparatory measure.

Another important fact, related in the same work, indicates the advantage of breathing condensed air, and thereby obtaining a larger supply of oxygen in the same bulk than with air of the ordinary pressure. After one of the disastrous occurrences at the works of the Thames Tunnel, Mr. Brunel, the engineer, descended in a diving-bell to examine the breach made by the irruption of the river into the tunnel. The bell descended to the mouth of the opening, a depth of about thirty feet; but the breach was too narrow to allow it to go lower, in order that the shield and other works, which lay eight or ten feet deeper, might be examined from the bell. Brunel therefore took hold of a rope, and dived below the bell for the purpose. After he had remained under water about two minutes, his companion in the bell became alarmed, and gave a signal which occasioned Brunel to rise. On doing so he was surprised to find how much time had elapsed; and, on repeating the experiment, he ascertained that he could with ease remain fully two minutes under water; a circumstance accounted for by the condensation of the air in the bell, from which his lungs were supplied by the pressure of a column of water nearly thirty feet high, which would condense the air into little more than one half of its usual bulk.

Many plans were suggested for enabling persons to remain for a longer period under water than is possible by the natural powers of the body, long before extensive use was made of any of them. Beckmann alludes to a passage of Aristotle (problem xxxii. § 5), which has been supposed to intimate that in his time divers used a kind of kettle to enable them to continue longer under water; but this passage is variously rendered by different translators, and Beckmann appears to place little reliance upon it. He states that the oldest information we have respecting the use of the diving-bell in Europe is that of John Taisnier, quoted by P. Gaspar Schott. It occurs in the 'Technica Curiosa, sive Mirabilia Artis,' &c. of Schott, which was published at Nurnberg, in 1664, lib. vi., cap. ix., p. 393, and is taken from the 'Opusculum de Motu Celerrimo' of Taisnier, who says, 'Were the ignorant vulgar told that one could descend to the bottom of the Rhine, in the midst of the water, without wetting one's clothes or any part of one's body, and even carry a lighted candle to the bottom of the water, they would consider it as altogether ridiculous and impossible. This however I saw done at Toledo in Spain, in the year 1538, before the emperor Charles V. and almost ten thousand spectators. The experiment was made by two Greeks, who, taking a very large kettle suspended by ropes with the mouth downwards, fixed beams and planks in the middle of its concavity, upon which they placed themselves, together with a candle. The kettle was equipoised by means of lead fixed round its mouth, so that when let down towards the water no part of its circumference should touch the water sooner than another, else the water might easily have overcome the air included in it, and have converted it into moist vapour.'* Schott calls the machine described, 'Cacabus aquaticus,' or an 'aquatic kettle;' but he also describes an apparatus called 'Lorica aquatica,' or 'aquatic armour,' which would enable those who were covered with it to walk under water, and which he seems to prefer to the 'cacabus aquaticus' previously described.† This apparatus is represented in plate 31 of Schott's work, which shows a man walking into the water with a covering like a small diving-bell over his head, descending nearly to his feet.

In England, without noticing the supposed contrivance of a diving-machine by Roger Bacon, it is evident that the diving bell was known at an early period. It is mentioned by Lord Bacon (*Novum Organum*, lib. ii., § 50; and *Phænomena Universi*, p. 702) as a machine used to assist persons labouring under water upon wrecks, by affording a reservoir of air to which they might resort whenever they required to take breath.

Some curious information on submarine operations is given in the postscript to a little volume published at Edinburgh, in 1688, by George Sinclar, 'sometime Professor of Philosophy in the College of Glasgow,' entitled 'The Principles of Astronomy and Navigation.' The postscript contains an account of how 'to buoy up a ship of any burden, from the ground of the sea,' and states that among those who had, in this nation, attempted to recover property from wrecks by diving, was the late Marquis of Argyle, 'who, having obtained a patent from the king, of one of the Spanish Armado, which was sunk in the Isle of Mull, anno 1588, employed James Colquhoun, of Glasgow, a man of singular knowledge and skill in all mechanical arts and sciences.' 'This man,' he proceeds, 'not knowing the diving-bell, went down several times, the air from above being communicated to his lungs by a long pipe of leather. He only viewed and surveyed the ship, but I suppose buoyed nothing up.' Sinclar subsequently states that about 1664 the (then) late Lord Argyle employed an ingenious gentleman, the laird of Melgim, who went down with a diving-bell and got up three guns. A third and more successful trial was made, he says, several years after; and, still later, one Captain Smith was so confident of obtaining the gold supposed to be lost with the ship, that he would not admit a co-partner in the enterprise; which however came to nothing. Sinclar proposed to raise wrecks by the buoyancy of arks or boxes, open at the bottom, which were to be sunk full of water, and then filled with air either by sending down casks of air; by bellows and a long tube; or otherwise. He alludes to the occasional use of casks for the purpose of raising vessels, and explains why, when at a great depth, they are liable to be crushed by the pressure of the water, showing that, by allowing the water to enter by a hole in the lower part of the cask, it would so compress the air as to produce an equilibrium of pressure, and thereby preserve it from fracture.* About the time that the work above quoted was published, William Phips, who subsequently became governor of New England, attempted to raise treasure from the wreck of a Spanish ship sunk on the coast of Hispaniola. What was the precise character of his apparatus, we are not informed. His earliest experiments failed, but he was so confident of success, that he sought for assistance to enable him to prosecute his scheme. He at length obtained the patronage of the Duke of Albemarle, son of the celebrated Monk, and in 1687, after many difficulties, he succeeded in raising a large quantity of treasure, with which he returned to England; where he was honoured with knighthood for his enterprise. Most accounts state that the property he recovered amounted to 200,000*l.*; but in the 'Life of Sir William Phips,' published anonymously in 1697, but attributed to Increase Mather, it is stated as 300,000*l.* It is unnecessary to cite further instances of the use of diving apparatus, or to notice other early authors who have mentioned the diving-bell, excepting to observe that Beckmann alludes to engravings in editions of Vegetius on the art of war, published in 1511 and 1532, representing a diver with a cap, from which rises a long leathern pipe, terminating in an opening which floats upon the surface of the water; and to a figure published in a work on fortification, by Lorini, in 1607, which nearly resembles the modern diving-bell. Beckmann considers the insertion of the former as a proof that the person who drew them was not acquainted with the diving-bell, which he would otherwise have delineated. The machine described by Lorini consists of 'a square box bound round with iron, which is furnished with windows, and has a stool affixed to it for the diver.' Lorini, who was an Italian, does not lay claim to the invention of this apparatus.

Dr. Halley, in the paper before alluded to, in No. 349 of the 'Philosophical Transactions,' describes the defects of the diving-bell, as previously used, and suggests a remedy for them. This paper alone would be sufficient, although it does not enter into the early history of the machine, to contradict the erroneous statement which has been made to the effect that Halley was the inventor of the diving-bell.

In its simplest form the diving-bell is a strong heavy vessel of wood or metal, made perfectly air and water tight at the top and sides, but open at the bottom. If such a vessel be gradually lowered into the water, in a perfectly horizontal position, the air which it contains cannot escape, and therefore the vessel cannot become full of water. This may be readily illustrated by plunging a glass tumbler, in an inverted position, into a vessel of water, and placing a bit of cork, or any other substance which will float on the surface of the water, under the glass. If a bit of burning matter be laid upon the cork-float, it will be seen that it continues burning, although the glass and all that it contains be plunged far beneath the water; thereby proving that the upper part of the cavity of the glass is occupied by air, and not by water. In this experiment however it will be observed that the water does fill a small part of the cavity of the glass, and that it rises more into it when it is plunged to a considerable depth than when the rim is only just immersed beneath the surface. This is occasioned by the condensation of the air contained in the glass, which, being very elastic and compressible, is condensed into a smaller space by the pressure of the superincumbent water, when the glass is plunged to a considerable depth, than it will occupy under the ordinary pressure of the atmosphere. Where the diving-bell is used for descending to a very small depth, as the pressure of the water is small, it will not rise in the bell to a sufficient height to be inconvenient; but at the depth of thirty-three feet the pressure is so great as to compress the air into one-half its original volume, so that the bell will become half full of water; and at a greater depth the air will be still more compressed, and the water will rise proportionately higher in the bell. This condensation of the air does not materially interfere with respiration, provided the descent of the bell be very gradual, as the air then in-

* We quote from the translation in the English edition of Beckmann's 'History of Inventions,' by William Johnstone, second edition, 1814, vol. i., p. 184.

† His words are: 'Longè melior est alia illa, quam ex Francisco Kŏslero proponit *Daniel Schwenterus* in Deliciis Mathematicis,' Part 12, prop. 15.

* Beckmann quotes not from this work, but from one published at Rotterdam, in 1669, entitled 'G. Sinclari Ars nova et magna Gravitatis et Levitatis;' from which, he states, the description of the diving-bell was transcribed into Sturm's 'Collegium Curiosum.'

sinuates itself into the cavities of the body and balances the pressure from without. The principal effect of the increased pressure is a pain in the ears, occasioned by the circumstance that the Eustachian tube does not allow the condensed air immediately to find its way into the cavities of the ear, so that the pressure on the outside of the tympanum is, for a time, unbalanced by a corresponding pressure from within, and occasions a sensation like that of having quills forced into the ears. This continues until the pressure of the air in the mouth, which at first has a tendency to keep the aperture of the Eustachian tube closed, forces it open; an action which is accompanied by a noise like a slight explosion. The condensed air then enters the interior cavities of the ear, and, by restoring the equilibrium of pressure on each side of the tympanum, removes the pain; which will return, and be remedied in the same manner, if the bell should descend to a greater depth. But while the mere condensation of the air in the bell does not render it unfit for respiration, it would soon become so if no means were provided for renewing it from time to time, as it becomes vitiated by repeated respiration. The improvements invented by Dr. Halley provided a remedy for this inconvenience, and for that of the contracted space left free from water, when, by being at a great depth, the air is compressed into a small volume, by affording a convenient means of supplying the bell with any required quantity of fresh air, without raising it to the surface.

The bell used by Dr. Halley was of wood, in the form of a truncated cone, five feet in diameter at the bottom, and three feet at the top, and containing about sixty cubic feet. This was coated with lead, and so weighted about the lower part that it would sink while empty, and would always remain in its proper position; that is, with the large open end downwards, with its rim parallel with the horizon. In the top of the bell was a very strong glass window, and a cock, by opening which the foul air might be allowed to escape. About a yard below the mouth of the bell was suspended a stage, so weighted that it might hang steadily. The whole apparatus was suspended from a sprit attached to the mast of a ship, and provided with tackle by which the bell might be raised or lowered, and the sprit might be slung round so as either to carry the bell over the hull of the vessel, or to suspend it clear of her side. The apparatus for conveying air to the diving-bell consisted of two barrels, holding thirty-six gallons each, weighted with lead to make them sink readily. Each of these had an open bung-hole in the lower end, to allow water to enter during their descent, so as to condense the air in the manner described when explaining the principles of the diving-bell itself. There was also a hole in the upper end of each, to which was fitted an air-tight leathern hose, long enough to fall below the bottom of the barrel, and having its loose end so weighted that it would fall naturally into that position. These air-barrels were attached to tackle, by which, with the easy labour of two men, they might be made to rise and fall alternately, like two buckets in a well; and, by lines attached to the lower edge of the bell, they were so guided in their descent that the mouth of the hose always came directly to the hand of a man who stood upon the stage suspended from it. As the apertures of the hose were, during their descent, always below the level of the barrels, no air could escape from them; but when they were turned up by the attendant, so as to be above the level of the water in the barrels, the air rushed out with great force into the bell, the barrels becoming at the same time full of water. By sending down these air-barrels in rapid succession, the air in the barrel was kept in so pure a state that five persons remained in the bell, at a depth of nine or ten fathoms, for more than an hour and a half at a time, without injurious consequences; and Halley states that he could have remained there as long as he pleased, for anything that appeared to the contrary. In addition to this, by the copious supply of air admitted during the descent, the bell was kept constantly full of air, and the water was prevented from entering to any inconvenient extent. Halley observed that it was necessary to be let down gradually at first, and to pause at the depth of about twelve feet, to drive out, by the admission of a supply of air, the water which had entered the bell. When the diving-bell was arrived at the required depth, he let out, by the cock in the top of the bell, a quantity of hot impure air, equal to the quantity of fresh air admitted from the barrels. This foul air rushed up from the valve with such force as to cover the surface of the sea with a white foam. So perfect was the action of this apparatus, that Halley says he could, by removing the hanging stage, lay the bottom of the sea so far dry, within the circuit of the bell, as not to be over shoes thereon. When the sea was clear, and especially when the sun shone, sufficient light was transmitted to allow a person in the bell to write or read: and when the sea was troubled and thick, which occasioned the bell to be as dark as night, a candle was burnt in it. Halley sometimes sent up orders with the empty air-barrels, writing them with an iron pen on plates of lead. Having, by these ingenious contrivances, removed the principal difficulties attending the use of the diving-bell, Halley foresaw its extensive utility. He observes, 'This I take to be an invention applicable to various uses, such as fishing for pearl, diving for coral, sponges, and the like, in far greater depths than has hitherto been thought possible. Also for the fitting and plaining of the foundations of moles, bridges, &c. upon rocky bottoms; and for the cleaning and scrubbing of ships' bottoms when foul, in calm weather at sea.' 'But,' he adds, 'as I have no experience of these matters, I leave them to those that please to try.' To several of these purposes the diving-bell has, since the date of this paper (1717), been applied with great advantage.

In 1732 a communication was made to the 'Philosophical Transactions,' No. 444, vol. xxxix., p. 377, by Martin Triewald, 'Captain of Mechanics, and military architect to his Swedish majesty,' respecting an improvement of the diving-bell. He had the sole privilege of diving upon the coasts of the Baltic belonging to the king of Sweden; and he expresses his opinion, founded on much experience, that no apparatus but that on the principle of the 'campana urinatoria,' or diving-bell, could be safely used at great depths. His letter mentions a man, then sixty-three years old, who had followed the business of diving with the common diving-bell ever since he was twenty. Triewald's diving-bell was of copper, tinned inside, smaller than that of Dr. Halley, and managed by two men. A stage for the diver to stand upon was suspended at such a depth below it, that the man's head would be but little above the level of the water, where the air is cooler and fitter for respiration than in the upper part of the bell; and a spiral tube was attached to the inside of the bell, with a wide aperture at the bottom, and a flexible tube and mouth-piece at the top, so that, when the diver was up in the bell, he might inhale cool air from the lower part, exhaling the foul air by his nostrils. Dr. Halley's air-barrels are applicable to a bell of this construction. In lieu of windows of flat glass, Triewald used convex lenses to admit light to the bell.

In 1775 Mr. Spalding, of Edinburgh (who, according to the 'Annual Register,' vol. xix., p. 202, was a grocer), having some concern in a vessel which had been lost on the Fern Islands, was induced to make some experiments with Dr. Halley's diving-bell, with a view to recovering property from wrecks, and was thereby led to the invention of means for rendering it more safe and manageable. For these inventions he received, in 1776, a reward of twenty guineas from the Society for the Encouragement of Arts, Manufactures, and Commerce, in the first volume of whose 'Transactions' (pp. 220-238) they are fully described. Mr. Spalding's communication contains also a very interesting account of his experiments with Halley's diving-bell. The improved diving-bell contrived by Mr. Spalding was made so light, that, with the divers and the weights attached to the rim, it would not sink; the weight necessary to counteract its buoyancy being added in the form of a large balance-weight, suspended from its centre by a long rope, which was so mounted on pulleys that the divers could either draw the balance-weight up to the mouth of the bell or allow it to fall to a considerable depth below it. Thus, by letting the weight down to the bottom, the divers could, as it were, anchor the bell at any required level; or prevent its further descent if they perceived a rock or part of a wreck beneath it, which might otherwise overturn it. Also, by hauling in the rope while the weight was at the bottom, the persons in the bell might lower themselves at pleasure. Another improvement consisted in the addition of a horizontal partition near the top of the bell, which divided off a chamber that might, by suitable openings and valves, be filled either with water, or with air from the lower part of the bell; so as to alter the specific gravity of the whole machine, and thereby to cause it to ascend or descend at pleasure. The bell was supplied with air by an apparatus resembling that of Dr. Halley; and ropes, stretched across

the bell, were used instead of seats and platforms for standing on. By these arrangements the persons in the diving-bell were enabled, in case of accident, to raise themselves to the surface without any assistance from above; and it was rendered so perfectly manageable, that it might be removed to a considerable distance from the point at which it descended; its outward motion, and its return to the vessel for the purpose of being hauled up, being assisted by a long-boat, which carried the signal-lines and the tackle for working the air-barrels.

Though not in chronological order, it may be well here to allude to an improvement upon Spalding's apparatus, contrived by Mr. John Farey, junior, and described by him in the article 'Diving-Bell,' in Brewster's 'Edinburgh Encyclopædia.' He proposes to make the upper chamber of the diving-bell very strong and air-tight, without any openings for the admission of water. In the partition are fixed two forcing-pumps, by which a portion of air should be forced into the upper chamber, whenever, during a pause in the descent, the lower chamber, or the cavity of the bell, is replenished with air. By this means the upper chamber is made a reservoir of condensed air, from which the bell may be replenished with air when it is desired to increase its buoyancy by forcing out the water from the lower part. In like manner, the buoyancy of the bell can be at any time diminished by pumping some of the air from it into the upper chamber, whereby the water will be allowed to enter to a greater height; and, as this is effected without wasting the air, there is no danger of diminishing the buoyancy of the machine to a degree which would prevent it from rising, in case the suspending rope or chain should break. Mr. Farey recommends the form of the frustrum of an elliptic cone, for diving-bells intended for descending to wrecks; the dimensions being, for a bell to hold two persons, six feet by four at the base, three feet six inches by two feet six inches at the top, and six feet six inches high. He also suggests the use of a pressure-gauge in the bell, to show the divers what depth they have descended to; and of a compass to enable them to ascertain and give proper signals respecting the direction in which the bell should be moved. These signals are given by snatching a rope, which may be marked in the same manner as a deep-sea lead-line [SOUNDINGS, vol. xxii., p. 269], so that, after giving a signal to raise or lower the bell, the diver may, by hauling in a certain quantity of the signal-line, intimate the height to which the bell should be moved. Farey recommends that the men be attached by ropes to the bell, so that, in case of falling, they may not sink; and that, in case of being obliged to leave a wreck to which it is intended again to dive, the balance-weight may be left at the bottom, with a buoy attached to the upper end of its rope, so that the right point for descending may be found without difficulty.

The credit of having been the first to apply the diving-bell in aid of civil engineering operations is usually attributed to Smeaton, who used it in 1779 in repairing the foundations of Hexham Bridge. The Report in which he recommended its adoption is a very interesting document, as it affords a familiar explanation of the principle of the diving-bell. It is dated September 16, 1778; and is printed in the collected edition of his 'Reports,' vol. iii., p. 279. The bell used on this occasion was an oblong box of wood, four feet high, two wide, and three and a half long; and it was supplied with air by a pump fixed on the top. The river being shallow, the bell was not covered with water; but in 1788 the diving-bell was used in a much more important work, Ramsgate harbour, by the same engineer. Being here used at a considerable depth, an apparatus was employed for forcing in a supply of air through a flexible pipe, by means of a forcing-pump in a boat. The bell used in this work was of cast-iron, similar in form to that employed at Hexham, but four feet and a half high, four and a half long, and three wide. Its weight was fifty cwt., and the thickness was so adjusted that it would, without the addition of any weights, sink in the proper position. 'In levelling foundations under water by this machine, the surface of the water at the bottom of the bell formed a convenient and unerring level to work to; and in this, as well as in the subsequent operation of building, every necessary motion was given to the bell by the tackle by which it was suspended; signals being made from below by striking one, two, three, or more blows upon the side of the bell with a hammer.

Since the time of Smeaton the diving-bell has been frequently, and with great advantage, employed in submarine works; sometimes in situations in which it would have been impossible to construct a coffer-dam, or to perform the required operations by any other means. The diving-bells used in such works are usually formed on the model of that made for the works at Ramsgate harbour; but the mode of suspension differs according to circumstances. The bell may be suspended over the side or end of a vessel; through an opening in the centre of a barge; from frame-work resting upon two barges, placed parallel with each other, but at such a distance apart as to allow the bell to descend between them, or from a scaffolding supported by piles. In operations at the harbour of Howth, near Dublin, the late Mr. Rennie used a diving-bell suspended from a kind of railway scaffolding like that described under SCAFFOLDING [vol. xx., p. 497], as used in erecting large stone buildings; two carriages being used upon the scaffold, one to lower the stones, and the other to manage the bell. By the apparatus described as above, aided by ropes attached to the stones, and managed by the men in the bell, the submarine masonry could be executed with great facility. Of the use of this important machine in recovering property from wrecks, the operations upon that of the Royal George afford a familiar example. According to the 'Annual Register,' vol. lix., p. 42, this wreck was first surveyed by the diving-bell on the 24th of May, 1817. Smeaton's method of supplying air to the bell is that most commonly employed; but that of Halley may, in some cases, have the advantage.

In whatever way a diving-bell may be mounted, it is essential that it should descend very gradually, and that its descent should be perfectly under control. In 1838, Mr. Richard Jones, who had been placed in a very perilous situation by the failure of the crab by which a diving-bell in which he was descending was being lowered, was rewarded by the Society of Arts for a contrivance to prevent the occurrence of such an accident. His improved crab has a brake, regulated by the centrifugal motion of two balls, like the governor of a steam-engine; so that, while the crab revolves slowly, and therefore allows the bell to descend gradually, the brake may not be called into action; but if it should, from any cause, be overpowered by the weight of the bell, so as to run down with dangerous velocity, the separation of the balls should disengage the brake, and thereby stop the motion of the crab. The machine is described and represented in detail in vol. lii., p. 72, &c. of the Society's 'Transactions.'

Blasting is often required in submarine operations, and is commonly performed by joining lengths of tin tube together, until they reach from the charge of powder to a little above the surface of the water. These lengths of pipe are joined either by screws or by a cement of white lead, so as to be water-tight, and as the joining is effected, the bell gradually rises, so that the top of the pipe is always under it, until it reaches the surface, to prevent water from getting in. When all arrangements are completed, a person in a boat drops a piece of red-hot iron down the tube, and thus fires the charge. The recently-invented plan of blasting by electro-magnetism is far simpler and more certain than the above.

Many plans have been proposed for enabling a man to walk beneath the surface of water, or to dive in such a manner as to assist in the raising of anchors, or the recovery of property from wrecks, by means of waterproof coverings for the head and upper part of the body, or of strong vessels in which every part but the arms should be encased; a supply of air being either transmitted from above by a flexible pipe, or contained in the cavities of the protecting armour. Such apparatus may be conveniently used at small depths; but at any considerable depth they are both dangerous and inconvenient, because the strength necessary to enable them to bear the pressure of the water is incompatible with the flexibility essential to the free use of the limbs. Dr. Halley alludes, in his paper on the diving-bell, to some contrivances of this kind; and in a subsequent paper (*Phil. Trans.*, No. 368, vol. xxxi., p. 177) he describes an apparatus of his own invention, by which a man might leave the diving-bell, and walk about at the bottom of the sea; his head being covered by a heavy leaden cap like a small diving-bell, supplied with air by a flexible tube extending from the large bell. The diver was to coil this tube round his arm, and unwind it as he left the bell; and to use it as a clue to direct him to the bell in returning. This pipe was formed of leather soaked in oil and hot wax, and was held open by a spiral coil of brass-wire; its internal

diameter being about one-sixth of an inch. The pipe was then covered with several thicknesses of gut, and over all with leather. The modern invention of water-proof India-rubber cloth, which has been applied in various ways to diving-apparatus, affords great facilities for the manufacture of water-tight tubes for such a purpose. So long as the helmet was above the level of the water in the bell, it would be kept full of air; and in case of having to stoop below that level, as in getting out of or into the bell, the diver had only to close a valve, by which the air in the helmet was prevented from returning into the bell. The front of the helmet was glazed; and the diver, who was clothed in a thick woollen dress, fitting close to the body, to diminish the effect of the coldness of the water, was enabled to walk by means of a weighted girdle and weighted clogs. Aquatic armour, whether supplied with air from above, or carrying a store in its cavities, sufficient to last for the time the diver intends to remain submerged, has been brought so little into use, that it is needless to devote the space required for a minute description. The apparatus of M. Klingert, which was first described in a pamphlet published at Breslau, in 1798, has been fully explained in Tilloch's 'Philosophical Magazine' (vol. iii., pp. 59 and 171), and in many other English works; and a more recent contrivance of similar character has been exhibited at the Polytechnic Institution, London. In the 'Gentleman's Magazine' for September, 1749 (vol. xix., p. 412), will be found a notice of a curious diving-apparatus, consisting of a case enclosing the person, with the arms protruding in flexible sleeves, which is stated to have been contrived and used for many years by a person named John Lethbridge, who writes from Newton Abbot, near Exon, Devon, and states that he tried experiments as early as 1715. This was supplied with air by flexible pipes. A similar machine was contrived by Mr. Rowe, in 1753, which was to be lowered by tackle like a diving-bell.

One of the diving-machines contrived by Klingert was so arranged that it would rise or fall by the motion of a piston in a cylinder, in the lower part of the apparatus, by which the diver could vary the density of the air, and consequently the specific gravity of the machine, at pleasure. A very simple apparatus for enabling a person diving without a bell, or any of the machines above noticed, to effect the same object, has been recently invented by Mr. W. H. Thornthwaite of Hoxton. It is described in the fifty-second volume (p. 243) of the 'Transactions' of the Society of Arts, by whom Mr. Thornthwaite was rewarded for it in 1839; and it consists of a hollow belt of India-rubber cloth, to which is attached a small but strong copper vessel. Into this vessel air is to be forced by a condensing-syringe, until it has a pressure of thirty or forty atmospheres. The belt is then put on, in a collapsed state, so that it affords no buoyancy, and does not impede the descent of the diver; but when he desires to rise, he opens a valve, by which the condensed air escapes from the copper vessel into the belt. As it expands the belt, it affords sufficient buoyancy to raise the diver immediately to the surface.

An account of schemes for submarine descent would hardly be complete without some allusion to projects for submarine navigation, of which many have been suggested. An early instance is that of Cornelius Drebell, or Drebelle, who is said to have made a vessel to be rowed under water, which was tried in the Thames by order of James I., and carried twelve rowers, besides passengers. This vessel is alluded to by Robert Boyle, in his 'New Experiments Physico-Mechanicall, touching the Spring of the Air, and its effects,' &c., published at Oxford in 1660. Pages 363-5 of this curious work contain an account of Drebell's experiment, and state that he accounted his chief secret to be 'the composition of a liquid that would speedily restore to the troubled air such a proportion of vital parts as would make it again, for a good while, fit for respiration.' The composition of this liquid for enabling the same air to be used again and again, was never made public. Bishop Wilkins, who also favoured some other whimsical projects, devoted a whole chapter of his 'Mathematicall Magick,' which was published in 1648, to a dissertation 'Concerning the possibility of framing an Ark for Submarine Navigation.' In this work (book ii., chap. 5) he recites the difficulties of the scheme, but evidently considers them not insurmountable; and afterwards he enlarges upon its advantages, in privacy, security from pirates, storms, ice, &c., in naval warfare, philosophical experiments, discoveries, &c., and at length states that 'All kind of arts and manufactures may be exercised in this vessel. The observations made by it, may bee both written and (if need were) printed here likewise. Severall Colonies may thus inhabit, having their children born and bred up without the knowledge of land, who could not chuse but be amazed with strange conceits upon the discovery of this upper world.' The bishop adds, 'I am not able to judge what other advantages there may be suggested, or whether experiment would fully answer to these notionall conjectures.' In 1774 a projector named Day lost his life in an experimental descent in Plymouth Sound, with a vessel of about fifty tons burden, which he thought he could have caused to rise after a lapse of several hours; and this experiment, of which an account is given in the seventeenth volume of the 'Annual Register' (p. 245), led to the publication, in the following year, of a 'Philosophical Dissertation on the Diving Vessel projected by Mr. Day, and sunk in Plymouth Sound,' by N. D. Falck, M.D., which contains a representation and minute description of the vessel, an account of the ineffectual attempts to raise her, and much other curious matter. One of the most successful machines contrived for submarine navigation was that of Mr. Bushnell of Connecticut, which was projected in 1771, and completed in 1775. Bushnell's chief object appears to have been the introduction of submarine warfare. His vessel, which was propelled by screws, somewhat resembling those recently tried for steam-vessels, is described in the 'Transactions' of the American Philosophical Society, vol. iv., p. 303, whence the account was copied into 'Nicholson's Journal,' vol. iv., p. 229. The more recent projects of Fulton for the same purpose have been referred to in a previous volume. [FULTON, ROBERT, vol. xi., p. 13.] In the article 'Diving-Bell,' in the *Encyclopædia Metropolitana*, written by Mr. Babbage, a detailed plan is laid down for the construction of a vessel for submarine navigation. Among the suggestions there made are those of using oxygen, condensed in store-vessels, to replenish the air, and of absorbing the carbonic acid produced by respiration, either by cream of lime, or by a strong solution of ammonia.

SUBMARINE FORESTS. Under this term geologists class very numerous accumulations of vegetable matter, involving roots, stems, branches, leaves, and fruits of trees, rarely in the attitude of growth, sometimes in the condition of having fallen, and locally with the appearance of having been drifted from some distance, but all occurring on the margin of the sea, below the level of high-water, and extending not unfrequently much beyond the low-water line.

Subterranean Forests is another term for similar phenomena, not limited however to any particular level, nor to a close proximity with the sea. The circumstances as to level, and physical condition of the neighbouring regions, when these buried forests either grew on or were drifted to their present repositories, and the changes in these respects which may have since occurred, are extremely worthy of consideration.

If we take, as a mode of classifying these phenomena, the relative levels of the buried forests and the surface of the sea, we find a series of instances, beginning on high ground, and ending below the sea. On parts of the very high ground at the head of Glencoe, we see yet rooted in peaty soil the bases of enormous trunks of trees, while far around, and even in much lower levels, and warmer and more sheltered situations, large trees are altogether wanting. On the moderate elevations between Kirby Lonsdale and Kendal are small dried basins of antient lakes, in which portions of fir-trees abound; on the course of many rivers, in flat parts of valleys, and especially when they approach the sea, as at Ferrybridge on the Aire, and at Stockton on the Tees, vegetable accumulations, peaty plants, and lacustrine shells, hazel-[illegible] nuts, and large trees abound. In situations where the sea ceases to have power, along the sides of rivers, the accumulations of this nature are locally enormous, as over the large level of Hatfield Chase and Thorn Waste in Yorkshire, Sedgemoor in Somersetshire, and the fens of Huntingdon and Cambridge. Finally, on reaching the actual sea-shore, whether along the course of a great river, as the Humber or the Mersey, or on the bare coast, as in Lincolnshire, Yorkshire, Norfolk, and many parts of the coast of Great Britain, we find narrow or extensive deposits of like nature, both above high-water and below low-water mark. Generally in all these

situations, the trees, even though not now growing in the neighbourhood, are of sorts that belong to the same latitude and the same region. What might be the circumstances which encouraged their growth in antient times is not easy to be determined. Instead of supposing any elevation of land since the growth of trees in the high valleys about Glencoe, which, by raising the surface to a temperature too low, prevented their continued existence, it appears better to suppose that the duration of forests under some constant conditions is limited. It is only by mutual protection in some cases that trees rise to perfection. Arriving from this cause nearly at once to maturity, and passing by equal stages to decay, it may easily happen, in a limited area, that a whole forest of trees should perish and be followed by no successors. Such an occurrence might be accidentally caused by the alteration of the supply of water, the growth of peat, addition of sediments, and other causes of injury. Violent tempests might prostrate a forest, and affect the drainage of the country, and thus convert the area where the forest grew into a marsh, a peat-bog, a buried forest.

Suppositions of this nature have commonly been suggested by the phænomena observed in various parts of Europe. De Luc adopts such views regarding the buried pine-forest of Bornholm, which is covered by peat and surrounded by sand-hills. The trees lie prostrated from the circumference toward the centre, not by the force of inundations, but by the violence of winds. (*Hist. de la Terre*, v. 222.) A similar opinion has been entertained concerning some part of the extensive levels of Hatfield Chase in Yorkshire, where in places the trees appear as if prostrated in a particular direction. Moreover, in examining the deposits of this nature on the shores of the Frith of Tay, Dr. Fleming found the clay below the peat penetrated by numerous roots which are either carbonized or pyritized.

But there are other cases in which the accumulations of buried timber and peat may better be supposed to have been drifted. This appears to be the fact in the eastward prolongation of the great levels of Hatfield Chase along the æstuary of the Humber, and much below its level. De Luc supposes the same thing in regard to the peaty deposit of Rotterdam, which rests on silt, as that reposes on sand. He regards the whole as drifted by the river currents, and as accumulated below the river waters.

There are many examples of the occurrence in one deposit of sand, clay, peat, timber, lacustrine shells, and bones of quadrupeds. It is rather characteristic of such combinations that there is only one layer of peat with trees, that it lies upon the clay, and that in this clay are the lacustrine shells and the bones of quadrupeds. This general rule applies to numerous small deposits on the coasts of Yorkshire and Lincolnshire, including bones of deer, and to the larger area of the Irish peat, which yield the bones of the gigantic elk; and is exemplified in the American deposits which contain the mastodon. Beneath the whole of these deposits frequently lie the gravelly clays and sands, with boulders of distant rocks, commonly called 'Diluvium.' The shells are usually of existing species, the trees of existing kinds, but the quadrupeds (beaver and Irish elk for instance) often of races locally or universally extinct.

It has been thought necessary in some cases to appeal to a local change of the relative level of land and sea for an explanation of the submerged forests of the English and European coasts: sometimes this may be avoided by assuming in antient times a different condition of the tides; and sometimes it is unnecessary, because the trees may be supposed to have been transported. It should seldom be granted, because, in the very same district, the 'diluvium' with its marine shells may be thought to be a 'raised beach,' and the submarine forests to mark a real subsidence of the land. This is the case in Holderness.

The antiquity of these buried forests is often beyond the
inference, but in many inland districts the con-
trees is such as to have led observers to
re *cut down* or *burned down*. In Hatfield
runs., 1701) many of the trees were thus de-
were evidently worked by the woodman's
wood. Roman coins were gathered from

SUBMULTIPLE, an ALIQUOT PART.

SUBMYTILA'CEA, M. de Blainville's name for his sixth family of LAMELLIBRANCHIATA.

The following is his definition of the *Submytilacea*:—Mantle nearly as in the *Mytilacea*, that is to say, adherent, and slit throughout its lower part, with a distinct orifice for the anus and a commencement of a tube for respiration by means of a particular disposition of its posterior extremity, which is furnished with tentacular papillæ; a large fleshy abdominal mass for locomotion, without byssus at its base; two distinct muscular impressions.

Shell free, subnacreous, regular, equivalve; dorsal hinge lamellar, ligament external; two muscular impressions with the pallial impression which unites them not excavated backwards.

M. de Blainville remarks that this family are more or less inhabitants of mud, and are locomotive by means of their foot.

He divides them into two sections:—

1. The Limnoconchs (Limnoderma, Poli).

All these have an epidermis, are nacreous, and are inhabitants of fresh waters. [NAIADES.]

2.

Species without any evident epidermis, not nacreous, and more or less pectinated.

These are marine.

Under this section M. de Blainville arranges but one genus, *Cardita*.

Lamarck placed the genus *Cardita* in his family *Cardiacea*, between *Cardium* [CONCHACEA, vol. vii., p. 426] and *Cypricardia*. But M. Deshayes, in the last edition of the *Animaux sans Vertèbres*, well observes that this is not the true position of *Cardita*, as far as its approximation to *Cardium* is concerned, for the *Carditæ* have the lobes of the mantle disunited throughout their extent, whilst the other mollusks of the same family have these lobes united posteriorly and perforated with two apertures; and he observes that it will be right to follow the example of Cuvier and De Blainville, and to approximate the *Carditæ* to the *Unionidæ*, or fresh-water muscles. He remarks that Lamarck seems to believe that certain *Carditæ* have a byssus; but he adds that certain individuals checked in their growth, and so become irregular, have given rise to this opinion, which seems to him to be without foundation.

Generic Character.—*Animal* resembling that of the fresh-water muscles. [NAIADES.]

Shell very thick, solid, equivalve, often very inequilateral; umbones recurved forwards; hinge with two unequal oblique teeth, one short and cardinal, the other long, lamellar, bent, and placed much more backwards; ligament elongated, subexternal, and sunk into the shell; muscular impressions rather large and very distinct; pallial impression narrow.

M. de Blainville divides the genus into the following sections:—

A. Elongated species, a little notched or gaping at the inferior border; umbo nearly cephalic; ligament hidden. (The *Mytilicardia*.)

Examples, *Cardita crassicosta*, Adans., 'Seneg.,' pl. 15, f. 8; and *Cardita calyculata*, 'Malacol.,' pl. 69, fig. 1.

B. Oval species, with the inferior border nearly straight or a little convex, crenulated and completely closed. (The *Cardiocardita*.)

Example, *Cardita Ajar*. Adans., 'Seneg.,' pl. 16, f. 2.

C. Species nearly round or suborbicular, with the inferior border rounded, denticulated, and more and more equilateral; the two teeth shorter and more oblique. (Genus *Venericardia*, Lam.)

Example, *Venericardia imbricata*, 'Malacol.,' pl. 68, f. 3.

D. Elongated and very inequilateral species; the umbo nearly cephalic and recurved forwards; two short cardinal diverging teeth besides the lamellar teeth; ligament very long, little or not at all projecting; abdominal impression sometimes a little directed backwards. (Genus *Cypricardia*, Lam.)

M. Deshayes, in the last edition of Lamarck, observes

that the *Cypricardiæ* resemble the *Carditæ* in their form; but that, nevertheless, on a careful examination, one may perceive that they have more relationship to the *Cardia*: it is thus, he adds, that some species of the last genus lose the anterior lateral tooth; and others, instead of having the cardinal teeth *en croix*, have them nearly equal and diverging, as in the *Veneres*. If, says M. Deshayes, we unite the two modifications of *Cardia* in a single shell, we have a *Cypricardia*. On the other hand, the position of the muscular impressions, their extent, the pallial impression nearly simple or hardly sinuous posteriorly, and the great space which it leaves between itself and the border, lead M. Deshayes to suppose that the animal of *Cypricardia* has, as in *Cardium*, the lobes of the mantle united posteriorly and pierced in the commissure with two unequal apertures.

With regard to *Venericardia*, M. Deshayes (*loc. cit.*) is of opinion that it will be necessary to change the relationship of that genus, placed by Lamarck among the *Veneres*, and even to suppress it altogether, for the purpose of removing the species assembled under it to the genus *Cardita*. Many cogent reasons conducted M. Deshayes to this result. Poli, he remarks, has, in his great work, given figures of the animals of two species, one belonging to *Cardita*, the other to *Venericardia*. The resemblance of these animals in all essential characters proves satisfactorily that they appertain to the same genus, and this resemblance of the animals will be confirmed by that of the shells. We see, continues M. Deshayes, that Lamarck has comprised among his *Carditæ* elongated, transverse, very inequilateral shells, having at the hinge one or two very oblique teeth in the direction of the upper border. Doubtless if all the *Carditæ* were transverse, and the hinge presented some peculiar characters, it would have been reasonable enough to separate them, supposing the animals to be unknown; but this is not so, and Lamarck himself has arranged among the *Carditæ* rounded shells which have all the characters of *Venericardiæ*. In uniting all the species, living or fossil, of the two genera, and placing them in their most natural positions, a passage between them will be observed so insensible, says M. Deshayes, that it will be impossible to point out where *Venericardia* finishes and *Cardita* commences. When all the characters are examined, the same resemblance is observable as in the external forms. Nearly without exception, the *Venericardiæ* and *Carditæ* have longitudinal ribs, their shell is thick and solid, the lunule is small and much sunk, the hinge is more or less thick according to the species, and offers some modifications of small importance, according as the shell is rounded or transverse; these two teeth are oblique; and this obliquity is observable even in some species which are entirely transverse; but in the greater number of these last the anterior tooth becomes very small and perpendicular to the first: these differences are established by shades in passing from one species to the other. The pallial impression is always simple in its contour, and this important character is found in the *Venericardiæ* as well as in the *Carditæ*. It is necessary, M. Deshayes remarks, to remember here that in the *Conques* the pallial impression is never simple: posteriorly is seen a triangular inflexion, which announces that all the animals of that family are provided with two siphons posteriorly; the *Venericardiæ* and *Carditæ* have it not; the borders of the mantle are free throughout their extent, as in the *Naiades*. Up to this time naturalists have regarded as of great value the presence or absence of siphons, and the union or separation of the lobes of the mantle, and have advantageously employed these characters for the formation of families: if that of the *Conques*, to make it natural, ought not to contain any animals excepting those furnished with siphons posteriorly, and it is certain that such should be the rule, it becomes evident that *Venericardia* should be transported elsewhere; and as we have seen that it becomes fused as it were into *Cardita*, it ought to undergo the change of relationship necessary for that genus.

Habits of Cypricardia.—*Cypricardiæ* have been found on sands and reefs, but the depths do not appear to have been recorded.

Habits of Venericardia.—*Venericardia* has been found on mud and sands at depths varying from the surface to fifty fathoms.

Habits of Cardita.—*Cardita* has been taken on mud and sands, and sometimes attached to stones. Depths varying from the surface to thirteen fathoms.

M. Deshayes, in his Tables, makes the number of living species of *Venericardia* and *Cardita*, which he joins together, twenty-five: and he records *Carditæ Sulcata*, *Ajar*, *trapezia*, *squamosa*, *crassa*, and *intermedia*, as being found both living and fossil (tertiary). In the last edition of Lamarck, the only living species of *Venericardia* noticed is *Ven. australis*, from the seas of New Holland: of *Carditæ* twenty-one living species are recorded. To these must be added nine living species brought home from the coasts of Central America principally, by Mr. Cuming, and described by Mr. G. B. Sowerby and Mr. Broderip respectively in the 'Proceedings' of the Zoological Society of London, for 1832, and in Müller's 'Synopsis Testaceorum.'

Example, *Cardita calyculata*.

Description.—Shell oblong, white, painted with lunate brown spots; the ribs imbricato-squamous; the scales arched and incumbent.

a

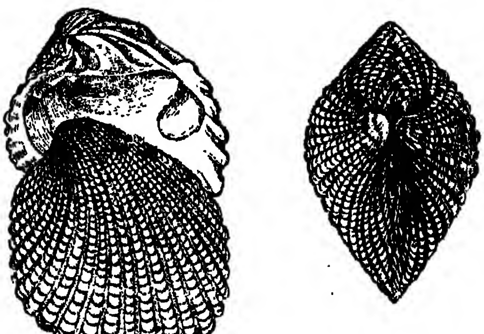
Cardita calyculata.

a, with the umbones turned towards the spectator sh… ; the hau…

Fossil Submytilacea.

With regard to the fresh-water division, see the article Naiades.

M. Deshayes, in his Tables, makes the number of fossil (tertiary) *Venericardiæ* and *Carditæ* fifty; the species found both living and fossil (tertiary) are noticed above. In the last edition of Lamarck the number of fossil *Venericardiæ* amounts to ten, and of *Carditæ* (fossil only) seven. Mr. Lea describes and figures four new species from the tertiary of Alabama. (*Contributions to Geology*.)



Venericardia (Cardita) imbricata.
Fossil from Grignon. A variety found at Courtagnon.

Dr. Mantell records *Venericardiæ planicosta* and *acuticosta* from the blue clay of Bracklesham, *Ven. Brongniarti* from the arenaceous limestone or sandstone of Bognor, a species from the chalk-marl, and a *Cardita?* from the firestone or upper green-sand. (*Organic Remains of the County of Sussex*.)

Professor Phillips records *Cardita similis* from the coralline and Bath oolite. (*Geology of Yorkshire*.)

Mr. Lonsdale notices a *Cardita* from the inferior oolite. (*Oolitic District of Bath*.)

Professor Sedgwick and Mr. Murchison mention a *Venericardia* from the Gosau deposit and its equivalents in the Alps; and a *Cardita* or *Venericardia* among the fossils of Lower Styria. (*Structure of the Eastern Alps*.)

Dr. Fitton records *Venericardia tenuicosta* from the gault (Kent, S. Wilts). (*Strata below the Chalk*.)

Mr. Murchison enumerates six species, all named, of *Cypricardia?* from the Silurian rocks—old red-sandstone (middle and lower beds only), upper Ludlow rock, Aymestry limestone, and lower Ludlow rock. (*Silurian System*.)

SUBORNATION OF PERJURY. [Perjury.]

SUBOSTRA'CEA, M. de Blainville's name for his second family of Lamellibranchiata.

Family Character.—Mantle open nearly throughout its circumference, retractile at all points, and not adherent; branchiæ not united throughout the median line, so as to

expose the abdomen, which is provided with the rudiment of a foot often canaliculated, with the rudiment of a byssus.

Shell of a close texture, subsymmetrical, always more or less auriculated, with a subcomplicated hinge; a single subcentral muscular impression, without any trace of the pallial ligula.

Genera.—*Spondylus, Hinnites, Pecten, Pedum, Lima.* [PECTINIDÆ; SPONDYLIDÆ.]

SUBPŒNA. [WITNESS.]

SUBPŒNA, WRIT OF. [PLEADING IN EQUITY; RICHARD II.]

SUBSALT. [SALTS.]

SUBSIDIARY. A quantity or symbol is so called when it is not essentially a part of a problem, but is introduced to help in the solution. The term is particularly applied to angles, since the trigonometrical tables give a great power over their management, which causes their frequent introduction, even in problems in which there is no question of angular quantity. For example, suppose it required to calculate $ax + b\sqrt{(1 - x^2)}$, where $a = \cdot 29164$, $b = 3\cdot 0018$, $x = \cdot 11316$. Assume $x = \cos\theta$, $a = r\cos\phi$, $b = r\sin\phi$, which gives θ from the tables, and ϕ and r from the tables, and from

$$\tan\phi = \frac{b}{a},\ r = \frac{a}{\cos\phi}.$$

The quantity to be calculated is

$$r\cos\phi\cos\theta + r\sin\phi\sin\theta, \text{ or } r\cos(\phi-\theta),$$

$$\text{or} \quad \frac{a\cos(\phi-\theta)}{\cos\phi},$$

and the final result is found from the tables in much less time than $ax + b\sqrt{(1-x^2)}$ could be calculated by ordinary means. There is of course no rule for the most convenient introduction of subsidiary angles: every case must be treated according to the circumstances it presents.

SUBSIDY, from *subsidium*, a Latin word signifying aid or assistance. 'Subsidies,' says Lord Coke, 'were antiently called auxilia, aides, granted by act of parliament upon need and necessity; as also for that originally and principally they were granted for the defence of the realm and the safe keeping of the seas,' &c. The word used in its general sense was applied to aids of every description; these were of two kinds, one perpetual, the other temporary. Those which were perpetual were the antient or grand customs, the new or petty customs, and the custom on broadcloth. The temporary included tonnage and poundage; a rate of four shillings in the pound on lands, and two shillings and eight pence on goods; and the fifteenths or tenths, &c. of moveable goods. The limited sense, which is also the more common sense, of the word subsidy, attaches only to the rate on lands and goods.

The grand customs were duties paid on the exportation of wool, sheepskins, and leather, at the rate of, for every sack of wool weighing thirty-six stone, half a mark, or six shillings and eightpence; for every three hundred sheepskins, half a mark; for a last of leather, a mark, or thirteen shillings and fourpence. The petty customs were payable by merchant strangers only, and consisted of an excess of one half over and above the grand customs payable by native merchants. The custom on broadcloth was first given to the king in the 21st year of Edw. III., to indemnify him for the loss he incurred in consequence of the practice, then beginning to prevail, of making up the wool into cloth in this country previous to its exportation. The rate of payment on broadcloths was fixed, in the 27 Edw. III., for every whole piece of cloth not ingrained, at fourpence; ingrained, at fivepence; if dyed scarlet, at sixpence. In addition to this was the alnager's fee, payable also to the crown, for measuring the cloth, at the rate of a halfpenny a cloth. There were also two species of customs payable on wines: one called butlerage, payable by foreigners importing wines, at the rate of two shillings for every tun of wine; the other, called prisage, payable by natives at the rate of, for every vessel importing ten tuns of wine, one tun; for every vessel importing twenty or upwards, two tuns; taken one tun from before, the other from behind the mast. This was compounded for by the payment of 20*s*. for each tun to which the king was entitled.

The origin of these customs seems uncertain; Lord Coke is very anxious to establish that they were in the first instance established by the common consent of the realm in parliament assembled. In support of this he cites Philip de Comines (lib. v., fo. 233): 'Reges Angliæ nihil tale, nis convocatis primis ordinibus, et assentiente populo, suscipiunt. Quæ consuetudo valde mihi laudanda videtur; interveniente enim populi voluntate et assensu crescit robur et potentia regum, et major est ipsorum auctoritas et feliciores progressus' (The kings of England take nothing of this kind unless the nobles are convoked and the people assent: which practice seems to me most laudable, for by the intervention of the free will and assent of the people the strength and power of kings becomes greater and their proceedings more fortunate). Comines however is speaking after various acts had passed restraining the king from taking customs without the assent of parliament. Coke also at great length inquires into the earliest parliamentary records in support of the same opinion. Every one however of those seems to show the existence of something payable as a custom anterior to any parliamentary grant. In the earliest statutes the customs are called custumae antiquae, and custumae ex antiquo.

Before and during Lord Coke's time, as well as immediately after it, the origin and nature of this kind of subsidy were most fully and ably discussed. To understand the subject it is necessary to advert to the sources of revenue possessed by the early Norman kings of England. These kings themselves held a large portion of the lands of the country. Some of these were occupied by villeins, which were taxable by their lord at his pleasure. Others were held by tenants in antient demesne, who originally were bound to perform services of an ignoble kind, such as manuring the lord's land, &c., which services were afterwards commuted for rent. The tenants in burgage, who held lands, &c. in royal cities and boroughs, were also taxable without their consent in parliament, but not, as was said, except upon extraordinary occasions. Lastly there were the tenants holding immediately of the king, who were bound to perform various feudal services. From these last tenants great profits arose to the king by escheats, relief, wardships, marriages, &c. The king also had a right to require contributions from the inhabitants of particular districts towards the expense of repairing bridges and the walls of towns, which contributions were called pontage and murage; and to grant by charter to any city the right to levy tolls upon all vendible things coming into the town. There were also other sources of revenue, the temporalities of vacant bishoprics, the forfeitures arising from felonies, &c. In the earlier periods these seem to have been considered sufficient to maintain the royal state, the courts of justice, &c., and also the ordinary expenses of any wars in which the king might be engaged. In the sixth year of Richard II., the commons petitioned the king that he would live upon his own revenues, and that wards, marriages, releases, escheats, forfeitures, and other profits of the crown might be kept to be spent upon the wars for the defence of the kingdom. In addition however to those duties of defending the kingdom by foreign wars, the king was bound to protect the merchants at sea from pirates, &c., and for this purpose a practice prevailed twice in the year 'to scour the narrow seas.' To defray the expenses of the royal navy, the king collected at the ports of his kingdom certain sums upon all merchandise imported or exported. These sums were called customs, a word which in itself indicates the earliness and uncertainty of their origin. 'To say the truth,' says Mr. Hakewell, in his able argument during the parliamentary discussion relative to Bate's case in the time of James I., 'all these things began, no man can say certainly when or how, but by a tacit consent of king and people and the long approbation of time beyond the memory of any man.' It is to be observed that Hakewell is arguing *against* the existence of a royal prerogative to lay fresh impositions. The right to collect some sum seems however to have existed from the earliest times, and the only limitation in amount seems to have been that the sum should be a reasonable one, regard being had to the purpose for which it was collected. In process of time however, the ordinary sources of the king's revenue being continually diminished by the alienation of crown lands, &c., while the expenses of the crown were increased, the kings imposed of their own authority such sums as varied from the original amount collected, and were complained of as unreasonable by the people. The earlier parliamentary history is full of remonstrances and petitions against grievous and unaccustomed impositions, maltolts (evil tolls), &c. There was an instance also of a petition by the merchants that they might pay no toll, but be allowed to protect their ships themselves. Ultimately the kings were driven by their necessities, the difficulties of the collection of irregular duties,

and the circumstances of their position, to have recourse to parliament to fix and authorise the sums to be collected as customs. The first statute on the subject occurs in the third year of the reign of Edward I., when the antient or grand customs were fixed at the sums already stated.

It is observable that in no instance was the right of the king to collect some duties disputed; all that is complained of is the excess and unreasonableness of the sum recently imposed. Many statutes occur on the subject, in which the king often—when the supply is needed, for instance, 23 Ed. I., as a provision against the French, who it is said intended altogether to wipe out (omnino delere) the English language—undertakes that the amount shall be properly applied, and that no aid shall be raised for the future except by consent of parliament. These promises, like the provisions of Magna Charta, which was renewed or confirmed thirty-one times, were generally broken, especially up to the end of the reign of Richard II. However, they were so often repeated, that at last they seem to have acquired some degree of validity, till they were again infringed in a few instances in the reigns of Elizabeth, Mary, and the Stuarts. In these later times however, such infringements were not passed over lightly. In the reign of James I. the question as to the right of the king to increase the customs upon merchandise, without assent of parliament, was raised on the occasion of his imposing five shillings per cwt. on currants. The court of exchequer decided that the king had such right, on the grounds, 1st, that his extraordinary and absolute prerogative was not bound by the statutes restaining him from increasing the customs without assent in parliament; 2nd, because the extra duty 'was not a burden to the commonwealth, but to delicate mouths.' This decision however raised great discussion in parliament, who pronounced it to be illegal. The writs for ship-money in the time of Charles I. created a similar ferment, and notwithstanding the petition of rights, the question cannot be said to have been entirely set at rest till up to the period of the Revolution.

The petty customs were originally founded on a bargain between the foreign merchants and king Edward I., by which they agreed to pay him the amount of them, in consideration of certain privileges granted them, and a release to them of all other prises and takings. Butlerage has the same origin, but is perhaps of an earlier date. Prisage is stated by Lord Coke himself to be due to the king by prescription, and the right of the king to it seems to have stood upon that alone; that right must have been one of inheritance, since by royal charters it was granted to the city of London and to the Cinque Ports for ever.

Tunnage and poundage was a duty varying in amount at different times from one shilling and sixpence to three shillings upon every tun of wine, and from sixpence to a shilling upon every pound of merchandise coming into the kingdom. The object in granting it was said to be, that the king might have money ready in case of a sudden occasion demanding it for the defence of the realm or the guarding of the sea. This kind of subsidy appears to have had a parliamentary origin. The earliest statute mentioned by Lord Coke as having granted it is 47 Ed. III. In the early instances it was granted for limited periods, and express provision was made that it should have intermission, and vary, lest the king should claim it as his duties. It was generally granted upon condition, or for a consideration expressed, as for the keeping and safeguard of the seas, &c., and in some instances the persons assigned to receive it showed particulars to prove that it had been properly expended about the salvation and defence of the kingdom. The duties of tunnage and poundage were granted to Henry V. for his life, with a proviso that it should not be drawn into a precedent for the future. However, notwithstanding the proviso, it was never afterwards granted to any king for a less period. These duties were farmed while Lord Coke was commissioner of the treasury, for 160,000*l.* a year. In the course of the argument in the case of ship-money in 13 Charles I., the king's duties are said to amount to 300,000*l.* This probably was the aggregate of the customs and tunnage and prisage.

Subsidy in its more usual and limited sense consisted of a rate of 4*s.* in the pound on lands, and 2*s.* 8*d.* on goods, and double upon the goods of aliens. The taxes called tenths, fifteenths, were the tenth or fifteenth part of the value of moveable goods. Other portions, such as the fifth, eighth, eleventh part, were sometimes, but rarely, also levied. These taxes seem to have had a parliamentary origin. There are no appearances of the king ever having attempted to collect them as of right. Henry III. received a fifteenth in return for granting Magna Charta and the Charta de Foresta. In the earlier periods never more than one subsidy and two fifteenths were granted. About the time of the expectation of the Armada (31 Eliz.), a double subsidy and four fifteenths were granted. The then chancellor of the exchequer, Sir Walter Mildmay, when moving for it, said, 'his heart did quake to move it, not knowing the inconvenience that should grow upon it.' The inconvenience did grow very fast, for treble and quadruple subsidies and six fifteenths were granted in the same reign. These grants seem to have been at intervals of about four years at that period. Subsidies and fifteenths were originally assessed upon each individual, but subsequently to the 8 Edward III., when a taxation was made upon all the towns, cities, and boroughs, by commissioners, the fifteenth became a sum certain, being the fifteenth part of their then existing value. After the fifteenth was granted by parliament, the inhabitants rated themselves. The subsidy, never having been thus fixed, continued uncertain, and was levied upon each person in respect of his lands and goods. But it appears that a person paid only in the county in which he lived, even though he possessed property in other counties. And, as Hume observes, probably where a man's property increased he paid no more, though where it was diminished he paid less. Certain it is that the subsidy continually decreased in amount. In the eighth year of the reign of Elizabeth it amounted to 120,000*l.*, in the 40th to 78,000*l.* only. Lord Coke estimates a subsidy (probably in the reign of James I. or Charles I.) at 70,000*l.*; the subsidy raised by the clergy, which was distinct from that of the laity, at 20,000*l.*; a fifteenth at about 29,000*l.* Eventually the subsidy was abolished, and a land tax substituted for it.

(2 *Inst.*; 4 *Inst*; 'Bate's Case,' &c., 2 *State Trials*, 371, ed. 1809; 'The Case of Ship Money,' 3 *State Trials*, 826, ed. 1809; Venn's *Abrt.*, tit. 'Prerogative;' Comyn's *Dig.*, tit. 'Parliament,' 'Prerogative.') [CUSTOMS.]

SUBSTANCE. In general usage Substance means a solid. In philosophical speculations it has undergone the fate of most general terms, and has been tortured into all possible shades of meaning. In physical speculations it has usually been taken as an equivalent to matter; but in metaphysical speculations its meaning, as sanctioned by the highest authorities, has remained true to its etymon (*substans*, that which *stands under* phenomena). This meaning will be rendered intelligible by the notion of some Hindu philosophers, who supposed the world to rest on the back of an elephant, and that the elephant stood on the back of a tortoise; what supported the tortoise, they omitted to explain. In adopting their theory, we may add that *that* which the tortoise stood upon was substance.

As we know that all phenomena must depend upon noumena, of which they are only the manifestation; or, to use the language of the schoolmen, as all accidents must be accidents of *something*, and must depend on that something for their existence, so in pushing our analysis to its limit, we must finally arrive at a point to which we can give no antecedent, which we are forced to assume as final, and as standing under or supporting the whole, and this we call Substance. It is the fundamental fact of all existence. We can never know it, for we know only phenomena, which are its appearances. We can never conceive it, for the first attempt to conceive it brings it within the sphere of our ideas, which are only those of phenomena. We can never imagine it, but we are compelled to assume it. It is to us a logical fact, not a noumenal one. Necessary as the basis of all speculation, as the 'point' in mathematics, but, like the point, for ever a mere logical distinction. It is needful for all men to know that this substance is, with respect to the mind, a merely logical distinction from its attributes; and it is needful also to know that as the mind can never transcend the sphere of its action, and consequently never know more than the attributes, all that it can predicate of substance must be false, for substance is to it a mere negation; if it would affirm anything of substance, it must inevitably affirm it by its attributes, which it alone can know positively.

It is from inattention to this latter fact that metaphysicians have blundered and misunderstood each other so constantly. You cannot conceive a point which has neither length nor breadth; you must assume it. You cannot

conceive substance shorn of its attributes, because those attributes are the sole staple of your conceptions; but you must assume it. Analyse as you will, you can never get beyond a vague and negative conception of a certain substratum, which, whenever you attempt to realise it, you must invest with attributes. Glass is a substance, at least is called so in common language. Analyse it, and you find that it is no substance—that it is merely the co-existence of flint and alkali. Your substance then has vanished with the analysis. It was found to be flint *and* alkali, nothing more; no distinct element, no *substratum* was discovered. Where then was your glass substance? The glass was a mere mode of existence of two particles of flint and alkali; it was in itself nothing, it had no existence apart from those particles, it had no *substratum*. Analyse the flint in the same way, and you will find the flint to be in itself no substance, but a mode of existence of some other particles. And yet the mind refuses to admit that this analysis could be so continued ad infinitum, thus reducing everything to mere phenomena; it is impelled to stop somewhere, and to ask, 'attributes of what?' and there where it stops it recognises substance. Hence Spinoza's definition of substance being existence itself.

Fichte, the most scientific expositor of idealism, has denied all substance except that of the Ego, and he says, 'Attributes synthetically united give substance, and substance analysed gives but attributes; a continued substratum, a supporter of attributes is an impossible conception.' (*Wissenschaftslehre*, p. 145.) Granted an impossible conception, but not therefore an impossible fact. Fichte assumes that the subjective conception—the idea—is the complete correlation and adequate comprehension of the whole objective fact; and if this point be admitted, his system is irrefutable, for attributes being obviously mental conditions, and as beyond them we are conscious of nothing, so nothing but what they affirm can exist. Interrogate consciousness, and you will get no answer that will apply to a substance. It knows only attributes. Matter is extended, coloured, and of a certain weight. Yet philosophy has long established that weight and colour are purely mental conditions—are effects produced by matter on the sensorium, not qualities of matter in themselves; and Kant has irrefragably shown extension to be the form imprinted on all objects by our minds; and even disputing this, there is no dispute that extension *quâ* extension is not matter, and that colour *quâ* colour is not matter, but that matter is *something* extended and coloured. No, replies Fichte, it is but the synthesis of these attributes, as glass was the synthesis of flint and alkali; and on the Ideal theory, there can be no question of his being correct.

If we dissent from these conclusions, and maintain that there is substance apart from its attributes (though we insist on this distinction being purely logical), it is because the Idealists have not proved the fundamental position on which all such speculation rests, namely, the truth of the correlation between the conception and the object, so that the one should be taken as the entire expression of the other.

In our analysis of substance it is impossible to get beyond attributes; and therefore, subjectively speaking, substance is nothing more than the synthesis of attributes: but does this entitle us to assume that it is equally the case objectively? Not until the subject has been proved to be the complete expression of the object.

But the truth is, attributes themselves are but the conditions excited in us by objects. The Ego acted on by the non-Ego undergoes certain affections: these mental affections are variously extension, colour, weight, hardness, &c., and these are all the effects of the action of the non-Ego upon the Ego, and as a consequence these are all we know, and all we know of the non-Ego. To call substance therefore the synthesis of attributes, is to say that in the synthesis of our mental affections is contained all that *constitutes* the non-Ego, instead of saying that in the synthesis of our mental affections is contained all we can positively *know* of the non-Ego; it is saying that we include all existence, and that fround our conceptions nothing exists; it is taking the hu-paymaind as the measure of the universe.
titled. maintain therefore, that inasmuch as what we call
Thutes are not vague abstractions, but positive effects of is vier acting on the sensory (and we assume the existence stamatter because Idealism has failed in disproving it); so parb must be substance or cause to produce those effects; Com lthough we can only know these effects and *by* these effects, yet we are necessitated to assume an inconceivable cause or substance. We do not know this substance: we only know what it excites in us, as a man in the dark receiving a blow from a bludgeon knows only his individual sensation received from that unknown something; it may be a stick, the butt-end of a gun, or a hammer: he knows nothing of what its nature may be; all he knows is what sensations it excites in him.

The stronghold of Idealism is consciousness. In consciousness there is nothing but transformations of itself—no substance, no external world is given; it knows, it feels, it is conscious of nothing but itself. But consciousness is equally the stronghold of Realism; for we are as conscious that what we call substance, or the world, is not ourselves, and does not depend upon us, and is a distinct existence, as we are of our own existence. Hence the universality of the belief of an external world—hence the impossibility of the Idealists' conceiving for an instant the non-existence of substance.

In conclusion we may observe, that substance is the unknown, unknowable substratum on which rests all that we experience of the external world: it is the hidden noumenon whose manifestations as represented in perception we call matter and the phenomena of matter, and of which every positive predicate must necessarily be false, and consequently all inquiry into its nature baseless.

SUBSTITUTION, a very common algebraical process, being, as its name imports, the substituting for any quantity another which is equal to it.

A method of approximation, which is frequently used and of great importance, has obtained the name of *successive substitution*. Let any equation be reduced to the form

$$x = a + e\phi x,$$

where e is less than unity, and ϕx a function of x. If we make $x=a$, the error thereby committed is less than ϕx, being $e\phi x$, in which e is less than unity. Take this value $x=a$, and substitute it on the second side, giving $x=a+e\phi a$: this value is nearer than the last in most cases, for it should be

$$x = a + e\phi\,(a + e\phi x)$$
$$= a + e\phi a + e^2\phi' a.\ \phi x \text{ nearly,}$$

where $\phi' a$ is the differential coefficient of ϕa. The last error was $e\phi x$, and the present error is less, if $e\phi' a$ be less than unity. Generally, if for x we write $a+p$, and if p be erroneous by a quantity of the order e^n, we shall have, by one more substitution,

$$x = a + e\phi\,(a+p).$$

Now the error of $\phi\,(a+p)$ will be of the order e^n, and that of $e\phi\,(a+p)$ of the order e^{n+1}. There is then a continual approximation to the value of x.

Beginning with $x=a+e\phi a$, in which the error is of the order e^2, we have

$$x = a + e\phi\,(a + e\phi a),$$

in which the error is of the third order. Rejecting terms of the third order, we have

$$x = a + e\phi a + e^2\phi a\,\phi' a.$$

Substitute this again, and we have

$$x = a + e\phi\,\{a + e\phi a + e^2\phi a\,\phi' a\},$$

in which the error is of the fourth order. Rejecting terms of the fourth order,

$$x = a + e\phi a + e^2\phi a\,\phi' a + e^3\left\{ (\phi' a)^2\phi a + \frac{\phi'' a}{2}(\phi a)^2 \right\}$$

and so on: the developments being made by TAYLOR'S THEOREM. This would lead in effect to the celebrated theorem of Lagrange: but the actual method of substitution is sometimes preferable.

SUBTANGENT, SUBNORMAL. [TANGENT.]

SUBTENSE, means any line, angle, &c. opposite to or *subtending* a line or angle spoken of. Thus the chord of a circle is the subtense of the arc and of the angle at the centre. The term is now not much used.

SUBTERRANEAN FORESTS. [SUBMARINE FORESTS.]

SUBTRACTION, SUBTRAHEND, MINUEND. The process of subtraction is the removal of a part equal to the less from the greater. The quantity to be diminished (*minuendum*) was called the *minuend*; the quantity to be withdrawn (*subtrahendum*) the *subtrahend*; and the remaining part the *remainder*. The terms subtrahend and minuend are almost out of use, though often very convenient.

The operation of subtraction is often described in a way which might be practised, but is not; and the explanation of the possible mode applied to the actual mode makes confusion. It is obvious enough that if parts of A be subtracted severally from greater parts of B, the remainders put together make up the whole remainder. Thus 24 can easily be taken from 76, for 7 tens exceeds 2 tens by 5 tens, and 6 exceeds 4 by 2, so that 52 is the remainder required. But when we come to take 48 from 93, the preceding mode of partition is useless. To remedy this it is proposed in the explanation to *borrow* one of the nine tens in 94, and to put it on to the 4: then 8 from 13 leaves 5. Now take the four tens of 48, and subtract from the *remaining* 8 tens of 93, and 4 tens are left: the answer then is 45. The process would be as follows:—

93	8 from 3, impossible: borrow a ten from 90; 8 from
48	13 leaves 5. Take 4 tens from the remaining 8
—	tens, one of the nine tens having been borrowed,
45	and 4 tens remain.

This process is actually used on the Continent, but with us, as all the world knows, there is a different process, as follows:—

93	8 from 3, impossible: take 8 from 13, and 5 remains.
48	*Carry** one to 4, giving 5, and subtract 5 tens from
—	9 tens, giving 4 tens.
45	

There is quite a different principle in this process, which is as follows:—If two numbers be equally increased or equally diminished, the difference remains the same. Having arbitrarily increased the three in the upper line by ten, the lower line must be somewhere or other increased by ten, in order to keep the difference (which is all that is wanted) unaltered.

The object in view is attained by increasing the upper line by ten *units*, and the lower line by one *ten*.

We are inclined to think that in the actual performance of subtraction it would be better than the mode usually employed, if we added in thought to the lower to make the higher, instead of passing from the higher to the lower by mental subtraction. Thus the details of the following question are written down, the words in Italics being made emphatic, and the figures written down at the moment they are repeated or thought of:—

```
4794236
 887349
-------
3906887
```

Nine *and seven* are sixteen (some persons would here take the trouble to say, carry one, one and four are five: but in this method, if the last-named word be ten or more, it is a direction to increase the next figure by one). Five *and eight* are thirteen: four *and eight* are twelve: eight *and six* are fourteen: nine *and nought*† are nine: eight *and nine* are seventeen: one *and three* are four.

This mode would render easy the compendious manner in which the operation of division, extraction of the square root, &c. are performed by some of the continental nations, in which the multiplication and the subtraction by which it is followed are performed at one step: thus—

```
12439729 ) 43874924183 ( 3527
            65557371
             33587268
              87078103
              00000000
```

The first step is to multiply 12439729 by 3, and to take the result from 43874924; the subtraction is performed by passing to the proper unit in the same decad or that next above, and carrying the tens' figure of the decad last employed. The proceeds of the multiplication table are put down without statement, and the computer should learn to remember products without the necessity of repeating '6 times 5 is 30,' '7 times 7 is 49,' &c.

27 *and seven* are 34: 6 and 3 are 9 *and three* are 12: 21 and 1 are 22 *and seven* are 29: 27 and 2 are 29 *and five* are 34: 9 and 3 are 12 *and five* are 17: 12 and 1 are 13 *and five* are 18: 6 and 1 are 7 *and six* are 13: 3 and 1 are 4 *and nought* are 4. The remaining steps are done in the same way. A person not used to this method will hardly believe at first how easily it is acquired, and how much trouble it saves. Those foreigners who are brought up in it find our method perplexing, and liable to lead to error, and greatly prefer their own—we think, with reason.

* The student may well ask *from where?* The term 'carry' is not the proper one.

† Beginners in arithmetic (and older persons too) frequently think this word is *ought*; but *ought* is anything, and *nought* is nothing.

SUBULICORNES (Latreille), a section of Neuropterous insects containing the dragon-flies (*Libellula*, Linn.) and the Ephemeræ. The larvæ of these insects are carnivorous, and live in the water, respiring by means of appendages situated on the sides or extremity of the body; the pupæ also live in the water, but leave that element to undergo the final transformation. In the perfect insect the wings are always reticulated, and when at rest are in some species horizontal, in others vertical; the compound eyes are very large and prominent; and the ocelli, or simple eyes, are two or three in number; the mandibles and maxillæ are covered by the labrum and labium; the antennæ are short, slender, and subulate.

The dragon-flies (*Libellulidæ*) have the four wings of equal length, the tarsi three-jointed, the antennæ very small and resembling minute bristles, the eyes extremely large, and generally approximated above; the fore part of the head, or what might be termed the face, has an inflated appearance; the legs are rather small, and the abdomen is elongated, sometimes cylindrical, and sometimes depressed, and terminated by membranous appendages. The larvæ and pupæ, both of which are active, nearly resemble the perfect insect in general form, and are remarkable for the great development of the labial apparatus, which is elongated and dilated at the extremity, and covers the fore part of the head like a mask.

The *Libellulæ* are divided into three genera by Fabricius. Those species which have the wings extended horizontally when at rest, the head almost globular, the eyes very large and meeting on the vertex, an elevation in front and close to the eyes, and the abdomen depressed, form the genus *Libellula* as restricted by that author.

The second genus (*Æshna*, Fab.) is chiefly distinguished by the cylindrical form of the abdomen and its greater proportionate length. The wings are as in *Libellula*, and the head is of the same globular form.

In the third genus (*Agrion*, Fab.) the wings when at rest are elevated perpendicularly; the head is transverse, and the eyes are widely separated. Examples of each of these genera are found in this country.

The second division of the *Subulicornes*, or the family *Ephemeridæ*, is distinguished from the *Libellulidæ* by the comparative softness of the parts of the mouth, they being of a membranous character in the insects of the present family, and the parts less defined; the tarsi are five-jointed; the inferior wings are much smaller than the upper, and in some are absent; the abdomen is terminated by two or three long and hair-like appendages. They form the genus *Ephemera*, according to Linnæus, and were so called on account of their short term of life, that is, in the imago or perfect state.

The Ephemeræ, or May-flies, Latreille states, usually appear at sunset, in fine weather in summer and autumn, on the banks of rivers, lakes, &c., and sometimes in such remarkable numbers, that after their death the surface of the ground is completely covered with them, and in certain districts on the Continent they have been collected in cart-loads for manure.

These insects collect together in great numbers in the air, and fly in an undulating manner, constantly ascending and descending, and have a very beautiful appearance. The males are distinguished from the females by the abdomen being furnished with two articulated hooks at the extremity, and apparently the anterior legs and the terminal filaments of the abdomen are larger in this sex; the eyes are also larger. In some there are four compound eyes, two of which are elevated and larger than the others.

The female insect deposits her eggs in the water, and these are collected together in a mass, after which it ...ses which it ...ey the duration of life in the perfect state b...arkable fact, that both sexes. When however we trace ...ost variable forms, transformations, we find their existence ...formation in all the one, for in the larva and pupa state som... the young *Bran*-two or three years. During this time ...nce it is even im-hidden, at least in the day-time, in th... of *Cyclops*. stones; sometimes in horizontal holes ...subclass divides rivers.

SUCCESSIVE SUBSTITUTION. [SUBSTITUTION.]

SUCCINAMIDE. When dry succinic acid is acted upon by ammonia, water is given off with the evolution of heat, and a fusible crystallizable *amide* is formed, soluble in water and in alcohol.

According to D'Arcet, it consists of nearly—

Eight equivalents of carbon . .	48
Five equivalents of hydrogen . .	5
Four equivalents of oxygen . .	32
One equivalent of azote . .	14
	—
Equivalent . .	99

When crystallized, it contains two equivalents of water 18; its equivalent is then 117.

SUCCI'NEA, M. Draparnaud's name for a genus of pulmoniferous gastropods belonging to the *Colimacea* of Lamarck and the *Limacinea* of De Blainville. It is the subgenus *Cochlohydra* of Férussac.

The shell is ovate, rather elongated, with a large, entire, longitudinal aperture, and a short spire; the outer lip is thin and continuous with the delicate sharp-edged columella; the inner lip is spread over a part of the body-whorl. The shell may be distinguished from that of *Limnæa* [LIMNEANS, vol. xiii., p. 501] by its not having a fold or plait on the columella.

Cuvier, who places the genus between *Chondrus* and *Clausilia*, remarks that the animal cannot withdraw itself into the shell entirely, and that it may be regarded almost as a TESTACELLA with a large shell. It has, he remarks, the lower tentacula very small, and lives on the herbage and plants on the brinks of streams, whence it has been considered as amphibious. [HELICIDÆ, vol. xii., p. 106.]

The most familiar species is *Succinea amphibia, Helix putris* of Linnæus, whose specific name has the priority, common in moist places, on the banks of fresh waters.

SUCCINIC ACID is obtained from amber by the application of heat, when the acid sublimes, mixed with much empyreumatic oil and some acetic acid; it is stated that a greater product is obtained when the amber is mixed before sublimation with one-twelfth of its weight of sulphuric acid diluted with an equal weight of water. The acid is purified by treating it with dilute nitric acid, by which, unlike most acids similarly constituted, it is not altered or decomposed; by evaporating the solution, crystals of the acid are procured, which possess the following properties:—they are colourless, inodorous, are acid and somewhat acrid in taste, and sublime without decomposition when heated. These crystals are hydrated, and are soluble in two parts of boiling and five parts of cold water, and they dissolve also in alcohol and æther; when heated to 356°, the crystals lose half their water. This acid consists very nearly of—

Two equivalents of carbon . .	24
Two equivalents of hydrogen .	2
Three equivalents of oxygen .	24
	—
Equivalent . .	50

The crystals contain one equivalent of water, making its equivalent number 59. Succinic acid was formerly employed in medicine under the name of salt of amber; it is now chiefly used in combination with ammonia, forming succinate of ammonia in chemical investigations, especially for precipitating iron from solution.

Succinic acid combines readily with the alkalis, earths, and metallic oxides; several of its compounds with the latter are crystallizable, but are not applied to any particular purpose.

SU'CCINUM is a bituminous substance of a peculiar kind, the natural history and chemistry of which have been already detailed. [AMBER, vol. i., 421.] It is not now used in the crude state in medicine, but is employed to yield the oleum succini, or oil of amber. This is procured by the destructive distillation of amber, which is put into a glass, copper, or iron retort, fitted with a glass alembic properly luted. A gentle heat is applied by means of a sand-bath, [illegible] which the amber is melted and a little volatile oil passes [illegible] the amber swells greatly, and the distilla[illegible]lly. By this process three very distinct [illegible]d, viz. impure succinic acid, which ad[illegible] of the retort; an acid liquid (called [illegible]cini), in which succinic and acetic acids [illegible] empyreumatic oil; and, lastly, the vola[illegible] which is to be separated from the acid [illegible] pouring off. What remains in the retort is *colophony* of amber, which is used to make varnish. The volatile oil thus obtained is impure, containing various pyrogenous ingredients, and requires repeated distillations to purify it. If in the third or fourth of these the process be interrupted when about two-thirds only of the oil has passed into the receiver, there is obtained a volatile oil of a light yellow colour, a peculiar bituminous odour, and of the specific gravity 0·880. If the distillation be continued too long, an empyreumatic oil is evolved, which gives to the other a coffee-brown hue; and this is the general appearance of rectified oil of amber. By some writers freshly prepared charcoal is directed to be put into the retort when the impure oil is to be distilled, but this is very improper, as by its means the pyrogenous principles, which it is the object of the rectification to separate, are very abundantly generated. The purest oil has a sharp burning taste, an acid re-action, and on exposure to the air becomes brown and inspissated.

Volatile oil of amber probably contains a large portion of creasote, as may be inferred from the analogous action of nitric acid on it and on creasote. One part of rectified oil of amber, and three parts of moderately strong nitric acid, form a magma, which has the odour of musk, and is called *artificial musk*. Rectified oil of amber is stimulating, antispasmodic, and rubefacient. It is now little given internally, except in combination with ammonia, in the celebrated *eau-de-luce*, for which the *tinctura ammonia composita* of the present Pharmacopœia is a substitute. This is to be applied to the nostrils in fainting, hysteria, and epilepsy, or a very few drops diluted with water may be taken internally. Oil of amber is beneficially rubbed along the spine in the later stages of hooping-cough. Dr. A. T. Thomson says that one ounce of rectified oil of amber, with half an ounce of tincture of opium, forms a good embrocation in tic-doloureux; its disagreeable odour is an obstacle to its employment when the face is the seat of the disease; but it proves a most valuable application when the limbs begin to lose their tone and swell in advanced life.

SUCCORY, commonly called Chicory, or Wild Endive, the Cichorium Intybus of botanists, which belongs to the tribe Cichoraceæ and natural family Compositæ. De Theis derives the name from *chikouryeh*, stated by Forskäl to be the Arabic name. The name Endivia seems to be derived from another Arabic name, *hindibeh*. The genus Cichorium consists of only a few species found in the temperate parts of Asia, the Mediterranean region, and in Europe. It has a double involucre, of which the exterior is 5- and the interior 8-leaved, with the leaflets united at the base; pappus crown-like, formed of many paleæ, shorter than the achenium. Receptacle naked or pitted. Flowers blue. *C. Intybus*, found in uncultivated places, dry pastures, and roadsides in Europe, has two or more heads of flowers, crowded, sessile or stalked, floral leaves lanceolate, subamplexicaul, broader at the base, pappus much shorter than the achenium. *C. Endivia*, or the common ENDIVE, cultivated throughout Europe, is supposed to have been introduced from India, where it is well known by its name of *Kasnee*. This species, like the former, has two or more heads, sessile or stalked, but with the floral leaves broad-ovate, cordate at the base and amplexicaul, pappus four times shorter than the achenium. The cultivation and uses of the ENDIVE have been treated of under that article, and of the present species under CHICORY, under which name it is more commonly known, and especially since it has been so extensively imported from the Continent as a substitute for coffee.

SUCCULA'TÆ, the name of a natural order of plants in the 'Fragments of a Natural System' of Linnæus, adopted by Bartling. It includes those families which are remarkable for the succulent character of their leaves, as Saxifragaceæ, Crassulaceæ, Ficoidaceæ, &c. All plants with thick leaves which abound with cellular tissue containing a watery secretion are called succulent. In these plants the cuticle of the leaves is remarkably destitute of stomates, and thus the transpiration of their juices is prevented. They are mostly inhabitants of arid climates, where they are supplied with only a small quantity of moisture and exposed to great heat.

SUCHONA, River. [DWINA; RUSSIA.]

SUCK, River. [SHANNON.]

SUCKERS. [STEM.]

SUCKLING, SIR JOHN, an English poet, was born at Whitton, in Middlesex, 1608-9. His father was one of

the principal secretaries of state and comptroller of the household to James I., and was by descent of a Norfolk family. The son is said to have shown in his boyhood great readiness in the acquisition of languages. We are not clearly informed as to the place and manner of his education. Aubrey thinks that he was at school at Westminster, but this fact does not seem certain. In 1623 he matriculated at Trinity College, Cambridge, and in 1628, about a year after his father's death, travelled abroad. In 1631 he joined the army of Gustavus Adolphus, king of Sweden, and probably remained on the Continent till 1632. On his return to England he led the life of a courtier, and was distinguished among his contemporaries not less by the brilliancy of his wit than by the splendid appearance which he maintained by the most lavish expenditure. Among his companions were Lord Falkland, Carew, Shirley, and Davenant; from the last of whom Aubrey derived most of his anecdotes of Suckling, whom he has thus described (*Lives of eminent Men, Bodleian Letters*, ii., part ii., 545):—'He was famous at court for his ready sparkling wit, which was envied, and Sir William (Davenant) says he was the bull that was bayted; he was incomparably ready at reparteeing, and his wit most sparkling when most set on and provoked.' While pursuing a course of fashionable pleasures, among which gambling seems to have most attracted him, he became engaged in a quarrel with a brother of Sir Kenelm Digby, and received from him a severe beating, which he does not appear in any way to have resented. After this dishonour, his associates looked coldly on him, and the consequent loss of reputation seems to have been accompanied by the decline of his fortunes. About this time we find the first notice of him as an author; in 1637 was published his 'Session of the Poets;' in 1638, his 'Aglaura;' and in 1639, his 'Brennoralt,' under the title of 'The Discontented Colonel,' a satire on the rebels. When the disturbances broke out in Scotland, Suckling equipped a troop of 100 horse in the king's service, and so magnificently, that they cost him, it is said, 12,000*l.* This extravagance was much ridiculed, and the misconduct and defeat of his men in 1639, in the battle between the Scotch and the Royal army, gave occasion for a ballad, more coarse than humorous, said to have been written by Sir John Mennis, a wit of those times, and which is printed in a poetical miscellany entitled 'Musarum Deliciæ, or the Muses' Recreation, containing several pieces of poetique wit,' 2nd edit., 1656. (Percy, *Antient Ballads*, ii., 322.) In 1640, on the meeting of the Long Parliament, Suckling was returned member for Bramber, and took an active share in the party strife that followed; a letter of his is extant, addressed to Henry Jermyn, afterwards earl of St. Albans, in which he discusses at some length the critical situation of the king. In 1641 he joined in a plot to rescue Strafford from the Tower, and was in consequence summoned before parliament, and accused of being an accomplice in a design to bring over the French; upon this he fled to France, and died soon afterwards in that country.

His death is said to have been caused by a fever, or, according to another story, inscribed on his portrait at Knowle in Kent, by a wound in the heel from a rusty nail placed purposely in his boot by his valet, who, after robbing him, wished to ensure safety in flight by disabling his master from pursuit. According to Aubrey, he poisoned himself at Paris. In a pamphlet entitled 'A Letter sent by Sir John Suckling from France, deploring his sad Estate and Flight,' London, 1641, he is said to have stayed some time at Rouen after his arrival in France, and to be then living with his wife at the Hague; but no reliance can be placed upon such a production. His death must have been before 1643, as in that year was printed, at London, 'A Copy of two Remonstrances brought over the river Stix in Caron's Ferryboate, by the Ghost of Sir John Suckling.' His works are:—1, 'Fragmenta Aurea,' London, printed by Humphrey Moseley, 1646, 8vo., with a portrait of the author, containing poems, letters, and an Account of Religion by Reason; in some of his poems he is said to have been assisted by Sir John Mennis. (Wood's *Athen. Oxon.* (Bliss), iii., 926.) 2, 'The Goblins,' London, 1646. 3, 'Fragmenta Aurea,' 1648, no portrait. 4, 'An Account of Religion by Reason,' London, 1658. 5, 'Aglaura, the Goblins, and Brennoralt,' London, 1658. 6, 'Letters to several Persons of Honour,' London, 1659. 7, 'The Sad One,' a tragedy, London, 1659. 8, 'His last Remains,' London, 1659. 9, His Works—Poems, Plays, Letters, Tonson, London, 1709, 8vo., with portrait; again, by Tonson, ibid., 1719, 8vo., with portrait; again, 12mo., 1770, no portrait; incorrectly, according to Chalmers, 'British Poets,' who has printed selections from his poems, omitting the more licentious.

A work entitled 'Selections from his Works,' with a Life prefixed by Rev. Alfred Suckling, London, 1836, has furnished nearly all the few facts contained in this scanty biography. The reader may also consult his Life, by Chalmers, the pamphlets about him already quoted; and a folio sheet printed in 1641, entitled 'The Sucklington Faction.'

In person Suckling was about the middle size, though but slightly made, with a graceful carriage. In the edition of his Works by his namesake is an engraving from a portrait by Vandyke, and two more by that master are there mentioned. His poems relate almost entirely to the passion of love; the fortunes of a lover and the feelings arising from his successes and reverses are described with the accuracy of one personally experienced in such adventures. These compositions, written in the transition period between an age of thought and learning, and an age of careless dissipation, present in singular combination the characteristics of the passing and the coming generation. In the more or less pedantic love of classical allusion, and in the strained intricacy of wit, the style of Suckling somewhat resembles that of his contemporaries; while in the licentiousness of his subjects, the gaiety and ease of expression, and the strange mixture of grossness and refinement of feeling, he still more reminds us of the court-poets of the reign of Charles II. His ballad of 'The Wedding' has been justly celebrated for the truth and naïveté of description, and the happy boldness in the use of homely imagery. The songs, 'When, dearest, I but think of thee,' and 'Tell me, ye juster Deities,' are among the best of his pieces. His letters are written in remarkably pure English, but in a style too studied and elaborate for such compositions.

SUCTORIAL CRUSTACEANS. M. Milne Edwards, in his valuable *Histoire Naturelle des Crustacés* (*Suites à Buffon*), remarks that this great division of the class *Crustacea* is connected intimately with the *Entomostraca*, and especially to the order *Copepods*, and he acknowledges that it would have been perhaps more natural not to separate it so definitely from them as he has done. For the rest, he adds, the group is distinguished from all the animals of the same class by the conformation of the buccal apparatus. In fact, he observes, the mouth, instead of being furnished with foliaceous jaws and mandibles proper for dividing solid aliments, is prolonged into the form of a beak, and cannot give passage to any but liquid substances. These crustaceans therefore are nourished by the juices which they obtain from the bodies of other animals only; and this organic disposition renders them essentially parasitic. But this peculiarity of structure, notwithstanding all its physiological importance, brings with it rather slight anatomical differences; for, in the crustaceans, as in the insects, the same parts are modified in their form, to constitute, according to the demand, an apparatus of mastication, or an organ of suction. This last is essentially composed of a conical tube resulting from the elongation of the labrum and the lower lip. There are almost always to be found two styliform pieces, which are evidently the analogues of the mandibles of the masticating crustaceans (Crustacés Broyeurs), but which here fulfil the office of small lancets, or rather, of the instrument employed in surgery in dropsical cases known as the trochar. Lastly, there exist ordinarily on each side of the base of this beak other appendages, the principal of which appear to represent the jaw-feet of the superior crustaceans, and serve the animal as the instruments to hook or attach itself to its prey. The feet are, in general, formed as in *Cyclops* [Branchiopoda, vol. v., p. 340] and the other *Copepods*, that is to say, they are short, and furnished with two natatory oars composed of many joints, and it is worthy of note, that, as in the greater part of the crustaceans, the number of these organs amounts to but four pairs; but, in the group before us, they become deformed by age, and sometimes completely disappear. Another trait of resemblance between the *Suctorial Crustaceans* and the *Copepods*, is furnished by the metamorphoses which they undergo in their youth; and it is a remarkable fact, that whilst in the adult state they offer the most variable forms, they have at their birth the ordinary conformation in all the young *Copepods*, and the greater part of the young *Branchiopods*; in the first period of their existence it is even impossible to distinguish them from the young of *Cyclops*.

M. Milne Edwards remarks that this subclass divides

itself naturally into two principal orders, and he has thought it right to add a third provisionally. This last, he observes, is ordinarily arranged by zoologists among the *Arachnids* [ARACHNIDA], but he is of opinion that their more proper place is in the class *Crustacea*. The three orders proposed by M. Milne Edwards are the *Siphonostomes*, the *Lerneans*, and the *Araneiform Crustaceans*.

1. SIPHONOSTOMES.

This order was established by Latreille, and comprehends all the *Suctorial Crustaceans* whose thorax, composed of many distinct joints, is furnished with natatory feet.

M. Milne Edwards describes these animals as having the body divided into three parts: the head, the thorax, and the abdomen. The first is large, and carries a pair of antennæ, a sucker furnished with styliform mandibles, and anchor-like or prehensile jaw-feet, generally three pairs in number. This cephalic portion of the body is, in general, more or less clypeiform, and is confounded with one or two of the first thoracic rings. The normal number of the constituent segments of the thorax is five, but in consequence of the soldering of the parts, this middle portion of the body offers mostly only two, three, or four distinct joints. The last thoracic ring is apod, and, in the female, carries two or three oviferous tubes. Finally, the abdomen is, in general, rudimentary, and is only furnished with a single pair of appendages, disposed so as to constitute ordinarily a small caudal fin. The general form of the body varies much, and sometimes departs considerably from that which may be considered as normal in this class of annulose animals.

The *Siphonostomes* undergo considerable metamorphoses in their youth, and do not become parasites till they have changed their skin once or many times: they swim at first with ease, but after having fixed themselves, they become more or less deformed, and do not quit their place except slowly and with difficulty.

M. Milne Edwards divides the *Siphonostomes* into two families—the *Peltocephala* and the *Pachycephala*.

Peltocephala.

This family has less affinity with *Cyclops* than some of the *Pachycephala*, but they offer a more complicated structure, and consequently appear to M. Milne Edwards to deserve precedence.

The *head* is very large, shield-like, and, in general, much larger than the thorax or abdomen; it resembles a disk slightly convex above, delicate on its edges, and truncated behind, where it is confounded with the first rings of the thorax. On its upper surface two small smooth eyes may be almost always distinguished; they are closely approximated to the median line. Forward it is continued with two frontal blades more or less distinct, and directed transversely. The *thorax* is composed of a variable number of joints; sometimes two only are distinguishable, sometimes three or even four may be counted, according as the three first segments are confounded with the head, or this soldering extends to but two of these rings, or even to one only. For the rest, the aspect of this portion of the body varies much, for sometimes the dorsal segment of these rings presents nothing remarkable, and sometimes it gives rise to great laminæ, which resemble the elytra of insects.

The *abdomen* is but little developed, and presents no appendage below, but terminates by two small natatory blades ciliated on the edges, or by a species of trifoliated fin.

The *appendicular system* presents, in all the animals of this division, the same essential characters, and is composed of a pair of antennæ, a buccal apparatus, and four pairs of feet.

The *antennæ*, two in number only, are inserted very far from each other, and are short, flattened, and directed outwards; they are always composed of two or three small lamellar joints, and are never setaceous nor annulated.

The *buccal apparatus* is composed of a sucker, of divers rudimentary appendages, situated on each side of its base, and of three pairs of anchor-like jaw-feet. The *sucker* is large, conical, and directed backwards; two unequal pieces are there to be distinguished, which are soldered by the edges throughout the greatest part of their length, but remain free towards the end, and leave between them, at the summit of this species of beak, a circular or triangular aperture: one of these laminæ is inserted between the mouth and the front, and represents the *labrum* or upper lip; the other, situated backwards, is analogous to the lower lip of the masticating crustaceans. Between the base of these two lips springs, on each side, an appendage, which evidently replaces the *mandibles* of these last animals; but which, instead of being short, stout, and dentiform, is slender, very much elongated, and similar to a stylet with a dentilated point; these styliform jaws penetrate into the beak by means of a slit situated near its base, and advance into its interior, so as to come out by the terminating aperture, and serve as a pair of lancets when the animal wishes to suck its prey. A little outwards is found a second pair of appendages, which is reduced to a nearly rudimentary state, and seems to be the representative of the first pair of jaws of the ordinary *crustacea*; in general there is to be distinguished near the same point a styliform or forked horny piece, which seems to be the vestige of a third pair of buccal appendages, appendages which, in the masticating crustaceans, constitute the second pair of jaws. The *jaw-feet*, three pairs in number, offer considerable dimensions, and are ranged on each side of the siphon: the first pair seem to be reflected (refoulées) forward, for they spring in front of the edge of the upper lip, between the sucker and the antennæ, and by some naturalists they are considered as antennæ; they are stout, short, more or less misshapen, and each terminated by a hooked claw, by the aid of which the animal attaches itself to its prey. The second pair of jaw-feet are slender, and always composed of two principal joints of nearly equal length, the second of which carries, near its middle, a small appendage, and terminates by one or two hooks but little bent. The third pair of jaw-feet, situated more backward, are stout, in general short, and more or less completely subcheliform; the crooked claw which terminates them can be bent back on the penultimate joint, in manner of a claw.

The *feet* are four pairs in number, and are always more or less completely natatory; two pairs, and sometimes all, terminate by two oars, each composed of three joints, offering, generally, a very remarkable disposition of a nature to favour their action as natatory instruments, and which consist in a very considerable development of their basilary joint, and the soldering of that joint with an unequal sternal piece, so as to form, with the whole, a single transversal blade, as for the two feet; it is even to be remarked, that in general this basilary piece, which occupies the whole width of the corresponding ring, is much more developed than the terminal oars of those limbs, and constitutes, by itself, nearly the whole of the fin formed by the pair of feet thus modified. These four pairs of limbs belong to the four first thoracic rings, and spring, some from the cephalic buckler, others from the postcephalic portion of the thorax, varying in number according to that of the thoracic rings, which are confounded with the head. The last ring of the thorax carries none; but, in general, a pair of tubercles or lobules may be distinguished there, which appear to be the vestiges of a fifth pair of limbs reduced to a rudimentary state.

These crustaceans live as parasites upon fishes, but they are not permanently fixed to them, and when they let go their hold, they can change their place either by crawling slowly or swimming. The male is, in general, distinguished from the female by some peculiarities of structure, and by a very inferior size. The female nearly always carries her eggs in cylindrical tubes, which spring near the posterior border of the last thoracic segment on each side of the abdomen, and which often attain a very considerable length. The young, at their birth, resemble the young of *Cyclops*, and must undergo many moults before they finish their metamorphosis; little however is known at present of these changes. It is also to be noted that one often finds in the neighbourhood of the vulvæ small ampullæ, which are fixed there by a very narrow neck, and which may be spermatic reservoirs, analogous to those which M. Siebold made known in *Cyclops*.

M. Milne Edwards divides this natural family into three divisions or tribes—the *Argulians*, the *Caligians*, and the *Pandarians*.

Argulians.

This tribe consists of a single genus, *Argulus*, which infests fresh-water fish and the tadpoles of Batrachians, to which they adhere, but they are also found free, swimming about with vivacity.

Argulus foliaceus is known to most anglers: it is figured in Desmarest (*Crust.*, pl. 50, fig. 1), and there is a pretty wood-cut of it in Yarrell's *British Fishes*, vol. ii., p. 399.

Caligians.

There is nothing abnormal in the conformation of the thorax of this tribe, the thoracic rings being simple, and without dorsal appendages. The cephalic buckler is large, more or less oval, delicate on its edges, and furnished anteriorly with very well developed frontal laminæ, the lateral extremity of which covers the base of the antennæ: the posterior angles of this carapace are prolonged more or less far on each side of the thorax, and the portion of its posterior border, comprised between these two prolongations, is confounded with the first, or even the second or third first thoracic segments. The result is, that the thorax is only composed of two, three, or four distinct joints. The feet are furnished with long plumose bristles; and the abdomen is terminated by two small plates directed backwards, and carrying no lateral appendages.

Genera.

Caligus (see the article and the arrangement of M. Milne Edwards, who divides the genus into several sections, and records no less than fifteen species), *Chalimus*, *Trebius*, and *Nogagus*.

Pandarians.

The small crustaceans collected by M. Milne Edwards under this name, are remarkable for the lamellar prolongations with which the upper part of their thorax is furnished. These appendages, he observes, often resemble the elytra of insects, and their number is sometimes considerable; there may be as many as three pairs counted. In general the head is less enlarged and less clypeiform than in the *Caligians*, and the feet are only rarely furnished with plumose setæ; their terminal oars are often only represented by foliaceous submembranous lobes; and the abdomen frequently presents on each side of its terminal piece a more or less projecting lamellar appendage.

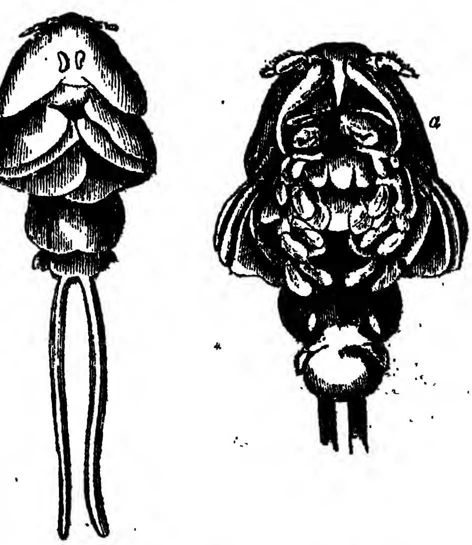
M. Milne Edwards subdivides this tribe into two small groups, principally characterised by the general form of the body, and by the disposition of the oviferous tubes, which in the one are exposed and extended in a straight line behind the body, whilst in the other these tubes are coiled upon themselves and hidden between the superior surface of the abdomen and a clypeiform lamina which springs from the last thoracic ring.

The genera *Euryphorus*, *Dinemoura*, *Pandarus*, and *Phyllophora*, form the first of these groups. *Cecrops* and *Læmargus* belong to the second.

Our limits will only permit us to illustrate this tribe by the genus *Phyllophora*.

The type of this last-named genus is, according to M. Milne Edwards, who established it, very remarkable from the lamellar appendages with which its back is covered. In its aspect it approaches the *Anthosomes*, but in the structure of its feet and in its general organization it is not separable from the *Pandarians*. The only species known is *Phyllophora cornuta*. Length about ten lines.

Locality.—Near Tongataboo.



Phyllophora Cornuta. (M. E.) *a*, seen from below

Pachycephala.

In this division of the order *Siphonostomes*, M. Milne Edwards describes the head as not enlarged, but lamellar and clypeiform as in the preceding family, and the antennæ, instead of being short, flattened, and biarticulate, as slender, cylindrical, elongated, and composed of five or six joints, the size of which diminishes gradually from the base towards the point of the organ. It is also to be noted that the apparatus of suction is, in general, less developed in these crustaceans, than in the *Peltocephala*, and the mode of conformation of these appendages which would appear to represent the jaw-feet is less constant: the feet are not soldered on the median line, and consequently do not constitute unequal fins, as is often the case in the preceding family.

M. Milne Edwards divides the *Pachycephala* into two natural groups. The *Ergasilians* and the *Dichelestians*: the first, he observes, establishes the passage between *Cyclops* and the *Lernæidæ*; the second, between these last and the *Pandarians*.

Ergasilians.

This small group closely approximates to *Cyclops*, and is remarkable for the pyriform conformation of the body, the size of the head, and the development of the abdomen.

Genera.

Ergasilius, *Bomolocus*, and *Nicothoa*. Species of *Ergasilius* are found attached to the gills of the pike and carp (*Erg. Sieboldii*); to those of the eel (*Erg. gibbus*); and to those of a *Silurus* (*Erg. trisetaceus*). The only species of *Bomolocus* known (*Bom. Belones*) is found attached to the branchiæ of the gar-fish (*Esox Belone*). *Nicothoa* includes but one species (*Nic. Astaci*) which is of a rosy colour, about a line in length, and is found upon the branchiæ of the lobster. The young *Nicothoæ*, on leaving the egg, resemble the young of *Cyclops*, and want the thoracic lobes which, when they are adult, give so strange an aspect to these animals.

Dichelestians.

This tribe is easily distinguished from the *Ergasilians* by the elongated form of the body, the smallness of the head, and the frequently rudimentary state of the abdomen. It is also worthy of note that their feet are much less developed than in the *Ergasilians*, and that the organs by the aid of which they fix themselves on their prey, are, on the contrary, more developed, announcing a more essentially parasitic life.

Genera.

Anthosoma, *Dichelestium*, *Nemesis*, *Lamproglena*.

But one species of *Anthosoma* is known (*Anth. Smithii*), about ten lines long, and found upon a *Squalus*. M. Milne Edwards remarks that the *Caligus crassus* of Abildgaard much resembles this species, but seems to be more stout about the head, and to have the cephalic buckler wider forwards.

Dichelestium, too, comprises but one species (*Dich. Sturionis*). It is about one inch in length, and fixes itself on the branchial apparatus of the Sturgeons. The thorax is divided into four portions in the male, and into five in the female, by interannular divisions. The abdomen is very small in the female, about half as large as the last thoracic ring in the male. Neither does *Lamproglena* include more than one species (*Lamp. pulchella*), which is found on the gills of the chub.

Lerneans. (Lernæidæ, M. E.)

This order is principally distinguished from the *Siphonostomes* by the rudimentary state of the whole appendicular system, which is only represented by vestiges of limbs or simple tegumentary lobes without articulations, and proper only to serve for anchoring the animal on the prey at whose expense it lives. The *Lerneans* are remarkable for the oddity of their shape, which, in general, departs greatly from all the ordinary forms in this class, and seems to be the result of a monstrous development. In youth their conformation is normal and much resembles the young of *Cyclops*; they are then provided with a frontal eye, and natatory oars which permit them to move with agility; but, after having undergone a certain number of moults, they cease to lead an erratic life. The females fix themselves on some other animal, and the males, which are much smaller, hook themselves, in general, under the abdomen of their female and near the vulvar aperture. The organs of locomotion, then rendered useless, waste away or become deformed, so as to be unfit for the office which they were originally intended to execute. The eye nearly always dis-

appears, and the general configuration of the animal changes, so as to make it not recognisable. The females especially acquire the most singular forms. They become very large, and solder themselves, so to speak, on their prey by the aid of simple cutaneous appendages or certain members transformed into immovable arms. The males remain extremely small, and depart less from their primitive conformation, but the head becomes larger, and the jaw-feet, transformed into instruments of prehension, and destined to fix the animal on the part which is to be its habitat, acquire a great relative development.

We must here pause for a moment, to mark this provision for the welfare of the animal. If all the young went to one fish, that of the parent for example, as would probably be the case if they were born blind and with organs only fit for attachment, the fish would die, and the whole generation of parasites would be defunct with it. But the young *Lernæa* is hatched in a form that enables it to swim about and feed on minute animals; and, being furnished in this state with eyes, it has not only the means of temporary subsistence whilst leading a wandering life, but also of selecting its proper species on which it is destined to feed. Then the locomotive limbs are gradually changed to organs of attachment, the eyes disappear, nutrition is the object till the organs of generation are fully developed, and, in this, as in some other cases, the perfection of the animal consists not in the enjoyment of locomotion and vision, but in that state which renders it fit for the continuation of the species.

M. Milne Edwards remarks, that zoologists have mistaken the true nature of the Lerneans, and have separated them from the *Crustaceans*, to place them among the worms. Desmarest, he observes, is one of the first authors who have clearly indicated their natural relationship with the ordinary crustaceans; but, he adds, it is only since the knowledge of the transitory forms put on by these parasites in the commencement of their life, that one has been able definitively to assign to them a place in the natural series of the crustaceans, and the acquaintance with these changes is principally due to that skilful observer, M. Nordmann. M. Milne Edwards observes, that there is no branch of the natural history of the crustaceans so little advanced as that relative to the *Lerneans;* nearly all remains to be done, and he expresses a hope that M. Nordmann will not abandon a pursuit which has already conducted him to results so important to science.

M. Milne Edwards divides the *Lerneans* into three families, characterised by the manner in which these parasites attach themselves to their prey. Some fix themselves by means of great brachiform appendages, united together towards the end, and terminated by a horny median *bouton.* Others adhere by their jaw-feet, which are armed with very strong hooks. Others again attach themselves by the whole head, which is furnished for this purpose with horny prolongations of various forms. The first correspond to the *Lerneopods* of M. de Blainville, and may be designated as *Lerneopodians;* the second have the genus *Chondracanthus* for their type, and form M. Milne Edwards's family *Chondracanthians;* and the third he denomintes *Lerneocerians,* because the genus *Lerneocera* belongs to that family, and the name recalls one of their principal characters. With regard to the establishment of generic divisions, and the characters of species, he can only, he observes, refer, in the greater number of instances, to the mode of organization in the females; for the males are nearly entirely unknown to him, and, in his descriptions, the females are designated, unless the contrary is specified.

Cnondracanthians.

The female *Chondracanthians* fix themselves upon their prey by the aid of small anchor-like jaw-feet, inserted at the anterior extremity of the head, and under the front. The thoracic appendages do not serve for the same use, and have the form of ordinarily two-oared feet of extreme smallness, or fleshy lobes, free at their extremity, and not prehensile. The head is, in general, tolerably distinct from the thorax, and nearly always carries a pair of antennæ, and two pairs of unciform and anchor-like jaw-feet. On the sides of the mouth may be ordinarily perceived a pair of appendages, which represent the second pair of jaw-feet, and which are sometimes anchor-like, similar to the others, but are often rudimentary. The mouth is sometimes situated very far behind the anterior jaw-feet, and is armed with small appendages representing the mandibles. The number and disposition of the appendages corresponding to the thoracic feet vary; sometimes two pairs only are to be counted, sometimes three, and even four. The oviferous tubes spring from the posterior edge of the body, so that the abdomen is rudimentary, and is only represented by one or two small median tubercles. The male is often found attached under the anus of the female: he is extremely small, and does not resemble her in the least, but differs little from the males of the succeeding family. (M. E.)

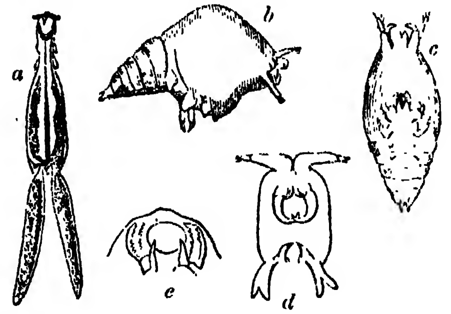
Genera.

Selius, Æthon, Clavella, Cycnus, Tucca, Peniculus. Lernanthropus, Chondracanthus.

Selius consists but of one species (*Sel. bilobus*), found on the branchiæ of the Dotted Polynöe; nor does *Æthon* comprise more, consisting only of *Æthon quadratus*, found on a *Serranus*, and about a line in length. *Clavella* has two species; *Cl. Hippoglossi*, found on the Holibut, and *Cl. Scari*. *Cycnus* has only one species (*Cyc. gracilis*), found on the branchiæ of a cod-fish; and this is the case with *Tucca*, which has only one (*Tuc. impressus*), found on *Diodon Hystrix*. *Peniculus* has but one (*Pen. Fistula*), found on *Zeus Aper*. *Lernanthropus* consists of two species, separated by M. Milne Edwards into two sections; *Lernanthropus Pupa*, found on a Brazilian *Platax*, and *Lern. paradoxus*, found on the mullets. M. Milne Edwards remarks that *Lernanthropus Musca* (De Bl.), found on a *Diodon* from Manilla, belongs to his first section.

Chondracanthus is separated by M. Milne Edwards into two sections, with subdivisions, and contains seven species:

Ch. cornutus, found on several flat-fish (*Pleuronectes*); *Ch. crassicornis*, found on a wrasse; *Ch. Soleæ*, found on soles; *Ch. Triglæ*, found on gurnards; *Ch. Merlucci* (from which the *Ch. Xiphiæ* of Cuvier does not appear to M. Milne Edwards to differ, and to which he thinks *Lernæa radiata* of Müller, found in the buccal cavity of *Coryphæna rupestris*, appears to be very close); *Ch. Zei;* and *Ch. Delarochiana*, the last found upon the thunny.



Chondracanthus cornutus.

a, female magnified after Nordmann; *b*, male seen in profile and more highly magnified; *c*, the same seen from below; *d*, head of the female seen from below; *e*, mouth still more highly magnified.

Lerneopodians.

In the females of this group the head is formed nearly as in the *Chondracanthians*, that is to say, distinct from the thorax, furnished with a pair of antennæ, and armed with two pairs of anchor-like jaw-feet. But the anterior jaw-feet are less proper for serving these small crustaceans for attaching themselves to their prey, and the thorax, which carries neither feet nor fleshy appendages, similar to those which represent the two first pairs of thoracic members in the preceding division, give origin to a pair of very large brachiform prolongations, which unite together sometimes at their base, sometimes towards their extremity only, and terminate by a horny *bouton*, by the aid of which the parasite strongly adheres to the animal on which it has established its dwelling. These organs of adhesion appear to replace the first pair of thoracic limbs.

The male of only a small number of *Lerneopodians* is known, and where known differs extremely from the female. He has the body divided into two very distinct parts; one anterior, the cephalic, which carries the antennæ, a pair of anterior unciform jaw-feet, the sucker, and, farther back, two pairs of well-developed appendages, which represent the posterior jaw-feet and the arms of the female, but which have the form of stout hands carried on a cylindrical peduncle, and terminated by a small ill-formed pincer. The young undergo the ordinary metamorphoses. (M. E.)

There are six genera:—*Tracheliastes*, *Basanistes*, *Achtheres*, *Brachiella*, *Lerneopoda*, and *Anchorella*.

Thacheliastes has three species, divided into two sections: *Tr. polycolpus*, found on the fins of the chub; *Tr. maculatus*, found on the scales of the bream; and *Tr. Stellifer*, found on the branchial arches or within the mouth of *Silurus Glanis*.

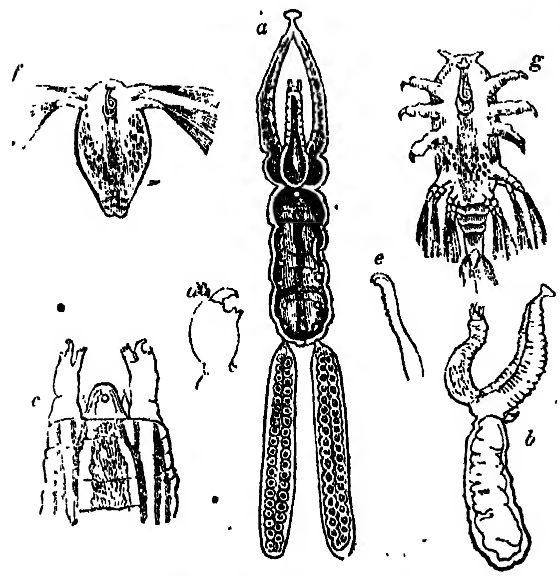
Basanistes comprises two species:—*Bas. Huchonis*, found on the gill-cover of the huchen (*Salmo Hucho*), and *Bas. salmonea*, found on the grayling. M. Milne Edwards states that *Lerneopoda Brongniartii* (De Bl.) belongs to this genus.

Achtheres consists of but one species (*Ach. Percarum*), found on the fins of the river Perch and of the Sandra. Length about two lines.

Brachiella comprises five species, distributed into two sections, with subdivisions:—*Brachiella Thynni* (length about ten lines, of male about half a line), found on the gills of the Thunny; *Br. impudica* (length about four lines, of male about a third of a line), found on the gills of the Haddock (*Gadus Æglefinus*); *Br. bispinosa* (about three lines in length, male unknown), found on the gills of the Sapphirine Gurnard (*Trigla Hirundo*); *Br. rostrata*, closely approaching the preceding, found in the Greenland Seas upon *Pleuronectes pinguis*; and *Br. Lophii*, found on the gills of the Sea-Devil, Toad-fish, or Frog-fish, at Naples.

Lerneopoda consists also of five species, divided into two sections:—*Lerneopoda stellata*, found on the fins of a Sterlet in Norway; *Lern. elongata* (about two inches in length), found fixed to the eye of a Shark in the Polar Seas; *Lern. Carpionis*, nearly approaching the preceding, found on the Salmon in the north of Europe; *Lern. Galei* (length about three lines, male about the same size), found on the fins of a Tope Shark (*Milandre*); and *Lern. obesa* (about two lines in length), found upon *Squalus Acanthias*, the Picked-dog, or Hound-fish.

M. Milne Edwards thinks that *Lern. Dalmanni*, found on *Raia Batis*, the Skate; *Lern. bicaudata* (about two lines long), found on the Red Gurnard; and *Lern. salmonea*, belong to this genus. The last species does not seem to M. Milne Edwards to be determinable specifically, and he makes the same remark on the *Lernæa* found by Hermann on the Dace.



Tracheliastes polycolpus. (M. E.)

a, female magnified and seen from above; *b*, the same seen on the side and deprived of the oviferous bags; *c*, anterior extremity of the body more highly magnified; *d*, appendage representing the second pair of jaw-feet; *e*, mandible; *f*, larva of the same; *g*, second age of the larva.

Of *Anchorella* five species are recorded, distributed into two sections:—*Anch. emarginata* (about six lines long), found upon the gills of the Wolf-fish (*Anarrhicas Lupus*); *Anch. brevicollis* (about four lines long), found fixed on the anal fin of the Variable Cod-fish (*Gadus callarias*); *Anch. ovalis* (about two lines long), found upon the Red Gurnard; *Anch. rugosa* (about three lines long), found on the Wolf-fish; and *Anch. uncinata*, found on the gills of divers *Gadi*.

M. Milne Edwards is of opinion that *Lerneomyzon pyriformis* and *Lerneomyzon pinnarum* (De Bl.) belong to this genus, as well as *Lernæa adunca* of Strom and *Lernæa anomala* of Abdilgaard.

Lerneocerians.

The female *Lerneocerians*, like the *Chondracanthians*, fix themselves to their prey by the anterior extremity of their body only, and have no brachiform thoracic appendages serving for this purpose, as may be seen in the *Lerneopodians*; but the arming of their mouth is far from having the form which this apparatus offers among the *Chondracanthians*, and the whole head of the parasite is plunged in the tissue of the animal on which it establishes its dwelling, and is there retained by horny prolongations, of varied form, which spring from its posterior or occipital part. In general the head is not very distinct from the thorax, and seems to be completely deprived of antennæ; the mouth is armed with but one pair of jaw-feet, which are simple and unciform. The feet, when they exist, are of extreme smallness, and sometimes no trace of them is to be perceived. The portion of the trunk which is situated behind the point where the oviferous tubes take their origin, and which represents the abdomen, is, in general, much more developed than in the other females of the same order.

The *male* of the *Lerneocerians* is unknown, except in very few species; and, where known, seems as imperfect as that of the *Chondracanthians*; his body is globular, offers no distinct thorax, and does not carry rudiments of feet behind the appendages which represent the jaw-feet. The metamorphoses which the young undergo are analogous to those of the other *Lerneocerians*. (M. E.)

Genera.

Penella, *Lerneonema*, *Lerneocera*, *Lernæa*.

Penella consists of four species, divided into two sections:—*Pen. Sagitta* (about four inches long), found on *Lophius marmoratus*; *Pen filosa*, and *Pen. Blainvillii*, the last found on the Flying-fish, *Exocætus volitans*; and *Penella Sultana* (about an inch long), found in the mouth of *Carenx Ascensionis*.

Lerneonema, also divided into two sections, comprises three species:—*Lern. Lesuerii* (about two inches long), found in the American Seas upon the Flying-fish; *Lern. monilaris* (about an inch long), found fixed to the sclerotic coats of the eye of the Sprat (*Clupea Sprattus*); and *Lern. abdominalis* (about twenty lines long).

M. Milne Edwards states that *Lerneocera surriraiis* (De Bl.) belongs to this group, and that it much resembles the preceding species, but is distinguished by the brevity of the abdominal portion of the body; and he is of opinion that the genus *Sphyrion* of Cuvier is too imperfectly known to enable him to determine its natural affinities, though it appears probable to M. Milne Edwards that its place is between *Penella* and *Lernæa*.

Lerneocera comprises four species, divided into two sections and subdivisions:—*Lern. cyprinacea* (about eight lines long), found in Sweden on *Cyprinus Carassus*; *Lern. esocina*, *Lern. cruciata*, found in Lake Erie, on *Cichla ænea* (Lesueur); and *Lern. radiata*, found on *Clupea Tyrannus*, United States of America.

M. Milne Edwards thinks that *Lernæa ocularis* of Cuvier belongs to the second section of the genus *Lerneocera*. It is found fixed to the eye of Herrings.

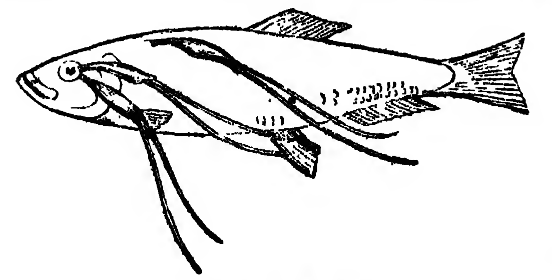
Lernæa consists of two species, each placed in a separate section:—*Lernæa branchialis*, found on the gills of several species of *Gadi*, in the North Sea; and *Lernæa multicornis*.

M. Milne Edwards states that *Lernæa cyclopterina* is distinguished from *Lernæa branchialis* by certain tubercles about the head and neck. He remarks that M. Kroyer has represented it without horns, but he thinks that arose from the mutilation of the animal observed by M. Kroyer. This parasite is found in the Greenland Seas on *Cyclopterus spinosus*.

Lerneonema monilaris, magnified. (M. E.)

The subjoined cut, from Sowerby's 'Miscellany,' shows the external appearance of a sprat infested by these Lerneans. Mr. Sowerby names the parasite *Lernea Sprattæ* (*Lernæa Spratti*). These crustaceans are stated to be lumi-

nous at night; and the fishermen say that the shoal is often headed by fish so infested, which they call Lanthorn Sprats.



Lerneans in situ on a Sprat.

ARANEIFORM CRUSTACEANS, OR PYCHNOGONIDS.

M. Milne Edwards states that it is not without doubt that he has arranged in this place a small group of articulated animals which have been considered by the greater part of zoologists as belonging to the class of *Arachnids*, but which seem to him to have more analogy with the *Crustaceans*, for they have no tracheæ nor pulmonary sacs for aerial respiration, and appear to respire oxygen beneath the water only by means of the general surface of the common teguments, as he had already pointed out in many inferior crustaceans.

In the general form of the body these animals approach the LÆMODIPODA, and especially *Cyamus*. Their *head* is elongated, sometimes cylindrical, sometimes conical, and presents at its extremity a trilobated buccal orifice. The *thorax* is constantly divided into four segments, and the *abdomen* is only represented by a small tubular joint fixed to the posterior edge of the last thoracic ring. The head carries no appendages, and the eyes, four in number, are grouped on a small median tubercle, situated on the dorsal surface of the first joint of the thorax. This segment often carries at its extremity a pair of jaw-feet terminated by a well-formed pincer, and sometimes furnished with a palp, which is elongated and composed of many joints. In the male, the number of pairs of feet is equal to that of the joints of the thorax; but in the female there is a pair of pediform supplementary appendages fixed to the first joint of the thorax, bent back under the feet properly so called, much smaller than them, and serving to carry the eggs. The feet are very long, directed outwards, and composed of nine joints, the last of which constitutes a more or less sharp claw.

The digestive tube traverses the body in a straight line, and presents in one of the genera of this family (*Nymphum*) a very remarkable disposition; it gives origin, to the right and left, to a series of prolongations, which are tubular and closed above, which advance very far in the interior of the corresponding feet, and which are the seat of a peristaltic motion. There exists besides a vague circulation. No trace of respiratory organs is perceptible, and the disposition of the organs of generation is not known; it is only to be remarked that in the *Pychnogonons* may be perceived on the second joint of the posterior feet a pore which seems to be the orifice of this last apparatus.

The *Pychnogonids* are all of small proportions, and live in the sea; some are found under stones, others live, it is said, hooked on to fish or other marine animals; but, otherwise, nothing is known relative to their habits.

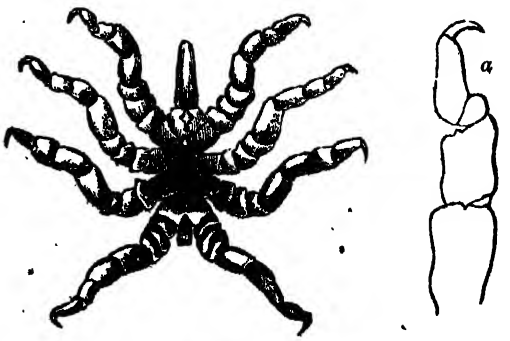
These animals form a small family, which Dr. Johnston, to whom zoologists are indebted for a good work on this subject, divides into five well-characterised genera. (M.E.)

Genera.

Nymphum, *Pallene*, *Phoxichilidium* (*Orythia*,* Johnston), and *Pychnogonum*.

Our limits will only allow us to illustrate this group, which still requires the close attention of the physiologist and comparative anatomist, by one genus. *Pychnogonum* is distinguished from its congeners by the stoutness of its form, and the size and shortness of its feet, which are strongly contrasted with those of *Nymphum gracile*. Only one species appears to be known, *Pychnogonum littorale*; the accessory feet of the female are very short. Length about four lines. This Araneiform crustacean inhabits our seas and those of France, and is found on Ascidians and various fishes.

* Previously used for another crustacean. [OXYSTOMES.]



Pychnogonum littorale, magnified.
a, foot of the same, more highly magnified.

The reader should refer to the writings of Fabricius, Latreille, Brunnich, Montagu, Lamarck, Leach; and especially of Dr. Johnston, in *Zool. Journ.*, *Miscell. Zool.*, and *Mag of Zool. and Botany*, relative to this highly interesting order of animals.

SUDBURY. [SUFFOLK.]

SUDERMANIA. [SWEDEN.]

SUDETES, or SUDETCH MOUNTAINS. [GERMANY.]

SUDRAS. [HINDUSTAN, p. 231.]

SUET is a variety of the fatty or adipose tissue of animals, accumulated in considerable quantity about the kidneys and the omentum, or caul, of several of the domestic quadrupeds. There are several kinds of it, according to the species of animal from which it is procured, such as that of the hart, the goat, the ox, and the sheep (ovis aries). This last, which is whiter than beef-suet, is officinal. It belongs to the class of saponifiable fats. In the recent state it is white, easily broken, being solid at the ordinary temperature of the air, subdiaphanous, scarcely possessed of odour, or only of a slight peculiar one, due to the hircine, which in the process of saponification evolves a volatile strong-smelling acid (hircinic acid of Chevreul), but possessing a very disagreeable one when putrifying. It readily spoils on exposure to the air, becoming rancid and yellow, but may be restored again to whiteness by chloride of lime or chloride of magnesia. For this purpose, for each hundred parts of suet from two to four parts of chloride of lime are to be dissolved in from four to eight times its weight of water, and to be mixed warm, and as much dilute sulphuric acid is to be added as is necessary to decompose the chloride.

Suet consists of about three-fourths of stearine, with some elaine, and a little hircine, and margarin; the preponderance of stearine renders it the most solid of animal fats. It liquefies with a gentle heat, and the prepared suet of the Pharmacopœia is obtained by melting it over a slow fire, and straining it, to separate the membranous portion. It is used as an ingredient in cerates, plasters, and ointments.

After being melted, it is little prone to spoiling, and by pouring it over various articles, such as potted char, from which it thoroughly excludes the air, it assists greatly in preserving them.

It has been employed also by M. Ludensdorff for preserving the *fleshy fungi*, or mushrooms, by boiling them in it (which thus filled their pores and cells, and penetrated the very substance), and then covering them with a coat of varnish. It does not however always succeed in preserving the colour and form. (See Klotsch, in Hooker's *Botanical Miscellany*, ii., p. 159.)

SUETO'NIUS (CAIUS SUETONIUS TRANQUILLUS). The few particulars which are known of the life of Suetonius are derived chiefly from his own writings and from the epistles of his friend the younger Pliny.

The time of his birth is not known, but as he states that he was a young man (adolescens) twenty years after the death of Nero, the time may be fixed approximately. He also says that his father was Suetonius Lenis, a tribune of the thirteenth legion, and of equestrian family (*Oth.*, 10); and that he was in the battle of Bebriacum, in which Otho was defeated by Vitellius. It has been remarked that the name Lenis signifies the same as Tranquillus; but it is said, that instead of 'Lenis,' some manuscripts have 'Lætus.' There are extant several letters from Pliny the

Younger to Suetonius, the son, from one of which (i. 18) it appears that Suetonius was then practising at the bar. In another letter (v. 11) Pliny urges him to publish some works which he had written. At the request of Pliny, Trajan granted Suetonius the Jus trium liberorum, by which he obtained all the privileges of those who actually had children, and was freed from the disabilities imposed by the Lex Julia et Papia Poppaea on those who were married and had no children. He was Magister Epistolarum to Hadrian, but lost his office at the same time that Septitius Clarus, who was Praefectus Praetorii, and many others were dismissed by Hadrian on the ground, which is very obscurely stated, that they had, without the emperor's permission, conducted themselves towards his wife Sabina with more familiarity than was consistent with the respect due to the Imperial family. (Ael. Spart., *Hadrian*, ii.)

Nothing more is known of Suetonius. His friend Pliny calls him a most upright and learned man, whose character rose in his estimation the better he became acquainted with him. Suetonius was a voluminous writer; a list of his works is given by Suidas (v. Τράγκυλλος) as follows: one book on sports or pastimes among the Greeks; two books on Roman games and shows; one book on the Roman year; one book on the notes or marks used in writing; one book on the 'Respublica' of Cicero; a treatise on proper names, and the forms of garments, shoes, and other articles of dress; a treatise on words of bad omen; two books on Rome and its institutions and manners; a work in eight books on the Cæsars from Julius Cæsar to Domitian, which is still extant; and a Stemma or Genealogy of illustrious Romans. He also wrote a work on kings, in three books; a work entitled 'De Institutione Officiorum;' a work on the Praetors, the eighth book of which is quoted by Priscian; and a work 'De Variis Rebus.'

The only complete work of Suetonius, which is extant, is the 'Lives of the Twelve Cæsars,' now printed in twelve books or parts, but sometimes distributed into eight books, as appears from Suidas and from several manuscripts. This work comprehends, as already observed, the Cæsars from C. Julius Cæsar, the Dictator, to Domitian, both included. It has been conjectured that the first part of the Life of C. J. Cæsar is wanting, because it begins rather abruptly with the events of his sixteenth year: but the conjecture has nothing else to support it. The biographies of Suetonius are peculiar in their construction. He does not strictly follow the chronological order of events. There is no attempt at rhetorical ornament or effect: the style is characterised by correctness, brevity, precision, perspicuity, and simplicity; there are no idle words. There is an air of impartiality about the whole work, from which a reader derives greater confidence in the truth of the narrative, than from the laboured pictures of Tacitus. Vopiscus calls him a faultless and most impartial writer, and a lover of brevity. The vices of the Cæsars are stated circumstantially and drily, as facts well ascertained. These biographies abound in facts. Indeed their chief merit consists in being a most copious source of materials. Accordingly the style has been appropriately called by La Harpe anecdotical. That Suetonius was a learned Roman, as his friend Pliny states, is apparent from his work. He seems to have had a competent knowledge of the antiquities and the institutions of his country. Like Tacitus, he frequently mentions the legislative enactments (*Senatus Consulta*) which were passed under the Cæsars, but neither is he nor any other Roman historian always a safe guide in such matters. The work of Suetonius does not affect to be historical, yet it comprehends a brief notice of all the public events which happened in the life of each Cæsar. It is a valuable work for the early Imperial times, and if used judiciously with the other authorities, it might form the basis of something like a satisfactory history of this period. He consulted official documents, and availed himself of sources of information which are now entirely lost.

The editions of the 'Lives of the Cæsars' are very numerous. About fifteen editions were printed before 1500. The oldest edition that bears a date is that of Rome, 1470, fol., by G. A. Campani. One of the best editions is that of Isaac Casaubon, fol., Paris, 1610. There is a small useful edition, with a selection of notes, by J. Schild, 8vo., Lugd. Bat., 1647, &c. Among the other editions of Suetonius are those of J. G. Graevius, Oudendorp, and Ernesti. A list of the editions is given in Schweigger's 'Handbuch der Classischen Bibliographie,' Leipzig, 1834. The 'History of the Twelve Cæsars' was translated into English by Philemon Holland, fol., London, 1606. There are four other English translations, the last of which is by A. Thomson, 8vo., London, 1796, 'with annotations and a review of the government and literature of the different periods.' There are French, Dutch, German, Danish, Italian, and Spanish translations. There is also extant a small treatise 'On Distinguished Grammarians' by Suetonius; and another 'On Distinguished Rhetoricians,' consisting at present of only six chapters. Neither of these works is included in the catalogue of Suidas, unless they belonged to the work 'On the Stemma of Illustrious Romans,' which however, if we may judge from its title, would be a different kind of work. It has been conjectured that they formed part of a work 'De Viris Illustribus' (not the work extant under that title, which belongs to Aurelius Victor), on the model of which, Jerome says, in an epistle to Desiderius, that he himself wrote a treatise. There are also extant the following Lives by Suetonius: the Lives of Terence, Juvenal, Persius, Horace, Lucan, and the elder Pliny; the last is only a few lines. These Lives are conjectured to have been part of a larger work 'On Poets.' But the Life of the elder Pliny would not properly belong to such a treatise.

SUETONIUS, PAULLI'NUS. [ATLAS; BOADICEA; BRITANNIA.]

SUEUR, EUSTACHE LE, one of the most celebrated of the French painters, was born in 1617. His father was an obscure sculptor of Mont Didier. After he had learnt from his father the first rudiments of design, he was placed in the school of Simon Vouet at Paris, then very famous, where he was the fellow-scholar of Le Brun and Mignard. Le Sueur soon surpassed his master, and forsook his manner, and by assiduously studying the antique, and some of Raphael's pictures and the prints after him by Marcantonio, he adopted a style, which for its simplicity and severity contrasted greatly with that of Vouet and the French school of the time, and has at length placed the name of Le Sueur deservedly above that of any of his rivals. He has been termed by his admirers the French Raphael; and although he was far behind that great master in every respect, even in colouring, yet he perhaps approached him more nearly in the style of his heads and draperies, and in the general character of his compositions, than any of his Italian imitators.

The celebrated series of St. Bruno, of twenty-two large pictures, painted on wood, in the cloister of the Carthusians at Paris, was executed by Le Sueur before his thirtieth year; he completed it in three years, and was assisted only by his brother-in-law and scholar Goussé, or Goulai, in the figures, and by Patel in the landscapes. In 1766 these pictures were transferred to canvas, and are now in the Louvre. The character and the composition of several of them are admirable, but in chiaroscuro they are very indifferent, and the colouring is monotonous: they have been engraved by Chauveau and Le Clerc. In his thirty-second year, in 1649, he painted his celebrated picture of St. Paul preaching at Ephesus, and the Gentiles burning their proscribed Books, for the guild of the goldsmiths, to be presented to the cathedral of Notre Dame; it is a grand composition of many figures, the heads and the draperies are much in the style of Raphael: it has been engraved by Stephen Picart and R. U. Massard. Paul Healing the Sick, engraved by Bauzo and the elder Massard, and the Martyrdoms of St. Laurence and of St. Protais, both engraved by Gerard Audran, are also admirable compositions, conspicuous for their simplicity and severity. Le Sueur painted many other celebrated pictures, as, Christ scourged; Christ with Martha and Mary; and the Presentation in the Temple; the histories of St. Martin and St. Benedict; and others—all of which have been engraved by the best French artists. His most extensive works however, by some considered his best, and which occupied him the last nine years of his life, were the mythological paintings of the Hôtel du Châtelet, executed for the President Lambert de Thorigny: they were removed to the Louvre in 1795. The palace was decorated by Le Sueur and Le Brun conjointly; three apartments were painted by Le Sueur, the 'Salon de l'Amour,' the 'Cabinet des Muses,' and 'l'Appartement des Bains.' In these paintings Le Sueur has still adhered to his great model, and has imitated the style of the celebrated series of the story of Cupid and Psyche, painted by Raphael, in the Farnesina at Rome. In the first apartment, he painted several beautiful compositions from the life of

Cupid; in the second, the Muses, and a grand composition of many figures, of Phaeton entreating Apollo to allow him to drive the chariot of the Sun; in the third, Diana surprised by Actæon, Diana detecting the pregnancy of Calisto, and the triumphs of Neptune and of Amphitrite. These works have been universally preferred to those of Le Brun; they have been engraved by Bernard Picart and others, in nineteen plates, and were published in Paris, in 1640, in folio, under the title 'Les Peintures de Charles Le Brun et d'Eustache le Sueur qui sont dans l'Hôtel du Chastelet, cy devant la Maison du Président Lambert, dessinées par Bernard Picart, et gravées tant par lui que par différens Graveurs.'

In 1655 Le Sueur's labours were terminated by his death, in the thirty-eighth year of his age; a constant excitement and an excessive application proved too much for a constitution naturally weak. Though he is reported to have been of a gentle and an amiable disposition, he had many enemies, but the report of his having been poisoned is without foundation; to be disliked by rivals, is the common lot of all men of extraordinary abilities. That Le Sueur's great talents engendered an active jealousy among his rivals, is generally allowed, especially upon the part of Le Brun, who is said to have openly expressed his satisfaction at the death of Le Sueur, saying, that he had been relieved of a great thorn from his foot. It cannot be doubted, that if Le Sueur had lived, the rising influence of Le Brun would have been seriously checked, and the French school of painting have taken ultimately a totally different course from that which it has pursued from the time of Louis XIV. until very late years. Although Le Sueur is now generally acknowledged to have been a great painter, during his lifetime his talents were never duly appreciated, nor was he ever employed on any public work; and though he was greatly superior to his more successful rivals, he would certainly have been a much greater painter had he had equal advantages with them. He never left Paris, he married very young, and being very badly paid for his works, he never had the means of travelling, or improving his taste by visiting Italy and studying the great works of its famous schools, or he would otherwise most probably have ranked with the greatest masters of Florence or of Rome. The defects of his style are, a deficiency in a thorough mastery of the naked figure, a feeble chiaroscuro, and a heavy and monotonous tone of colouring; some of his figures also want life, and appear to want purpose; in composition however, in character, and in the casting of draperies, he has seldom been surpassed; qualities foremost among the properties requisite to constitute a great painter.

When the Royal Academy of the Fine Arts was established in Paris, in 1648, Le Sueur was appointed one of the twelve antients or professors; he had been previously elected a member of the Academy of St. Luke at Rome. His style had no influence upon the arts in Paris; his only scholars were his three brothers, Pierre, Philippe, and Antoine Le Sueur, Le Fevre, and Nicolas Colombel. His own portrait, painted by himself, has been engraved by C. N. Cochin. In Landon's 'Ouvres de Le Sueur' there are 110 prints from his works.

(Felibien, *Entretiens sur les Vies et sur les Ouvrages des plus excellens Peintres, &c.*; D'Argenville, *Abrégé de la Vie des plus fameux Peintres*; Réveil and Duchesne, *Musée de Peinture et de Sculpture.*)

SUEZ, ISTHMUS OF, connects Africa with Asia, and separates the Mediterranean from the Red Sea. Its extent from north to south a little exceeds seventy-two miles. The most northern recess of the harbour of Suez, on the Red Sea, is hardly a mile south of 30° N. lat., and the village of Tyneh, on the Mediterranean, near the arm of the Nile, which in antient times was called the Pelusiac, and which at present is blocked up with sand, is only about two miles north of 31° N. lat. The advantages which would accrue to the commercial intercourse between Europe and the southern and eastern countries of Asia, from a canal navigable for large vessels being made across this isthmus, ...us, and it has been attempted several times. There ...e existed a canal on the isthmus, for numerous ...till appear in several places; it did not however ...vo seas, but only the Red Sea with the river ...anal was commenced when Egypt was an independent ...dom, under Necho, nearly 2500 years ago, and ...d by Darius. (Herod, ii. 157.) When the French, ...parte, had got possession of the country, they intended to give another direction to the commerce of Europe with India, by making a canal fit for large vessels across the isthmus; and accordingly they examined, with great care, the whole country between the two seas. A few years ago the idea was started of connecting the two seas by a railroad, and a company was formed in England for that purpose, but little or no progress seems to have been made in the execution of this scheme. The country does not present invincible obstacles to such an enterprise, as the following description, which is founded on the labours of the French engineers, clearly shows:—

one species ap... the accessory ... about four lines ... seas and those ... various fishes.

* Previously

The whole tract, from Suez to Tyneh, is uninhabited. and, in its present state, is uninhabitable. Drinkable water occurs only in one or two places, but as water has lately been found, by boring at the base of the mountains which lie to the west of the isthmus, and at no great distance from it, this inconvenience could be remedied by a short aqueduct from the wells to the line. It is very improbable that a canal could be made, owing to the want of water. The Red Sea is nearly thirty-three feet higher than the Mediterranean, and a canal would require locks; but the water of the whole isthmus would not be sufficient to feed one lock for a single day. A railway however could certainly be executed, as there is not one eminence along the whole line which deserves the name of a hill. The surface, in general, consists of sandstone, which in many places, by disintegration, has been converted into sand. The surface is not a level plain, but is interrupted by some considerable depressions, and these are covered with salt swamps or salt lakes. A depression of a somewhat different kind extends across the isthmus from Suez to Tyneh, not in a straight line, but diverging first to the west, and afterwards returning to the east, until it again reaches the straight line. In the southern part of this depression the canal of Necho had been made, and the French executed their levellings in the deepest part of it. By this levelling it was discovered that the depression, in nearly its whole extent, is lower than the level of the Red Sea. It is only the most southern extremity, between the arsenal in the harbour of Suez and the caravan-road leading from Cairo to Suez, a distance of 4½ English miles, which is higher than the level of the Red Sea at spring-tides, and in no part more than seven feet, though generally much less. The canal of Necho may easily be traced through this higher ground, and even where the country sinks below the level of the Red Sea such traces may be discovered as far as 30° 10′ N. lat., where they are lost in the deeper depression, which is filled by lakes, called the Bitter Lakes, from the taste of their waters. Up to these lakes the direction of the depression is due north, or nearly so, but the lakes themselves turn to the north-west, and extend to 30° 30′ N. lat. without interruption. The surface of the southern parts of the lakes is about 35 English feet below the level of the Red Sea, but in the northern parts a point was found which was 64 English feet below it. Not far from the northern extremity of the Bitter Lakes are the ruins of a temple of Serapis. The site of those ruins is less than two French feet below the Red Sea. At a short distance to the north of these ruins is another depression, containing a small lake called Temsah, which is dry during the greater part of the year, but filled with water when the inundations of the Nile have attained their greatest height. The water of the river reaches the lake by a depression in the stony ground, which bears the name of El Wadi. It is very narrow near the lake, but widens in proceeding westward to nearly a quarter of a mile, until, in approaching the small lake called Berket-el-Serigeh, it reaches the inhabited parts of the delta, and is nearly half a mile wide. Throughout this depression, which in some parts is nearly twenty French feet below the level of the Red Sea, the canal of Necho had been led, as appears from the numerous traces which still exist. In proceeding northward of Lake Temsah, and at no great distance from them, are some salt-marshes called Karfeh, which occupy a space of a few miles in length from north to south. West of these marshes the stony ground in some places was above the level of the Red Sea, and in others sinks some feet below it. Between the salt-marshes and the lake of Bellah is a similar stony country, of about the same elevation. The last-mentioned lake may be considered as the most southern branch of Lake Menzaleh, being united to it by low ground and marshes, which during the inundations of the Nile are covered with water. East of these two lakes is a stony

uneven tract, the surface of which never attains the elevation of the Red Sea, and this tract extends to 31° N. lat., where it joins the plain of Pelusium, which is nearly thirty feet below the spring-tides of the Red Sea, and about three feet above the level of the Mediterranean. The plain is a dead flat, with a sandy arid soil, almost entirely destitute of vegetation, and in many parts covered with a thin layer of salt. When the water attains its greatest height in the Nile, it is almost entirely inundated. At the eastern extremity of the plain is the small village of Tyneh, and about a mile to the south-west of it are a few ruins, which are supposed to be those of the antient town of Pelusium. But no traces of the bed of that arm of the Nile, the Pelusiac, the name of which was derived from that town, can be discovered in any part of the plain. The country which extends to the west of the line described is covered with horizontal strata of sandstone, and presents few inequalities, except towards the south, where, at the distance of about four miles from it, and south of 30° 20′, are the extremities of the ridges which lie between Cairo and Suez, and bear the names of Jebel Amed Taber, Jebel Ueybe, and Jebel Autad: an elevated hill, probably connected with Jebel Ueybe, occurs at a short distance from the western margin of the Bitter Lakes, and is the highest point of the isthmus. The country which lies to the east of the line is stony as far south as the south end of the Lake of Bellah on the north, and as far north as the caravan-road from Cairo to Suez on the south, but that part of the country which intervenes between these two points is entirely covered with sand.

SUEZ, a town situated at the head of the westernmost of the two arms or 'gulfs' in which the Red Sea terminates, is in 29° 57′ 30″ N. lat., 32° 31′ 33″ E. long., and 62½ geographical miles east from Cairo. Suez is situated on an angle of land between the broad head of the gulf, the shore of which here runs nearly from east to west, and the narrow arm which runs up northward from the eastern corner of the gulf. It is poorly walled on three sides, being open to the sea on the north-east, where is the harbour and a good quay. Within the walls are many open places, and several khans built around large courts. The houses are in general poorly built. There is a bazaar, or street of shops, tolerably furnished with goods from Cairo. The inhabitants are about 1200 Moslems and 150 Christians of the Greek church. The importance of Suez however arises from its position rather than its population, which can never be great. The transit of the productions and merchandise of the east from the Red Sea to the Nile has always made this an important station, and caused the existence of a city in the vicinity, though Suez itself as a town cannot be traced to an earlier origin than the early part of the sixteenth century. The concourse of pilgrims who annually embark here for Mecca has also rendered necessary a town at this station. The present arrangements for making it the point of communication between Europe and India, by means of steam-navigation on the Red Sea, may probably give an impulse to its prosperity and enlarge its population; but from the want of fresh water, and of every kind of verdure and cultivation, it can never become more than a place of passage, which both the traveller and the inhabitant will hasten to leave as soon as possible.

(Robinson's *Biblical Researches in Palestine:* Niebuhr's *Reisebeschreibung;* Burckhardt's *Travels in Syria, &c.*)

SUFFERANCE. [TENANT.]

SUFFICIENT REASON. (Mathematics and Physics.) The principle which is connected with these words might be, and frequently is, called the *want* of sufficient reason; and even this term may appear inaccurate, for it should be the want of *any possible amount* of reason. Since however all that takes place must have a sufficient reason (whether we know it or not) for its happening, and everything which is asserted must be capable, if true, of being shown to have a sufficient reason, there is no objection to our using the words 'want of sufficient reason' in the sense of absolute want of reason, in all matters connected with the exact sciences. If A be equal to B, there must not only be reason, but reason enough for it; anything short of reason enough is no reason at all, and anything short of proof enough is no proof at all.

The use of the word reason in the statement of this principle may itself be fairly objected to. We are in the habit of speaking of mathematical consequences in the same manner as of those to which the notion of cause and effect applies. When one proposition is made to subserve the proof of another, we call the first one of the reasons of the second, just as we should say that the reason of a flood was the preceding heavy rain. But this mode of speaking must be objectionable if the word reason be used in the same sense in both places. For, first, we are at liberty to deny the effect on denying that cause; if the rain had not fallen, the flood would not have taken place. But when we say that one mathematical proposition is the reason of another, in which position do we stand if we make an hypothetical denial of the first? Simply in that of persons who assert a contradiction of terms, and try to make rational consequences. Thus, the equality of the angles at the base of an isosceles triangle is one of the reasons (so called) why the tangent of a circle is at right angles to the radius; rationally, the first is one of the simpler propositions, the necessity of which, when seen, helps us to see the necessity of the second and more complicated one. But the necessity of the first is not previous to that of the second, except in the order of our perceptions, when we follow Euclid. Suppose we were to ask, if the angles at the base of the isosceles triangle had not been equal, what effect would that circumstance have had upon the position of the tangent of a circle? We might as well inquire, what would our geometry have been if two straight lines had been capable of inclosing a space? We remember a book of arithmetic in which it was gravely asked, by way of exercise for the student, 'If 6 had been the third part of 12, what would the quarter of 18 have been?' a question which can only be paralleled by 'If a thing were both to exist and not to exist at one and the same moment, how many other non-existences would therefore become existences?'

Secondly, the term reason, in the sense of previous cause, is wrong as applied to mathematical propositions, because when any one is made to prove the second, it generally happens that the second, when granted, may be made to prove the first. Thus [RIGHT ANGLE] of the two propositions, 'all right angles are equal,' and 'two lines which coincide between two points, coincide beyond them,' one must be assumed, and the other will then follow: but either may be the one assumed; the other will follow. Now it is absurd to say that of two things each is the previous cause of the other. The whole of this confusion may be remedied by any one who will remember that one proposition is not the cause of another, but it is our perception of the one which is made the instrument of bringing about our perception of the other. The constitution of our faculties is the previous cause of the necessity of mathematical propositions, but not of one before another, though in arriving at the perception of this necessity our cognizance of the necessity of one is made the previous cause of that of the necessity of another. To say that B is the consequence of A, is only to say that our knowledge of the truth of B is the consequence of our knowledge of that of A.

Taking care to use the word reason in the sense just alluded to, we assume that whatever is necessary has a possibility of being shown to be necessary, and that whatever is true has a possibility of being shown to be true. If this be a legitimate assumption, it then follows that whatever it is impossible to show to be true, must be false. But can there be such a thing as a proposition of which there shall be seen not its falsehood, but the impossibility of demonstrating its truth? Can there arise a case in which we shall be so completely cognizant of all that may possibly be said for or against an assertion, as to affirm a necessary incapability of demonstration of one side or the other? Such cases are universally admitted by mathematicians to exist; and the final assertion which is made on the known impossibility of proving a contradiction, is said to be made on the principle of the *want of sufficient reason.* But this very dangerous weapon is never put into the hands of a beginner, in mathematics at least. And when we call it a dangerous weapon, we do not deny its utility, but we only state what is well known to every mathematical teacher, that a student who is allowed to proceed one step by this principle will soon ask permission to make it the universal solvent of difficulties, and will be quite ready to urge that a proposition *cannot be shown to be false,* in preference to seeking for or following the demonstration that it *is true.* A beginner can easily admit a sound use of this principle, but can hardly distinguish it from the thousand inaccurate applications which his ignorance will make, if it be left in his own hands.

But we can imagine we hear it said that this principle,

though sometimes employed in pure physics, is never introduced into mathematical reasoning except *after direct demonstration*, in order to confirm the mind of the learner by making him see how difficult it would have been to imagine the possibility of any contradiction being successfully maintained against the proposition *just proved*. We believe indeed that this principle is seldom employed, and always without necessity, so that we could wish its use were entirely abandoned. But we can show that a tacit appeal to it is sometimes made; and this is the worst possible mode of employing it. If the principle be dangerous, and liable to be unsoundly used, it should be most carefully stated when it is used. Whenever we see a proposition assumed, not as an express postulate, but in a definition for instance, or as a self-evident truth, we may trace the operation of this principle on our minds. For instance, take the proposition which is, if there be such a thing in any one proposition, a digest of all the methods of mathematics, namely, that if the same operations be performed on equal magnitudes, the resulting magnitudes are equal. Try to imagine this not true, and want of sufficient reason interferes to prevent success. *What can make a difference?* In this question the principle claims to be applied.

Now, first, in examining the definitions of Euclid, we find an assertion of theorems which we can hardly suppose that Euclid overlooked, though it is very possible that the impossibility of imagining otherwise may have been his guide. For instance, the assertion of the equality of the two parts into which a diameter divides a circle, following immediately upon the definition of a circle; and the definition of equal solids as those which are contained by the same number of plane figures equal each to each. These and such little matters have been, or may be, corrected; but we will now point out a use of the principle which exists in our elementary works of the present day in an unacknowledged form.

In proving the celebrated proposition of Albert Girard relative to the dependence of the area of a spherical triangle upon the sum of its angles, it is assumed that two spherical triangles which have their sides and angles equal, each to each, are equal in area. Now it is easily shown [SYMMETRY] that there may be two such triangles of which it is impossible to make one coincide with the other, nor is any process ever given for dividing each into parts, so that the parts of one may be capable of coinciding with those of the other. Let the angular points of one be placed upon the angular points of the other (which is always possible), and the triangles will not coincide: in common language, they will *bulge* in different directions. When the triangles are so placed, and the common chords drawn, there is no difficulty in seeing that if ever a want of sufficient reason can be granted upon perception, it is for there being any inequality of the areas of the two triangles. And the equality of these areas is accordingly assumed: for instance, in the proposition above alluded to, a pair of unsymmetrically equal triangles always occurs, except when the given triangle is isosceles. Here again the appeal to this principle may be avoided; for it is easy to make the given triangles into the sum or difference of isosceles triangles, in which each of one set is capable of being actually applied to one of the other.

Leaving the subject of pure mathematics, let us now consider the application of this principle in physics. We have observed [STATICS] that the line of separation between pure mathematics and the more exact parts of mathematical physics is very slight indeed: this means as to the clearness and fewness of the first principles, and the rigour of the demonstrations. If we cut the link which ties the sciences of statics and dynamics to the properties of the matter which actually exists around us, we may go farther, and say that we have not only pure sciences, but pure sciences in which the principle of the want of sufficient reason is strictly applicable, because it is our own selves who have, by express hypothesis, excluded sufficient reason. In propositions of pure mathematics, we have seen that we cannot invent or deny for any hypothetical purpose; *is* and *must be*, *is not* and *cannot be*, are synonymes, in all the truths which these sciences teach. But the properties of matter which are not also those of space, are not, in our conceptions, necessary: we can imagine them other than they are, without any contradiction of ideas. We shall now proceed to consider the point mentioned in STATICS, namely, the character of the axioms of that science. Are they 'self-evidently true,' and 'not to be learnt from without, but from within?' We will not here inquire whether the first must be the second, not being sufficiently clear as to what is meant by knowledge 'from without' and knowledge 'from within' to enter upon any such investigation. It will do for our purpose to take knowledge 'from within' to be a phrase descriptive of such truths as that two straight lines cannot inclose a space, and knowledge 'from without' another phrase indicating such truths as are found, say in the facts of political history or geography. Let us separate from the rest one axiom of statics, say 'equal weights at the ends of equal arms of a horizontal straight lever balance one another.' First, 'equal weights' is a synonyme for equal and parallel pressures. We have no objection to placing the idea of pressure on the same footing as that of a straight line, for be the name we give the former conception what it may, it is probable that those powers of communication with the external world which are certainly necessary to the development, at least, of the former, are not less necessary to that of the latter. Nor are equal pressures difficult of definition; let them be those which are interchangeable, so that either may be put in the place of the other. The rest of the terms of the axiom are geometrical, and to balance each other is to produce no motion,—motion, independently of producing causes, being, we think, as much an idea of geometry as any other. Let A and B be the two ends of the lever (a rigid bar without weight), and C its middle point, which is the pivot; that is to say, the middle point cannot move, the only possible motion of the lever being revolution, in the plane of the pressures, about that middle point. On these hypotheses, we may certainly say that the axiom is self-evident, for want of sufficient reason, that is, of a possibility of sufficient reason for anything in contradiction of it. We have, before the pressures are applied, no cause of motion, by hypothesis: we are to conceive a lever which, if it move at all, does so by reason of the pressures. We have made these pressures equal, and applied them symmetrically: there is then, and can be, no reason why one should predominate, which does not hold as much of the other. In the very notion of equality of pressures there is interchangeability; that is, each may be substituted for the other without alteration of effect. Suppose then the left-hand pressure to predominate: it will do so if the pressures be interchanged. But after the interchange, the same reasons which made the left hand predominate will make the right hand predominate: or both ends will move in the direction of the pressures, which is impossible.

We believe the preceding to be as legitimate a use as can be made of the sufficient-reason principle: but before statics can be established on axioms, there is another of them required, which we have never been able to satisfy ourselves comes 'from within.' It must be assumed that the pressure on the pivot is equal to the sum of the pressures on the ends, whatever the length of the arms may be: this we believe *we learn* from existing matter in quite a different sense from that in which we speak when we say that we learn the conception of pressure or of a straight line from our communication with the external world by our senses: to us it more resembles the assertion that the sea is salt, or that a horse has four legs. It certainly does not arise from the sufficient-reason principle; for there is a reason why difference of pressures on the pivots may arise in levers which only differ in the arms, namely, that very difference of the arms. In fact, there is a presumption against the truth of the proposition *à priori*, derived from a principle the frequent and usual truth of which may as well be called knowledge 'from within' as the conception of pressure or of a straight line: this principle is, 'differences generally make differences, but not necessarily.' The beginner in geometry has this in his mind when he feels that he has learnt something in finding out that the sum of the angles of a triangle is always the same, whatever the triangle may be: he would have expected it to be otherwise. Triangles of different sides have generally different areas, different perpendiculars, different inscribed and circumscribed circles, and different angles: why not different sums of angles? In truth it is a constant and latent assumption throughout the exact sciences that 'differences are to be supposed to make differences, except where the contrary is proved.' And the assumption that the pressure on the pivot of a lever is independent of the arms, is either in defiance of this general principle, or a result of experience.

Thinking then that the sciences of pure mechanics can be founded upon few and incontrovertible postulates, in such

a manner as to entitle them to the name of pure sciences, or some other which shall mark the real distinction between them and the other sciences of matter, we cannot yet be of opinion that their postulates are all derived from their own evidence, or obtainable from the sufficient-reason principle. There are however many points connected with this part of them which are difficult of exposition for want of acknowledged terms.

SUFFIX, a term lately employed in mathematical language to denote the indices which are written under letters, as in a_0, a_1, a_2, a_3, &c. Though these signs have been so long used, we never saw a distinctive name given to them before the publication of Professor Hall's Differential Calculus.

SUFFOLK, a maritime county of England, on the east coast. It is bounded on the north by the county of Norfolk, from which it is in almost every part separated by the rivers Little Ouse, Waveney, and Yare; on the east by the German Ocean; on the south by the county of Essex, from which it is in almost every part separated by the river Stour; and on the west by Cambridgeshire, from which it is, for a short distance, separated by the river Lark, a feeder of the Great Ouse. The general form of the county approximates to that of a crescent, of which the whole of the concave side is conterminous with the county of Norfolk. The approximation to the crescent shape would be greater but for the elongation of the south-western part about Haverhill, where the boundary forms an acute angle, and for a second projecting portion near Newmarket. The greatest length is from north east to south-west, from Southtown, a suburb of Great Yarmouth, to the neighbourhood of Haverhill, 68 miles; the greatest breadth, nearly at right angles to the length, is from the bank of the Little Ouse, in the north-west corner of the county, to Landguard Fort, opposite Harwich, 52 miles. The area of the county is estimated at 1515 square miles, or, taking the aggregate of the parochial surveys, 918,760 acres; the population, at the different enumerations, from 1801 to 1841, was as follows:—1801, 210,431; 1811, 234,211, increase 11 per cent.; 1821, 270,542, increase 15 per cent.; 1831, 296,317, increase 9 per cent.; 1841, 315,129, increase 6·3 per cent. The census of 1831 (which we retain to facilitate comparison with other counties, in which we have employed it) gave 196 inhabitants to a square mile. This county is in size the twelfth of English counties, being smaller than Cumberland, but larger than Sussex; in amount of population (1831) it was the seventeenth, its place being below Cornwall, but above Sussex; and in density of population the twenty-third, falling short of Monmouthshire, but exceeding Hampshire in this respect. There are two county-towns. Ipswich is 63 miles in a direct line north-east of the General Post-office, London, or 70 miles by the mail-road through Romford, Chelmsford, Witham, and Colchester; Bury St. Edmunds is 62 miles in a direct line, north-east by north, from the same point, or 76 by the mail-road through Bishop's Stortford and Newmarket. The county is included between 51° 55′ and 52° 38′ N. lat., and 22′ and 1° 46′ E. long.

Surface; Coast-Line; Geology.—The surface of this county is gently undulating, except just along the north-western and some parts of the north-eastern border, where the land subsides into a marshy flat, secured from overflow only by embanking the course of the rivers. There are also some marshes bordering the rivers in the south-eastern part, but none of these are of any extent. There is not an eminence in the county worthy of notice. The highest ground, as determined by the course of the waters, forms a ridge of crescent-like shape, corresponding with that of the county, through the centre of which it extends. It may be indicated by a line drawn from the neighbourhood of Lowestoffe in the north-east, between Bungay and Halesworth, to the neighbourhood of Debenham; and from thence to the western border of the county, passing between Stowmarket and Ixworth, between Bury and Lavenham, and between Newmarket and Clare. The waters which flow northward from this line fall into the Waveney or the Ouse; while those which flow southward join the Stour, the Orwell, the Deben, or other streams flowing into the German Ocean.

The coast has a tolerably regular outline, convex to the sea. The bays are shallow, and the headlands have little prominence. The maps notice three bays: Hollesley Bay, between the point at Bowdsey, near the mouth of the Deben and Orford Ness; Aldeburgh or Aldborough Bay, between Orford Ness and the headland near the village of Thorpe; and Southwold or Sole Bay, between Thorpe Point and Easton Ness, north of Southwold. This last has some historical interest as the scene of a severe but indecisive conflict between the Dutch and English fleets (A.D 1672). The headlands are the point on which Landguard Fort is placed, at the entrance of the æstuary of the Orwell and the Stour, opposite Harwich; the point at Bowdsey; Orford Ness, near Orford; the point near Thorpe; Easton Ness; and Lowestoffe Ness, the most easterly point in Great Britain. The harbours are the æstuaries of the rivers Stour and Orwell, Deben, Butley or Alde, Blyth and Yare, and the artificial cut through lake Lothing into the Waveney. The æstuary of the Stour and the Orwell is for the most part lined with marshes, which however do not in any part extend more than a quarter of a mile inland from the banks of those rivers, except just above Landguard Fort.

The sea-shore from Landguard Fort is lined for about two miles with sand-hills, and from thence for two miles, nearly to the æstuary of the Deben, by low cliffs of crag upon blue clay. Beyond the æstuary of the Deben (which is skirted by a narrow line of marsh-land) cliffs of similar formation to those just mentioned recommence, and extend nearly three miles to the point at Bowdsey. The shore of Hollesley Bay, from the point at Bowdsey to Orford Ness, eight miles, is low, lined as far as the æstuary of the Butley or Alde with marshes, and north of that æstuary by beach or shingle, which continues to line Aldeburgh Bay, as far as the town of Aldeburgh, four miles, and separates from the sea the marshes formed by the Alde, which has the lower part of its course parallel to the coast-line, and very near it. From Aldeburgh the coast continues to be low for seven miles, and then rises into cliffs, near Dunwich, of rounded shingle and sand. These cliffs extend about two miles to Dunwich, where the low shore recommences, and extends four miles to Southwold. From Southwold, with two or three short intervals, in which the shore is low, a line of cliffs, consisting for the most part of sand or chalk rubble covering gravel and red loam, extends eighteen or nineteen miles to the mouth of the Yare, where the coast of the county terminates. The whole length of the coast may be estimated at above fifty miles.

The greater part of the county is covered by diluvial beds. The exceptions are the crag and London clay district of the south-east, and the chalk district of the north-west. The crag and London clay district may be considered as bounded by a line drawn from Orford by Woodbridge and Ipswich to the banks of the Stour, between Sudbury and Nayland. The chalk is all found to the north-west of a line drawn from Euston, near Thetford, to Bury St. Edmunds, and from thence west by south to the border of the county. The chalk does not wholly occupy this district, but rises from beneath the diluvial beds, or from beneath the fens which occupy the north-western extremity of the county. These diluvial beds vary in their character. In the centre of the county, between a line drawn through Sudbury, Lavenham, Stow-Market, and Diss (in Norfolk), on the west, and another line drawn through Ipswich, Debenham, and Harleston (in Norfolk), on the east, they consist of beds of clay, with fragments of chalk. Eastward of this, beds of loam, with fragments of chalk, extend nearly to the shore, along which they are, in many parts, covered with sand, or gravel, or shingle, or chalk rubble. A similar loam is found bordering the clay on the west side for some distance, and extending south-west of Bury St. Edmunds to the very border of the county. Beyond this, on the north-west, are found beds of sand, with or without flint gravel.

The crag formation consists chiefly of thin layers of quartzose sand and comminuted shells, resting sometimes on chalk, sometimes on the London clay. Crag is a local name for gravel. Close examination has led to the subdivision of this deposit into the red crag and the coralline crag, the former being uppermost when the two are found together. The red crag is at once distinguishable from the coralline by the deep red ferruginous or ochreous colour of its sands and fossils. The fossil testacea found in the crag, amounting to upwards of 400 species, are some of them common to both divisions; others are peculiar to one division, and characteristic of it. These fossils bear a general analogy to testaceous animals now existing in the northern seas, between lat. 50° and 60°; but whether any are identical with those now found in the adjacent (German) ocean is matter of dispute. Lyell refers the crag formations to the Older Pliocene period. The thickness of the crag is not

known: it has been penetrated 50 feet near Orford without reaching the bottom.

It is probable that the London clay occupies the whole district which we have assigned to it and the crag; and that the latter covers it in that part of the district which lies north-east of the Orwell. That part of the district which lies between the Orwell and the Stour is for the most part occupied by the London clay alone.

The chalk of the north-western side of the county does not rise into high hills; the formation appears to extend under the diluvial beds which occupy the centre of the county. (Conybeare and Phillips's *Outlines of the Geology of England and Wales*; Lyell's *Elements of Geology*.)

Suffolk produces scarcely any minerals of value. Clay and shell-marl from the crag formation have been dug for manures.

Hydrography and Communications.—The Waveney and the Little Ouse, border rivers, which separate this county from Norfolk, and receive the drainage of the northern part, are described elsewhere [NORFOLK, vol. xvi., p. 258-9]: where also the navigable cut from the sea, through lake Lothing, is described, though it belongs to Suffolk. The tributaries of the Waveney are all small. The longest, which rises about two miles east of the village of Mendlesham, and flows by the borough of Eye into the Waveney at Hoxne, is only 10 or 12 miles long. In that part of the county which is adjacent to the lower part of the course of the Waveney are several small sheets of water, as Oulton Broad and lake Lothing, through which the navigable cut passes, and which, together, are above two miles long from east to west; Breydon Water, above three miles long, just below the junction of the Waveney and the Yare, on the border of the county; Fritton decoy, a winding sheet above two miles long; and Flixton decoy, which is much smaller. None of these pieces of water have much breadth, except Breydon, and that, in its widest part, is not a mile across.

The Little Ouse receives only one stream which requires notice. It rises near Bradfield St. Clare, about five miles south-east of Bury St. Edmunds, and flows by Ixworth and Euston park into the Little Ouse above Thetford. Its length may be estimated at 16 or 18 miles. The river Lark, a tributary of the Greater Ouse, rises at Lawshall, five or six miles south of Bury St. Edmunds, flows northward to that town, where it receives a little stream called the Linnet, and then flows north-west, by Mildenhall, to the border of the county, which it skirts for a few miles, and then enters Cambridgeshire, where it joins the Greater Ouse. Its whole length may be estimated at about 30 miles. It is navigable from Bury, and serves to convey produce from that town and neighbourhood to the river Ouse and the port of Lynn.

Of the streams which drain the southern part of the county, the Stour is the most important. It divides Suffolk from Essex, and is described elsewhere. [ESSEX, vol. x., p. 17.] The Stour receives many tributaries: a stream 10 miles long from the neighbourhood of the village of Wickham Brook, and another rather longer from the village of Reed, join it near Long Melford, a little above Sudbury; and the Bret, 23 miles long, from Thorpe Green, near the village of Thorpe Morieux, flows first south-east and then south by Lavenham and Hadleigh into the Stour near Stratford, on the road between Colchester and Ipswich. None of these tributaries are navigable.

The Orwell, or Gipping, as it is called in the upper part of its course, is formed by the junction of several streams, which unite just by Stow-Market, and flows south-east by Needham-Market to Ipswich. Below that town it expands into an æstuary of considerable width, which unites at Harwich with the æstuary of the Stour. It is the æstuary alone which bears the name of Orwell. The course of this river to Ipswich is above 20 miles, for more than half of which (viz. from Stow-Market) it is navigable: the æstuary is 10 or 12 miles long, and for the greater part of that distance more than half a mile wide at high-water. Sea-borne vessels of considerable burden get up to Ipswich. Ipswich, antiently written Gypeswic, Gippeswic, Gipeswich, and Ypeswich, obviously includes in its name the same element as the name Gipping.

The Deben rises near Debenham, and flows about 20 miles in a winding course to Woodbridge, below which it becomes an æstuary 9 or 10 miles long, and from a quarter to half a mile wide, navigable for sea-borne vessels of considerable burden.

The Alde rises near the village of Brundish, and runs 11 miles south-east to its junction with the Ore, which rises near Framlingham, and has an eastward course of about 12 miles. From the junction the united stream, which is sometimes called Ore, sometimes Alde, flows about 15 miles into the sea. The course of this part of the river (which is, for the greater part of its length, an æstuary) is remarkable: about eight miles below the junction of the Alde and the Ore, near the town of Aldeburgh, it approaches within 200 yards of the sea; and then turning suddenly, has the rest of its course nearly parallel to the shore, from which it is separated by a long, narrow, marshy peninsula. The principal feeder of the Alde is the Butley, a small river, the lower part of which becomes a tolerably wide æstuary, opening into the æstuary of the Alde just before it joins the sea. The Alde is navigable to Snape Bridge, near the head of the tideway. The part below the junction of the Butley is sometimes called Butley.

The Blyth rises near Laxfield, and flows eastward 16 miles by the neighbourhood of Halesworth, from which town it receives a small feeder, into the sea near Southwold: it is navigable up to Halesworth, eight or nine miles.

There are no canals, but some of the smaller rivers have been made navigable.

The Norwich and Ipswich mail-road enters the county at Stratford Bridge over the Stour, between Colchester and Ipswich, and runs to Ipswich, and from thence northward by Stoke and Scole Bridge over the Waveney into the county of Norfolk. It is remarkable that this road does not pass through a single market-town between Ipswich and Norwich, a distance of 43 miles, though passing through a fertile and cultivated country. The Yarmouth mail-road branches from the Norwich road at Ipswich, and runs through Woodbridge, Saxmundham, and Lowestoffe. A second Yarmouth road branching from this at Blythburg, between Saxmundham and Lowestoffe, passes through Beccles, and rejoins the mail-road just before entering Yarmouth. The Norwich and Newmarket mail-road enters the county at Newmarket, runs eastward to Bury St. Edmunds, and then northward to Thetford in Norfolk. The distance to Norwich is lessened by following the road which leads from Newmarket to Thetford through Barton Mills. Another road to Norwich enters the county at Sudbury, and runs by Long Melford to Bury, and from thence by Ixworth and Botesdale to the Norwich and Ipswich mail-road at Scole. A road from Bury leads by Stow-Market and Needham-Market to Ipswich. The roads in all parts of the county are excellent.

The Eastern Counties Railway will cross the county in nearly the same direction as the Norwich and Ipswich mail-road, and not far from it. It runs for the most part on the east or right side of the road, at a distance varying from a quarter of a mile to four miles.

Agriculture.—The county of Suffolk is peculiarly interesting in an agricultural point of view; and, with the adjoining counties of Norfolk and Essex, it forms one of the best cultivated districts in the southern part of Great Britain.

The climate is much drier than that of the more western counties of England; but also colder in spring, when the north-easterly winds prevail. The only inconvenience arising from this is the occasional freezing of the turnips, when left on the ground; but the beneficial effects of a sharp dry air on the land, which has been ploughed up before winter, fully compensate for the occasional loss of turnips and the slow progress of early feed. The soil, although varying extremely, may be divided into three or four distinct kinds. A very rich loam, chiefly alluvial, is found in a small portion of the southern part of the county, between the Orwell and the Stour, both of which rivers form æstuaries at their junction with the sea at Harwich. This loam is not so compact as clay, nor so loose as sand, but contains a great proportion of organic matter, or whatever else constitutes a very fertile soil. Of this kind of soil it is supposed, in the Report made to the Board of Agriculture, that there may be about 46,000 acres. The next class consists of heavier loams, varying in every degree, but in general resting on an impervious soil of marl or clay, and in most situations requiring the assistance of drains to carry off superfluous water. This soil is found in the whole of the centre of the county, from the Stour to the borders of Norfolk, and is computed at 450,000 acres, being nearly half the surface of the whole county. Between the strong loam and the sea is a strip running from the north bank of the river Orwell to Yar-

mouth, diminishing in breadth as it stretches northward, and consisting chiefly of sand of various qualities, incumbent on a subsoil of crag, which is a loose rocky substance, composed of sand, gravel, and broken shells, partly consolidated into a kind of stone. Some of this sand is poor, and scarcely worth cultivating; but a great part of it is enriched by organic matter intimately mixed with it: this is excellent for roots, especially carrots, and bears very fine barley. In the portions which lie low, and which have at some time or other been covered with water, a very rich mud has been deposited, and has produced as rich a soil as may be desired. These rich portions however are few in comparison to the whole tract, which altogether contains about 150,000 acres. There is another tract of sand of a much inferior quality on the western extremity of the county, extending from Bury St. Edmunds to Thetford, with some better lands interspersed. This lies chiefly on a chalk bottom, and is scarcely thought worth cultivating. Where it has been improved, so as to become productive, it has been done at a very considerable expense in draining, trenching, and marling. There may be in this district about 100,000 acres of this poor sand, with 10,000 of a better quality. The last class consists of the fen-lands, which, when properly drained, become valuable; but in their natural state, soaked in water, they are of little value. The extent of fen is estimated at 30,000 acres.

The system of tillage is very uniform throughout the county. The greater part of the land is under the plough. There is now scarcely such a thing to be seen as a common field: a complete bar was formerly opposed to any improved mode of cultivation by the absurd rules and restrictions as to cropping which were established in consequence of the joint and several rights over the land, which no longer exist since the common fields have been divided and enclosed. The practice of ploughing the stubble immediately after harvest, and giving it the full benefit of the alternations of rain and frost which mark the variable climate of Great Britain and Ireland, is adopted on all kinds of soils. Wherever turnips can be profitably raised, and safely fed off with sheep, they form the basis of all rotations. Where the land is too strong and adhesive for turnips, and where sheep would do harm by their treading, and where the carts and horses would do equal damage in taking them off, a fallow is substituted: this however is not the old fallow preparatory to a crop of wheat, but it is the *long fallow*, in which the land is exposed to the influence of two winters. Barley and clover are sown in the spring of the second year, to be succeeded by wheat and beans. This long fallow has been mentioned before. [Essex, *Agriculture*.] We shall only observe that it was suggested by the failure of the turnips when it was attempted to sow them on very strong soils. To prevent the land being overrun with weeds, the natural concomitant of a failing crop, it was ploughed in summer and again in autumn; and as the sowing of wheat without any manure, and out of course, was not approved of, it was left to come in for barley with the lighter lands which had borne turnips. Much to the surprise of those who first adopted this plan, almost from necessity, they found that their barley was more abundant and of a better quality after the long fallow, *without manure*, than upon those fields which had borne turnips, and on which sheep had been folded. Nothing was lost therefore but the value of the turnips when fed off, which in many years is trifling. The clover ley being manured in the succeeding autumn, a good crop of wheat might be depended upon. Thus three valuable crops were reaped in four years, barley, clover, and wheat; and, where the land was in good heart, a crop of beans could be obtained, without risk, either after the clover or after the wheat, usually the latter, before another fallow, giving four crops in five years. We are not aware that this mode of cropping stiff clay-lands is adopted in any part of England, except the three counties of Essex, Suffolk, and Norfolk, and perhaps in a part of Cambridgeshire adjoining these counties; but all the practical farmers who have adopted it have found their advantage in continuing the long fallow on stubborn clays.

On turnip land the four-course shift, as it is called, is universal, with some deviation as to the recurrence of clover every fourth year, a portion of the land being laid down with grass-seeds or Italian rye-grass, or planted with beans or peas, according to the nature of the soil. The simple Norfolk rotation is however on the whole the most profitable, and by means of deep ploughing, which is but partially introduced, clover is found to succeed for a considerable period every fourth year. When any deficiency appears, recourse must be had to some substitute, so as to defer it to every sixth or eighth year. The subsoil plough is of great assistance in securing a crop of clover.

There is no part of England where the implements of husbandry are more perfect than in Suffolk, or where new implements are tried with more readiness and with less prejudice. This is owing in a great measure to the very excellent manufacturers of agricultural implements who live in the county. The competition among these men, many of whom possess great capital, tends to the detection of every defect, and ingenuity is stretched to make improvements both on the form and the durability of implements.

The ploughs almost universally used, whether with or without wheels, are of cast-iron, except the beam and the stilts; each part admits of separate renewal at a moderate expense, being cast on one pattern and attached with nuts and screws. The wheel-ploughs are preferred by the ploughmen, because they require less attention and are easier to hold; for a boy can hold a wheel-plough who would make but sorry work with the best swing-plough. The question of comparative draft, which is at this moment in dispute between the Royal Agricultural Society and the Highland Society of Scotland, it would be presumptuous to decide; but perhaps it will be found that in some cases wheels are convenient and save labour both to man and horse, while in others a good swing-plough in the hand of a skilful ploughman will plough a greater variety of land in a more complete manner, without any distress to the horses.

It would be superfluous to enumerate all the different improved instruments which are in use in a large Suffolk farm: it would comprise a complete catalogue of scufflers, scarifiers, rollers, and harrows, which assist the plough in preparing the land; of drilling-machines to deposit the seed; of threshing machines, winnowers, hummellers, &c. to prepare the grain for the market; of machines for cutting roots or straw, or bruising oil-cake for cattle, or bones for manuring the land. Nowhere is so great a variety of farm-machines used for saving labour.

Many of the farm-buildings which have been erected of late years are not only commodious, but splendid. On the older farms there may be some deficiency, but the habitations of the farmers in general are such as many squires of the last century would not have disdained to live in; many in fact are old mansions. The barns are not so large or so numerous as they used to be before the mode of stacking corn out of doors was so generally adopted. Where a threshing-machine is erected, a single floor is sufficient for a large farm; and if the bays will hold one stack at a time, there is stowage enough for corn. The yards, on the other hand, are much increased and better arranged; where there is not sufficient shelter by walls and sheds, this is supplied by what are called *halm-walls*. [Harvest.] The stubble (*halm*) which has been raked off the land after harvest, is stacked in the farm-yard in such a manner as to enclose a space, leaving an opening only sufficient to admit a loaded waggon. A small square is thus enclosed, and the cattle are sheltered from cold winds. The wall is made ten or twelve feet high, and ten or twelve feet wide at the bottom. This great width is necessary to resist high winds and the rubbing of the cattle. The top is roughly thatched. When, by the rubbing of the cattle and the decay of the stubble, the wall becomes loose and unsteady, it is taken down, and spread over the farm-yard as litter, and a new wall built. These halm-walls last several years. Nowhere are stacks of corn more neatly built than in Suffolk. As many as are intended to be kept for any length of time are built on frames, called *staddles*, supported by stone or iron pillars about eighteen inches from the ground, with flat caps over the pillars to prevent the access of rats and mice. The sides of the stacks are cut smooth by a sharp knife, such as is used for cutting trusses of hay, and thus the depredations of birds are prevented, and nothing is lost. When barley is stacked, which is generally on the ground in a dry spot, it is protected by a slight coat of thatch all round down to the ground. This is fixed by means of rods and pins, and protects the outer layer of barley. It is thus not only preserved from birds, but also from the effects of the weather, and the sample has none of those discoloured grains which deteriorate the value, but is equally clear and bright with the interior of the stack, if the barley has not been hurt in the field.

The practice of dibbling corn by hand is adopted, as far as the number of hands permit; but on a large farm it is

too slow an operation; the drill is therefore generally used, which will in one day sow ten acres of land. Machines for dibbling have been invented, and no less than four patents have been obtained lately for such inventions [SOWING MACHINES], but they have not yet been sufficiently tested by experience to be generally adopted.

Suffolk has but one breed of cattle which is peculiar to it. It is a polled breed, of which the cows are in great repute, and justly so. It is supposed that this breed has some relation to the Galloway and Aberdeen polled breeds; but this is mere conjecture. The cows are usually of a light red, sometimes spotted with white, of moderate size, and excellent milkers. The oxen have not been much attended to, as most of the bull-calves are fatted for the butchers or sent towards Essex and London for that purpose. Their aptitude to fatten has seldom been noticed; but the Suffolk cows, when barren, fatten well. A Suffolk cow has been known to give 30 quarts of milk per day, and of a good quality, for a considerable time after calving; but this is, no doubt, an extraordinary instance. Twenty quarts per day for three months is by no means uncommon, and sixteen may be considered as an average. This will give seven pints of butter, twenty ounces to the pint, per week—no bad produce.

The Suffolk farm-horses are noted for their docility, steadiness, and unwearied perseverance against a dead pull. In former days it was not unusual in fairs and markets to hook the traces of a horse to a ring in a post fixed into the ground. If the horse pulled till he went down on his knees, he was staunch; but if he ever refused his utmost exertions, he was despised. No better mode could be invented to spoil a good horse. The truly-bred Suffolk horses are active in their walk, which is their best pace. It is not easy for a man to keep pace with a Suffolk horse walking along the road. They step out well, and some of them can go at the rate of three miles an hour drawing a plough, and to this is owing the quantity of land usually ploughed in one day in the lighter lands of Suffolk and Norfolk. The usual mode is, as in Scotland, in two yokings, resting two or three hours between, in summer. The defect of the Suffolk horses, if it be any for a farm-horse, is to have rather coarse heads and very wide hips. Some of them are exceptions, and show fine proportions; and many a Suffolk mare has been put to a thorough-bred horse, and produced very fine foals for the carriage or the chase. But those who would try this cross should be very careful to select mares with fine heads, good shoulders, and not a falling croup. In spite of all precautions, the old points will come out, and occasionally spoil a very promising foal, even at the third or fourth generation.

Suffolk pigs are perhaps, on the whole, the most profitable breed in England. They are well-shaped, short-legged, mostly white, with short upright ears, and the porkers of this breed are excellent. It may be distinguished from the Essex breed by being better covered with hair, and from the Norfolk by having smaller ears set more nearly together. It is difficult to trace the crosses of so prolific an animal as a pig; but while the Essex have evidently much Neapolitan blood, the Suffolk seem to have more Chinese. Both crosses being excellent, it is useless to dispute the pre-eminence. The Suffolk pig is not so delicate in constitution as the Essex, and is therefore decidedly the best poor man's pig.

Suffolk has no indigenous breed of sheep; the Southdown and a cross of this breed with the Leicester and Cotswold are very common. The cross between the Southdown and Norfolk is increasing in reputation. The horns of the Norfolk sheep and his rambling propensities have been changed, and a quiet polled breed is the result. They are well shaped; and the mutton, if old enough, is excellent. They are getting more and more into favour.

The principal fairs in Suffolk are as follows:—Aldborough, Mar. 1, May 3; Beccles, Mond. in Whits. week; Bildestone, Ash Wed., Ascension-day; Botesdale, Holy Thursd., three weeks after Michaelmas-day; Boxford, Easter Mond., Dec. 21; Brandon, Feb. 14, June 11, Nov. 11; Bungay, May 14, Sept. 25; Bures, Holy Thurs.; Bury St. Edmunds, Tues. in Easter week and two following days, Oct. 2, Dec. 1; Clare, Tuesd. in Easter week, July 26; Debenham, June 24, Aug. 8; Eye, May 30; Framlingham, Whit Mond., Oct. 10; Hadleigh, Tuesd. in Whits. week, Oct. 10; Halesworth, Oct. 29; Haverhill, May 12, Aug. 26; Ipswich, May 4, Aug. 26, Sept. 25; Ixworth, May 13; Lavenham, Oct. 10, for four days; Shrove Tuesd.; Long-Melford, Tuesd. in Whits. week; Lowestoffe, May 12, Oct. 10; Mendlesham, Oct. 2; Mildenhall, Oct. 11; Nayland, Wed. after Oct. 2; Needham-Market, Oct. 28 and two following days; Orford, Mids.-day, Shrove Tuesd.; Saxmundham, Tuesd. in Whits. week, 1st Thurs. in Oct.; Southwold, Trin. Mond.; Stowmarket, July 10, Aug. 12, Oct. 1; Sudbury, Mar. 12, July 10, Sept. 4; Woodbridge, April 6.

Divisions, Towns, &c.—The county is divided into twenty-one hundreds, as follows, besides the liberty of the borough of Ipswich:—

Hundred.	Situation.	Area. Acres.	Population 1831.
Babergh	SW.	69,630	28,355
Blackbourn	N.	67,370	14,267
Blything	E.	83,850	24,177
Bosmere & Claydon	Central	50,640	12,956
Carlford	do.	22,550	6,348
Colneis	SE.	17,460	4,369
Cosford	Central	30,640	10,489
Hartismere	N.	55,240	17,871
Hoxne	N.	53,070	16,399
Ipswich (liberty)	SE.	7,020	20,201
Lackford	NW.	79,800	13,109
Loes	Central	33,290	13,544
Mutford and Lothingland	NE.	32,960	15,255
Plomesgate	E.	41,390	11,285
Risbridge	W.	59,160	16,215
Samford	S.	44,620	11,242
Stow	Central	22,010	8,308
Thedwestry	do.	39,820	10,103
Thingoe	do.	34,890	17,458
Thredling	do.	7,630	3,328
Wangford	N.	35,510	13,605
Wilford	SE.	30,180	7,433
Total	. .	918,760	296,317

The boroughs of Bury St. Edmunds and Sudbury are included respectively in Thingoe and Babergh hundreds.

Suffolk contains the two county and borough towns of Ipswich and Bury St. Edmunds, the parliamentary boroughs of Sudbury and Eye, the ex-parliamentary boroughs of Aldborough or Aldeburgh, Dunwich, and Orford: and the market-towns of Beccles, Bungay, Clare, Debenham, Framlingham, Hadleigh, Halesworth, Lavenham, Lowestoffe, Mildenhall, Newmarket, Saxmundham, Southwold, Stowmarket, and Woodbridge; with the ex-market towns of Bildesdon, Blythburgh, Botesdale, Brandon, Haverhill, Ixworth, Mendlesham, Needham-Market, Neyland, and Woolpit. Some of these are noticed elsewhere. [ALDBOROUGH; BECCLES; BUNGAY; BURY ST. EDMUNDS; IPSWICH; NEWMARKET.] Of the rest we subjoin an account.

Sudbury, in the Saxon chronicle Suth-beri, is in the hundred of Babergh, on the road from London to Bury, between 15 and 16 miles south of the latter town. It was anciently a place of consequence, and appears to have obtained its name to distinguish it from Bury St. Edmunds. It was one of the seats of the woollen manufacture established in England by the Flemings, in the reign of Edward III. Simon of Sudbury, archbishop of Canterbury, who was beheaded by Wat Tyler's mob, A.D. 1381, founded here a college of priests, whose yearly revenues at the dissolution were 122*l.* 18*s.* 3*d.* There were also a house of Dominican or Black Friars, a Benedictine cell to Westminster Abbey, and an hospital. The head and body of archbishop Simon of Sudbury were buried in the church of St. Gregory in the town; and the head, dried by art, was shown as late as the middle of the last century. The borough comprehends three parishes, All Saints, St. Gregory, and St. Peter; these have an area of 1250 acres; the population in 1831, was 4677. By the Boundary Act, the township of Ballingdon-cum-Brunden (in Hinckford hundred, in Essex, area 730 acres, population in 1831, 823), and some small extra-parochial districts, were added to the borough for parliamentary purposes, and the limits thus extended have been adopted for municipal purposes also. The town consists of several streets, irregularly laid out; it is a neat, clean, well-built place; the streets are paved, with flagged footpaths, and lighted. Many new houses have been built, and the town has been altogether much improved of late years. Ballingdon has one street, forming a suburb of Sudbury, with which it is united by a bridge over the Stour. The three churches are mostly of perpendicular character: they have all been fine churches, but some of the tracery and other parts have

been much mutilated. The Independents have a meeting-house. The town-hall is a modern building, and there is a neat theatre. The principal manufacture is of silk. By means of the Stour, which is navigable nearly up to the town for barges, trade is carried on in coals, which are imported, and in agricultural produce, which is exported. The navigation however is very bad. The market is on Saturday, and there is beside a corn-market on Thursday; there are two yearly fairs.

According to the census of 1831, 269 men in the borough and 5 men in Ballingdon, together 274 men, were employed in manufactures, besides women and children. The living of All Saints is a vicarage, of the clear yearly value of 119*l.*, with a glebe-house; the perpetual curacies of St. Gregory and St. Peter are united; their joint yearly value is 160*l.*, with a glebe-house. They are in the rural deanery and archdeaconry of Sudbury and diocese of Ely. There were in the borough, in 1833, eight day-schools, of all kinds, with 365 children, viz. 232 boys, 117 girls, and 16 children of sex not stated; and two Sunday-schools, with 233 children, viz. 120 boys and 113 girls. Two of the day-schools were national schools, and were attended on Sunday by 382 children, viz. 180 boys and 202 girls. Sudbury was incorporated by charter of Queen Mary, A.D. 1554. By the Municipal Reform Act it has 4 aldermen and 12 councillors, with a commission of the peace. It returns two members to parliament; the number of voters on the register in 1835-6 was 578; in 1839-40, 594.

Archbishop Simon of Sudbury, Gainsborough the painter, and Dr. Enfield, a dissenting minister of considerable note, were born at Sudbury.

Eye is in the hundred of Hartismere, about 20 miles north of Ipswich. It is on a feeder of the Waveney, now a mere rivulet, but probably navigable at a former though very remote period. Small rudders and other tackle belonging to boats are said by Leland (*Collectanea*, vol. iv., edit. 1770, p. 26) to have been dug up from time to time by the monks of Eye, in clearing out the ditches. The town was incorporated by King John, and sent two members to parliament from the time of Elizabeth to the passing of the Reform Act, when it was reduced to one member. There are some slight remains of the castle, belonging to the Malet family, one of whom founded at Eye a small Benedictine priory, whose yearly revenues at the dissolution were 184*l.* 9*s.* 7½*d.* gross, or 161*l.* 2*s.* 3¼*d.* clear. There are some remains of the monastic buildings, now used as stables, on the east side of the town. The streets of Eye are irregularly laid out and narrow, and the houses are mean. The church is handsome and spacious, with a fine tower of perpendicular character: there are Baptist and Wesleyan meeting-houses. The area of the borough and parish is 2370 acres; the population, in 1831, was 2313. There is little trade, and no manufacture, except a trifling one of lace. The general market is on Saturday, the corn-market on Tuesday, and there are two yearly fairs. The municipal boundaries are coincident with those of the parish of Eye. Before the passing of the Municipal Reform Act, the municipal authorities had no exclusive jurisdiction; no sessions were held, and the court of record had long gone into disuse; under the Municipal Reform Act the borough has 4 aldermen and 12 councillors, but is not to have a commission of the peace except on petition and grant. By the Boundary Act the adjacent the parishes of Hoxne, Denham, Redlingfield, Occold, Thorndon Braisworth, Yaxley, Thrandiston, Broome, and Oakley were, for parliamentary purposes, added to the borough, which thus includes an extensive rural district, about 20,000 acres, with a population, in 1831, of 7015. The number of voters on the register, in 1835-6, was 278; in 1839-40, 332. The living of Eye is a vicarage, of the clear yearly value of 331*l.*, with a glebe-house, in the rural deanery of Hartismere, archdeaconry of Suffolk, and diocese of Norfolk. There were in the borough and parish, in 1833, two dame-schools, with about 60 children; four other day-schools, with 99 children, 47 boys and 52 girls; and three Sunday-schools, with about 280 children of both sexes. One of the day-schools is partly supported by an endowment and a grant from the corporation.

Dunwich is on the coast, in the hundred of Blything, 28 miles from Ipswich, through Woodbridge and Rendlesham. While East Anglia subsisted as a separate kingdom, Dunwich was a place of importance, and the seat of the first East-Anglian bishopric, which may be considered as the predecessor of that which is now fixed at Norwich. It is called in the Saxon Chronicle Domuce or Domuc, and is variously written in other antient authorities Domoc, Dommoc, and Dommoc-ceaster. Various notices in antient authors show it to have been still a place of importance in the time of the Plantagenets, though it appears to have declined under the rising importance of Southwold and Yarmouth. It was the seat of a considerable herring fishery. It was threatened by the insurgents, who in the rebellion of the younger Henry against his father Henry II. overran the county. In the civil war of John, the townsmen adhered to the king, who had befriended the town, and granted it a charter of incorporation. They lost several vessels, and many men, which they had contributed to the king's naval service in the French wars of Edward I. and III. In the war of the roses, they embraced the Yorkist party; and this, by inducing Henry VII. to incorporate the rival town of Southwold, contributed to the decay of the place. But this decay was mainly owing to the encroachment of the sea, which not only ruined the port, but washed away the greater part of the town. Of seven parish churches which it once contained, one only (All Saints) remains, and that is a mere ruin, in the place of which a new church (St. James's) was built a few years since by subscription. Besides All Saints church there are the remains of a Grey Friars' house, and of the chapel of St. James's hospital: they all contain some portions of good architecture, partly Norman. Dunwich is at present a mere village. The market has been discontinued. There is a yearly fair, and some sprats and herrings are caught and cured. The area of the borough and parish (for these are co-extensive) is 3240 acres. The population in 1831 was 232. The corporation has been maintained chiefly for parliamentary purposes, and, as the borough was disfranchised by the Reform Act, will probably go to decay. It has a revenue of about 150*l.* a-year, and is untouched by the Municipal Reform Act. Sessions are held once a year by the borough magistrates, and an Admiralty Court occasionally. The living of Dunwich is a perpetual curacy, of the clear yearly value of 40*l.*, in the rural deanery of Dunwich, in the archdeaconry of Suffolk, and diocese of Norwich. The only school in the parish in 1833 was a Sunday-school, containing from 30 to 40 children, about half of each sex.

Orford is in Plomesgate hundred, 21 miles from Ipswich through Woodbridge. There was a royal castle here in the time of Henry III., who granted a charter to the town, which was previously a borough by prescription. It is now, like Dunwich, a mere village; the market has been given up; and as the borough was disfranchised by the Reform Act, the corporation, which was kept up for parliamentary purposes, will probably become obsolete. It is untouched by the Municipal Reform Act. It has an income of less than 100*l.*, and its jurisdiction is growing into disuse. The area of the borough and chapelry of Orford, including the adjacent hamlet of Gedgrave, is 2740 acres: the population in 1831 was 1302. The village consists of ill-built houses, irregularly laid out, on the north-east bank of the river Alde or Ore, which is navigable. The chapel, when entire, was a large building: the nave alone is now used, and is separated by a wall at the east end of it from the chancel, which is more antient, and has been allowed to fall to ruin. There are some curious portions in the nave. The ruins of the chancel are of Norman architecture: the piers are much varied, and some of them of singular shape. There is a curious font. Only the keep of the castle remains: it is a polygon of eighteen sides, with walls 90 feet high, and has three square towers in its circuit, which overtop the rest of the building. The architecture is Norman. Not far from the town, on the sea-shore near Orford Ness, are two light-houses. The chapelry of Orford is in the parish of Sudbourne, and the benefice is united with the rectory of that parish; they are in the rural deanery of Orford, archdeaconry of Suffolk, and diocese of Norwich: their joint clear yearly value is 577*l.*, with a glebe-house. There were in the borough in 1833 ten day-schools of all sorts (chiefly dame-schools) with 252 children; and two Sunday-schools, with 316 children, viz. 146 boys and 170 girls. There is a lending library for the use of the borough and the parish of Sudbourne. Orford gives the title of earl to the Walpole family.

Clare is in Risbridge hundred, 18 miles south-south-west from Bury. The area of the parish is 3410 acres. The population of the parish in 1831 was 1619, from one-third to one-half agricultural. The town is on the north bank of

the river Stour. The streets are wide, but not paved or lighted, and the houses generally are of mean appearance. The church, which is in the centre of the town, is a fine large building; it has a handsome octagonal font of perpendicular character, and a brass eagle on a pedestal, with the wings expanded, forming the reading-desk. There are places of worship for Baptists and Independents. On the south side of the town are the vestiges of an old castle; the site may be traced, and it appears to have comprehended an area of about twenty acres. The mound on which the keep stood, and some fragments of the walls of the keep, yet remain. Near the ruins of the castle are the remains of a priory of regular canons of St. Augustin; part of the buildings are occupied as a dwelling, and the chapel is converted into a barn. The lordship of Clare gave name to an illustrious family, and the titles of earl of Clare and duke of Clarence were derived from it. There is a weekly market, and there are two small yearly fairs. The living is a vicarage in the rural deanery of Clare, in the archdeaconry of Sudbury, and diocese of Ely, of the clear yearly value of 195*l.*, with a glebe-house. There were in the parish, in 1833, twelve day-schools of all kinds, with 265 children, viz. 116 boys and 149 girls: and three Sunday-schools, with 310 children, viz. 143 boys and 167 girls.

Debenham is in the hundred of Thredling, 13 miles north of Ipswich, on the river Deben, here a mere brook. The area of the parish is 1920 acres. The population in 1831 was 1629, about half agricultural. From its situation on a declivity, the town is clean, but the houses are generally poor. The church is a handsome edifice, and the market-house is a tolerably good building. There is a place of worship for Independents. The market, which is on Friday, is small. There is one yearly fair. The living is a vicarage, in the rural deanery of Cleydon, the archdeaconry of Suffolk, and the diocese of Norwich, of the clear yearly value of 154*l.*, with a glebe-house. There were in the parish, in 1833, three day-schools, with 133 children, viz. 84 boys and 40 girls; and two Sunday-schools, with 279 children, viz. 80 boys, 67 girls, and 132 children of sex not stated. One of the day-schools has an endowment.

Framlingham is in the hundred of Loes, 18 miles north-north-east of Ipswich. It was probably a place of consequence in the Anglo-Saxon period, and St. Edmund, king of the East Angles, is said to have been besieged here by the Danes, A.D. 870. In the middle ages it was important from its strong castle, granted by Henry I. to Hugh Bigod, and at different times held by the Bigods, the Mowbrays, the Howards, and other illustrious families. Sir Robert Hitcham, having purchased the castle and manor of the Howard family, bequeathed them for pious uses to the master and fellows of Pembroke Hall, Cambridge, by which society they are still possessed. The parish of Framlingham has an area of 4470 acres; the population in 1831 was 2445, about two-fifths agricultural. The town stands near the head of the river Ore, which just to the north of the town expands into a spacious pond or mere. The streets are irregularly laid out, but there is a spacious market-place of triangular form, and the houses are many of them well built and respectable. The streets are lighted with oil. The church is in the middle of the town; it is large and handsome, built of black flint, with a tower 96 feet high, in which is a peal of eight bells. The roof of the nave is of curiously carved oak; and in the church are several monuments of the Howards (among them those of Thomas, second duke of Norfolk, and his son the accomplished earl of Surrey, beheaded by Henry VIII.), and the monuments of the duke of Richmond, natural son of Henry VIII., and of Sir Robert Hitcham. On the north side of the town, adjacent to the mere, are the ruins of the castle. The outer wall is yet standing: its form is irregular, approaching to a circle, and it is strengthened at intervals by square towers, thirteen in number. The wall is 44 feet high and 8 feet thick; the towers rise to the height of 58 feet. The principal gateway is on the south side, opposite the town, and is adorned with the arms of the principal families which have possessed the castle, carved in stone. There are some remains of the outworks. The area comprehended by the walls of the castle is above an acre and a quarter; but the demolition of the interior is so complete, that very little idea can be formed of its arrangement. In the vacant area are, or were lately, an almshouse and a workhouse, built of the materials of the castle. The castle was defended, except where it was protected by the mere, by a double ditch, which still remains. There are in the town an almshouse and a free school founded by Sir Robert Hitcham, a second almshouse founded by Thomas Mills, and places of worship for Unitarians, Independents, and Wesleyans. Some malting is carried on in the town. There is a market on Saturday for corn, and occasionally for cattle; and there are two yearly fairs. The living is a rectory, united with the chapelry of Saxtead, which is in the parish, of the clear yearly value of 1201*l.*, in the gift of Pembroke Hall, Cambridge. It is in the rural deanery of Loose (or Loes), in the archdeaconry of Suffolk, and diocese of Norwich. There were, in 1833, twelve day-schools of all kinds, with 294 scholars, namely, 98 boys, 93 girls, and 103 children of sex not stated; and four Sunday-schools, with 378 scholars, namely, 61 boys, 33 girls, and 284 children of sex not stated. Two of the day-schools have endowments, one bequeathed by Sir Robert Hitcham, the other by Thomas Mills.

Hadleigh is in Cosford hundred, 9 miles west of Ipswich. It is said to have been the burial-place of Guthrum the Dane, to whom Alfred ceded East Anglia; and has some interest as the place of martyrdom of Dr. Rowland Taylor, burned in the persecution under Queen Mary, on what is commonly but improperly called Aldham Common, near the town. (Fox's *Acts and Monuments of the Church*, edit. of 1576, pp. 1445-1456.) A stone with this inscription—

'Anno 1555,
Dr. Taylor, for defending what was god,
In this place shed his blod'

marks the spot. The parish of Hadleigh has an area of 3410 acres: the population, in 1831, was 3425, less than one-third agricultural. The town consists of one principal street, running from south-south-east to north-north-west, and other smaller ones branching from it; but none of the streets are paved or lighted. The church is large and handsome, with a tower and spire and two south porches. The aisles and clerestory extend along the chancel as well as the nave. The architecture is chiefly of perpendicular date, but some portions are earlier. The monument shown in this church as the monument of the Anglo-Danish king Guthrum is of later date than the ninth century, in which he died. The rectory-house, adjacent to the churchyard, is antient, and in front of it is a brick gateway with two hexangular towers of the same date (about A.D. 1490) as the house. There are meeting-houses for Independents, Baptists, and Wesleyans; and a range of twelve almshouses with a chapel, built by William Pykeham, rector of this parish, who built the rectory-house and gateway. Some weaving is carried on in the town. There is a good corn and general market on Monday, and there are two yearly fairs: the corn-exchange or market-house is a good modern building. Hadleigh was formerly a corporate town, but the charter was surrendered in the time of James II., and never restored. The living is a rectory, in the peculiar jurisdiction of the archbishop of Canterbury, of the clear yearly value of 929*l*, with a glebe-house. There were in the parish, in 1833, six day-schools, with 132 scholars, viz. 70 boys, 32 girls, and 30 children of sex not stated; four boarding-schools, for which no return was made; two day and Sunday national schools, with 213 children (90 boys and 123 girls) in the week, and 262 children (121 boys and 141 girls) on Sundays; and one Sunday-school, with 210 children, viz. 90 boys and 120 girls. One of the day-schools had three small endowments.

Halesworth is in Blything hundred, 31 miles north-north-east of Ipswich through Woodbridge and Saxmundham. The area of the parish is 1070 acres; the population, in 1831, was 2473, one-fifth agricultural. The town is irregularly laid out: a small stream runs through it, and joins the river Blyth half a mile south-east of the town. The streets are wide, but not paved; and some of the houses are well built. The town is lighted with oil. The church is a handsome Gothic building; and there are places of worship for Baptists and Independents. On the south side of the town is a small theatre. There are some large malthouses, and a considerable trade in malting is carried on. The river Blyth and its branch are made navigable up to the town, and afford facility for the export of agricultural produce, and the import of coal, lime, and general merchandise. There is a corn and general market on Thursday, and there is also a yearly fair. The living is a rectory united with the vicarage of Chediston, in the rural deanery of Dunwich, the archdeaconry of Suffolk, and the diocese of Norfolk, of the joint clear yearly value of 450*l.*, with a glebe-house. There were in the parish, in 1833, an infant-school, with 40 children, chiefly

girls, supported by voluntary contributions; eleven day-schools, with from 267 to 287 children, viz. 117 boys, 120 girls, and from 30 to 50 children of sex not stated; one day and Sunday national school, with 200 children, an equal number of each sex; and one Sunday-school, with 110 children, viz. 50 boys and 60 girls. There were also an evening-school and a lending library.

Lavenham (colloquially shortened into Lanham) is in the hundred of Babergh, 10 miles south-south-east of Bury. The area of the parish is 2800 acres, and it had a population in 1831 of 2107, about one-third agricultural. It is in a healthy situation on the declivity of a hill, at the foot of which flows the little river Bret. It is irregularly laid out, the houses are mean, and the streets are neither paved nor lighted. The market-place is spacious, and there is a stone cross in the centre. There is a bridewell in the town. Lavenham was formerly the seat of a considerable manufacture of blue woollen cloth, and for the regulation of this trade three guilds or companies were established. The wool-hall of the town was much frequented. This manufacture has long passed away, as well as the manufacture of shalloons and serges which succeeded it, and of hempen cloth, a branch of industry of still later date. A little wool-combing and spinning and a little silk-weaving are still carried on. There is a market, almost disused, on Tuesday, and there are two yearly fairs. Formerly the town was governed by six capital burgesses chosen for life; but the authority of these officers, if not the office itself, has come into disuse. The church is large and handsome; it is 156 feet long, 68 feet wide, and has a steeple 141 feet high. The character of the architecture is perpendicular, the clerestory is lofty, and the tower fine, with bold buttresses. The battlements and some other portions are much enriched. The roof is curiously carved; the windows are numerous, and some of them are still embellished with painted glass; and there are one or two remarkable monuments. There are meeting houses for Independents and Wesleyans, and there are several almshouses belonging to the town. The living is a rectory, in the rural deanery and archdeaconry of Sudbury, and the diocese of Ely, of the clear yearly value of 658*l*., with a glebe-house. There were in the parish, in 1833, six day schools, with 125 children, viz. 72 boys and 53 girls; two day and Sunday national schools, with 150 children (75 boys and 75 girls) in the week, and 140 children (70 boys and 70 girls) on Sunday; and two Sunday-schools, with 148 children, namely, 57 boys and 91 girls. One of the day schools is an endowed grammar-school; and two other day schools are partly supported by endowment.

Lowestoffe or Lowestoft, colloquially Laystoff, as it was formerly written by some persons, is in the hundred of Lothingland, 45 miles north east of Ipswich, on the sea. The parish has an area of 1950 acres; the population in 1831 was 4238, scarcely any part of it agricultural. The town stands on the top of a cliff facing the sea, from which it is separated by a beach, in some parts nearly half a mile wide. It consists of one principal well-paved street, nearly a mile long, running north and south, lined with good modern brick houses, and of some smaller streets opening into this on the west side. The houses on the east side of the High-street have gardens at the back sloping down the face of the cliff towards the sea. Buildings have accumulated at the bottom of the cliff on the beach, where the curing-houses for herrings and a rope-walk are situated. The parish church is a large and handsome church of perpendicular architecture, situated nearly half a mile west of the town. The length of the whole building is 182 feet, the breadth 57 feet, the height 43 feet; it has a tower and spire 120 feet high, 50 feet of which belong to the spire. The windows are large and fine, and the east end of the church has some chequer-work of flint and stone. There are in the church an antient font and a number of monuments, including those of Thomas Scroope, bishop of Dromore, who died here, A.D. 1491, of admirals Sir John Ashby and James Mighells, of Potter, the translator of Æschylus and Sophocles, and of several others. There is a chapel-of-ease in the town; and there are places of worship for Baptists, Independents, and Methodists. There are a town-hall or chamber over the market or 'corn-cross,' a theatre, and near the south end of the town a bathing-house. On the cliff is the upper lighthouse, and on the beach are a battery at the south end of the town, and the lower lighthouse. Off the shore are the North and South roads, sheltered to sea-ward by the Corton and Newcome sands. The upper lighthouse is of brick and stone, with a cylindrical revolving lantern furnished with powerful reflectors; the lower lighthouse is of timber. South of the town is the cut communicating between Lake Lothing and the sea, forming part of the line of the Norwich and Lowestoffe navigation. The tide-lock will admit vessels 84 feet long and 21 feet in beam. The principal branch of industry at Lowestoffe is the fishery, which occupies about 200 men. Great quantities of mackerel and soles are caught, and sent to the London and Norwich markets; and a great quantity of herrings are taken and cured. There are rope and twine manufactories. The market is on Wednesday, and there are two yearly fairs. Lowestoffe is also frequented as a bathing-place. The living is a vicarage, in the rural deanery of Lothingland, in the archdeaconry of Suffolk, and the diocese of Norwich, of the clear yearly value of 323*l*., with a glebe-house. There were in the parish, in 1833, an infant-school, with 100 children of both sexes; fourteen day-schools of all kinds (two of them endowed, and one partly supported by subscription), with 125 children, namely, 186 boys, 123 girls, and 116 young children of sex not stated; and two Sunday-schools, with 205 children, namely, 120 boys and 85 girls. There is a lending library in the parish.

Mildenhall is in the hundred of Lackford, 12 or 13 miles north-west of Bury. The parish is extensive, comprehending a considerable district of fenland, and including, beside the town, several detached hamlets, locally termed 'rows,' as Holywell Row, north of the town; Beck Row, north-west; and West Row, west-north-west. The area of the parish is 13,710 acres. The population in 1831 was 3267, about half agricultural. The town stands just on the border of the fen country, which stretches northward into Norfolk, and westward into Cambridgeshire, and is a little to the left of the road from London to Norwich by Newmarket, Barton-Mills, and Thetford. It is irregularly laid out, and the streets are neither paved nor lighted, but the houses are for the most part well-built. The church is large and handsome, with a tower 120 feet high. It has a handsomely carved wooden roof and several monuments. There are meeting-houses for Baptists and for Calvinistic and Wesleyan Methodists. The market, which is on Friday, is well supplied with provisions, especially fish and wild-fowl; and there is a considerable yearly fair. The river Larke, which passes close to the south side of the town, is navigable, and facilitates the export of corn and agricultural produce, in which considerable business is done. The living is a vicarage in the rural deanery of Fordham, in the archdeaconry of Sudbury, in the diocese of Ely, of the clear yearly value of 369*l*. There were in the parish, in 1833, fifteen day-schools, with 330 children, namely, 159 boys and 171 girls; and four Sunday-schools, with 395 children, namely, 196 and 199 girls. One of the day-schools was a national school, with 60 girls, and was partly supported by endowment. The handsome seat of Sir H. E. Bunbury is in the town.

Saxmundham is in the hundred of Plomesgate, 20 miles north-east of Ipswich, on the road to Yarmouth. The area of the parish is 1460 acres; the population in 1831 was 1048, about one-fourth agricultural. The town consists chiefly of one long, narrow, unpaved street, running north and south along the high road, lined with neat, respectable-looking houses. It is in a valley, through which, at the back of the houses, on the east side of the street, runs a small brook, a feeder of the Alde, which it joins about four or five miles south of the town. The church is a neat building just out of the town; and there is a place of worship for Independents. Some business is done in malting and in shipping corn for London from the wharfs on the river Alde. The market is on Thursday, and there are two yearly fairs. The living is a rectory in the rural deanery of Orford, in the archdeaconry of Suffolk, in the diocese of Norwich, of the clear yearly value of 275*l*., with a glebe-house. There were in the parish, in 1833, six day-schools of all sorts, with 132 children, namely, 51 boys and 81 girls; and three Sunday-schools, with 147 children, namely, 80 boys and 67 girls.

Southwold is in the hundred of Blything, on the coast, 36 miles north-east of Ipswich by Woodbridge and Saxmundham. It was in the middle ages a place of some importance, and the townsmen were engaged in frequent disputes with those of Dunwich, occasioned probably by the commercial rivalry of the two places. In the reign of Henry VII. Southwold was incorporated by act of parliament, and the corporate rights of the townsmen were confirmed by bsequent charters of Henry VII. and his successors. In

1659 the town was nearly consumed by a fire, which destroyed the town-hall, the market-house, the prison; besides granaries, shops, warehouses, above two hundred and thirty houses; beside fishhouses, malthouses, brewhouses, and other outbuildings; and a great quantity of corn, merchandise, fishing-nets, and other tackle. The damage was estimated at more than 40,000*l*., and above three hundred families were ruined. It is probable that the town has never reached the prosperity which it enjoyed before this calamity. The area of the borough and parish (which are coincident) is 680 acres: the population, in 1831, was 1875, scarcely any part agricultural. The town is on a hill, forming a cliff toward the sea, and sinking on the other side into the marshes through which the river Blyth, and an arm of it called 'the Buss Creek,' flow. By these waters the hill on which the town stands is almost insulated. The only entrance to the town is on the north-west side, by a bridge over the Buss Creek: and the main street is on the road from this bridge to the face of the cliff: it has flagged footpaths, and is lined near the sea with respectable houses; but in other parts the houses are of inferior character. The top and sides of the hill round the town are unenclosed land, chiefly or wholly common; and there are two windmills and a lime-kiln. The church is near the entrance of the town, on the north-west side, and is a large and handsome building of perpendicular architecture, mostly of flint and stone: it is 143½ feet long, and above 56 feet wide. The western tower is about 100 feet high; and there are two low hexagonal towers at each angle of the eastern end of the chancel. There is a highly ornamented porch, of somewhat later date than the church. The interior of the church has been richly ornamented, but has been much defaced: the painted ceiling of the chancel still remains, and the magistrates' pews are adorned with gilding and painting. There are meeting-houses for Baptists, Methodists, and Independents. The town-hall is a modern building, and there is a small gaol. The principal branch of industry is the fishery, which, in 1831, employed one hundred men: there are some salt-works. Red herrings, red sprats, salt, corn, and malt are exported: and coal is imported. The town is frequented in the bathing season by visitors from the adjacent counties. The quay is on the Blyth, above half a mile south-west of the town.

The Municipal Reform Act assigns to the borough four aldermen and twelve councillors: it is not to have a commission of the peace except on petition and grant. The corporation revenue, derived chiefly from common, marsh, and other lands, is about 800*l*. or 900*l*. a year. The living is a perpetual curacy, in the rural deanery of Dunwich, the archdeaconry of Suffolk, and the diocese of Norwich, of the clear yearly value of 60*l*., with a glebe-house. There were in the parish, in 1833, nine day-schools of all sorts, with from 193 to 213 children, namely, 83 boys, 80 girls, and from 30 to 50 children of sex not stated; and three Sunday-schools, with 316 children, namely, 177 boys and 139 girls. One of the day-schools had an evening class of 10 adults.

Stow-Market is in the hundred of Stow, 12 miles north-west of Ipswich, on the road to Bury, from which it is distant 14 miles east-south-east. The parish has an area of 1240 acres: the population, in 1831, was 2672, about one-sixth agricultural. The town consists of one main street along the Bury and Ipswich road, and of some smaller ones; the streets are for the most part paved, and lined with tolerably good houses; indeed several of the houses are very good, and the town is lighted with gas. The church is spacious and handsome, built of flint and stone: the architecture is partly decorated, partly perpendicular. The tower, which contains a peal of eight bells, is surmounted with a light and elegant wooden spire, the whole being 120 feet high. There are places of worship for Baptists and Independents. There is a small manufacture of rope, twine, and sacking; an iron-foundry; and a great number of malt-houses. Near the town are hop-plantations, brick-yards, and a water-mill. The Gipping has been made navigable up to the town, and a considerable quantity of corn and malt are sent in river-craft down to Ipswich to be shipped there: timber and deals, coals and slate, are brought up from Ipswich for the supply of the neighbourhood. The bank of the river forms an agreeable walk. There is a well-supplied corn, cattle, and general market on Thursday; and there are three yearly fairs. The living is a vicarage united with the adjacent vicarage of Stow-Upland, in the rural deanery of Stow, the archdeaconry of Suffolk, and the diocese of Norwich: their joint clear yearly value is 281*l*., with a glebe-house. There were in the parish, in 1833, seventeen day-schools, with 199 boys and 188 girls, together 387 children; one day and Sunday national school, with 64 boys and 42 girls, together 106 children; and two Sunday-schools, with 141 boys and 139 girls, together 280 children.

Woodbridge is in the hundred of Loes, on the river Deben, 7 miles east-north-east of Ipswich on the road to Yarmouth. The area of the parish is 1650 acres; the population, in 1831, was 4769, scarcely any part of it agricultural. The town stands on the north-west bank of the river, which, at high-water, is a quarter of a mile wide: it consists of two principal streets (one of them near a mile long), which contain many good houses and are well paved; and of several smaller streets and lanes. The market-place is spacious, and surrounded with well-built houses: in the centre of it is an antient shire or sessions hall, in which quarter-sessions for the division are held: the lower part of the hall is the corn-market. The church is large and handsome, built chiefly of black flint: it has a large square tower, built of flint and stone, 180 feet high: toward the top the flint and stone are so intermingled as to form various devices. In the church are several monuments. There are places of worship for Quakers, Independents, Baptists, and Methodists. There are a custom-house, a small theatre and barracks, and near the town is a bridewell. Woodbridge is a place of considerable trade: it is a port, and the river Deben is navigable for small coasting vessels: the tide flows above the town. Corn, malt, and flour are exported; and coal, timber, and general merchandise imported. There are two good quays on the bank, and formerly small vessels were built in the Limekiln Docks. The market is on Wednesday for corn, cattle, and provisions; and there are two yearly fairs. The living is a perpetual curacy, in the rural deanery of Carlesford, in the archdeaconry of Suffolk, and diocese of Norwich, of the clear yearly value of 500*l*. There were in the parish, in 1833, six dame-schools, with 44 boys and 56 girls, together 100 children; seventeen other day-schools, with 360 boys and 311 girls, together 671 children; one day and Sunday national school, with 218 boys and 104 girls, together 322 children; and four Sunday-schools, with 157 boys and 256 girls, together 413 children. There are a range of almshouses in the town, for the support of which, and for other charitable purposes, Thomas Seckford, master of requests in the reign of Queen Elizabeth, left an estate in Clerkenwell, one of the suburbs of London, the increased value of which estate has rendered the charity very wealthy. Woodbridge had before the Reformation a small priory for canons of St. Augustin adjacent to the church. The yearly revenue at the dissolution was 50*l*. 3*s*. 5½*d*.

Bildeston, or Bilston, is in Cosford hundred, on a small stream which flows into the Bret, about 14 miles west-north-west from Ipswich. It had formerly a considerable manufacture of blue cloth and blankets; but this branch of trade has long been given up. Some yarn is spun. The market, which was on Wednesday, is disused; but there are two yearly fairs. The area of the parish is 1420 acres: the population, in 1831, was 836, about one-third agricultural. The church is a good building, on a hill west of the village; and there is a Baptist meeting-house.

Blythburgh is in Blything hundred, on the south bank of the Blyth, 30 miles north-east of Ipswich. The area of the parish is 3590 acres: the population in 1831 was 579, almost entirely agricultural. It is a place of great antiquity; and Anna, king of the East Angles, who fell in battle against Penda of Mercia, in the time of the Heptarchy, is said to have been buried here. It was in the middle ages an important fishing and trading town. Sessions for the division were held here, and there was a gaol, of which some portions remained to the middle of the last century. The church has been a very fine building, highly ornamented both within and without: the architecture is of perpendicular character; but the tracery and other parts have been much defaced. The length of it is 127 feet, the width above 54 feet. There are some remains of painted glass in the windows, and there are some monuments, one of which is pointed out, but erroneously, as that of Anna, the East Anglian king, and another as that of his son, who fell in the same battle. There are some remains of a priory for the canons of St. Augustin; this priory was a dependency of the abbey of St. Osyth in Essex; its yearly revenues at the dissolution were 48*l*. 8*s*. 10*d*. There are some remains of another religious house. The suppression of the religious

houses, and a great fire in 1676, are supposed to have led to the decay of the town.

Botesdale is in the hundred of Hartismere, 15 miles north-east from Bury, on the road to Norwich by Scole. With the village of Rickingall Inferior, which is in Blackburn hundred, it forms a street of more than a mile long, lined with indifferently built houses. The area of the two parishes is 2050 acres; their joint population in 1831, 1120, nearly half agricultural. The market, formerly held at Botesdale on Thursday, has been discontinued, but there is a yearly fair. The chapel at Botesdale (the parish is only a parochial chapelry) has some good portions of perpendicular architecture. It is dedicated to St. Botolph; and the name of the village is a corruption of St. Botolph's dale. Near the church is the grammar-school, which had, in 1833, above 30 scholars. Near Botesdale is Redgrave Hall, the handsome seat of Admiral Wilson; and in Redgrave church, which is about 2 miles from Botesdale, is a handsome monument to chief-justice Sir John Holt.

Brandon is in the hundred of Lackford, about 17 miles north-north-west of Bury, through Thetford. The area of the parish is 5570 acres; the population in 1831 was 2065, barely one-tenth agricultural. The village consists of three streets along the Mildenhall, Elvedon, and Thetford roads, which converge and form one main street leading by a neat stone bridge over the Little Ouse into Norfolk. The houses are for the most part well built. The church is a little out of the village on the south-west, and is a good structure. The market has been discontinued for many years; but there are three yearly fairs. There are extensive rabbit-warrens in the neighbourhood, of which one alone is said to have furnished to the London market 40,000 rabbits yearly. Continuous strata of the finest flint occur in the chalk near the town, and are dug and manufactured into gun flints, a branch of industry that in 1831 gave employment to 60 men. Considerable trade is carried on in corn, malt, coal, timber, and other goods, favoured by the navigation of the little Ouse or Brandon river, which passes on the north side of the village. The duke of Hamilton and Brandon takes his latter title from this village. There is an endowed free school.

Haverhill is in Risbridge hundred, about 16 miles south-east of Bury: both village and parish extend into the adjacent hundred of Hinckford, in the county of Essex. The area of the parish is 3320 acres; the population in 1831 was 2025, probably a fourth agricultural. The village consists of one principal street, wide, but lined with poor houses, running from south-east to north-west along the road from Colchester to Cambridge. The church is a large antient building, and there are two dissenting places of worship. There was antiently another church, and half a mile north-west of the town was a castle, of which there are no remains. The market has been for some years discontinued, but there are two yearly fairs. In the year 1831, 173 men were employed in the manufacture of drabbets and Tuscan plat.

Ixworth is in Blackbourn hundred, 7 miles north-east of Bury. The area of the parish is 2320 acres; the population in 1831 was 1061, more than half agricultural. There was antiently a priory for the regular canons of St. Augustin, founded about A.D. 1100; the yearly revenues of which at the dissolution were 280*l*. 9*s*. 5*d*. (or, according to some authorities, 204*l*. 9*s*. 5½*d*.) gross, or 168*l*. 19*s*. 7¾*d*. clear. The village consists of one main street along the road from Bury to Norwich by Scole, and of one or two smaller streets. There are some remains of the priory, near which is the parish church, as mall but antient building. Some Roman remains have been discovered near the village. The market was given up some years since.

Mendlesham is in Hartismere hundred, about 15 miles north-north-west of Ipswich. The parish has an area of 4420 acres: the population in 1831 was 1233, more than two-thirds agricultural. The village consists of mean houses, and the market has long been given up. The church is a handsome building, and there is a Methodist meeting-house. An antient silver crown of sixty ounces weight was found here near the close of the seventeenth century: it was supposed to have belonged to one of the East Anglian kings.

Needham-Market is in Bosmere and Claydon hundred, 8 miles north-west of Ipswich, on the road to Bury. The area of the parish of Barking, in which the place stands, is 3010 acres: the population in 1831 was 1884, of which 1466 persons belonged to the hamlet or chapelry of Needham-Market. The village consists of one principal street and of some smaller ones: the houses are neat, and some of them even handsome. The chapel is a mean building, with a wooden belfry; and there are one or two dissenting places of worship. The woollen manufacture, formerly carried on here, has been long extinct; and of late years the market has been given up: a little paper and glue are made. The Gipping, which passes the town, is navigable. There is an endowed grammar-school.

Neyland or Nayland is in the hundred of Babergh, 13 or 14 miles west-south-west of Ipswich. The area of the parish is 1470 acres: the population in 1831 was 1047, about one-third agricultural. The village is in a low situation, on the north bank of the river Stour, over which there is a brick bridge, and is occasionally subject to inundation. There are some good dwelling-houses in the place, and some large flour-mills: a considerable quantity of corn and flour is sent down the Stour to be conveyed to London. There is a yearly fair. The church is a handsome building, and there is a meeting-house for Independents. There is a national school. The market has been given up for some years, and the woollen manufacture, once flourishing, is quite extinct.

Woolpit is in the hundred of Thedwestry, 8 miles east by south of Bury, on the road to Stow-Market and Ipswich. The area of the parish is 2010 acres; the population in 1831 was 880, less than half agricultural. The church is built partly of flint and chalk; it is a handsome building, partly of decorated, partly of perpendicular character. There is a large south porch, much enriched, but the spire is mean. The market has long been given up; but there is a yearly cattle fair, one of the largest in the county, if not in England. A very white brick, of remarkably neat and beautiful appearance, is made near the village.

The following villages may just be noticed. Long Melford is in Babergh hundred, about 2 miles north of Sudbury. It consists of one street, nearly a mile in length, extending along the road from Sudbury to Bury. The church is large, and of perpendicular character, with an extensive building, [in chequer-work, of flint and stone at the east end. Melford has some old mansion-houses and an alms-house or hospital The population in 1831 was 2514, about one-third agricultural. Yoxford, in Blything hundred, is on the Yarmouth road, about 4 miles beyond Saxmundham. It is pleasantly situated and has a well-built street of modern houses. The population in 1831 was 1149. Hoxne (antiently Eglesdune or Hagilsdun) has some historical interest as the place where St. Edmund was taken and killed by the Danes. It is in the hundred of Hoxne, on the bank of the Waveney, not far from Eye. The population in 1831 was 1243. Fressingfield, in the same hundred, was the birthplace of Archbishop Sancroft, and the place to which he retired after his deprivation The population in 1831 was 1352. Stradbrook (population in 1831, 1527), in the same hundred, was the birthplace of Robert Grosseteste, bishop of Lincoln. East Bergholt and Stratford St. Mary are both in Samford hundred, near the bank of the Stour, between Colchester and Ipswich. East Bergholt has, from the number of good houses in it, an appearance superior to that of most villages. The church is of perpendicular architecture, and has some curious portions. Stratford is pleasantly situated, and has a handsome church. At Freston, on the bank of the Orwell, in the same hundred, is a quadrangular stone tower, about ten feet by twelve in area, and six stories high, with a polygonal turret at each angle. Its date and purpose are not ascertained. The population of East Bergholt in 1831 was 1360, of Stratford 630, and of Freston 183. Wickham-Market (population in 1831, 1202), in Wilford hundred, between Woodbridge and Saxmundham, is on a hill commanding an extensive prospect. South-Town and Gorleston, in Lothingland hundred, are suburbs of Yarmouth, and are included in its parliamentary boundaries. [YARMOUTH.]

Divisions for Ecclesiastical and Legal Purposes.—Suffolk is partly in the diocese of Norwich: it was formerly wholly included in it; but by the late alterations in the territorial arrangements of the church, the greater part of the archdeaconry of Sudbury, and part of the archdeaconry of Suffolk, have been transferred to the diocese of Ely. The eastern part is in the former diocese, the western part in the latter. The present ecclesiastical division of the county is as follows:—

1. Diocese of Norwich.

Archdeaconry of Suffolk.

Rural Deaneries.	Rect.	Vic.	Perp. Cur.	Chapelries, &c.	Total Cures.
Bosmere	19	4	4	3	30
Carlesford	9	2	6	.	17

	126	18	19	11	174
Total of the county .	324	98	74	26	522

By the union of cures the number of benefices is considerably reduced. Peculiars are not enumerated above. Chapels-of-ease are included in the fourth column. The above enumeration is from Cox's 'Clergy List' for 1842.

The peculiars are, Hadleigh and Monks-Eleigh rectories, and Moulton rectory and vicarage, belonging to Canterbury, and Freckenham rectory and vicarage, belonging to Rochester.

The county is included in the Norfolk circuit. The assizes are held in the spring at Bury St. Edmunds, and in the summer at Ipswich. The judges proceed to these places from Cambridge. Quarter-sessions for their respective divisions are held at Bury, Ipswich, Beccles, and Woodbridge. There are county gaols and houses of correction at Bury and Ipswich: county houses of correction at Woodbridge and Beccles; and borough prisons at Ipswich, Bury, Eye, Sudbury, Aldeburgh, Southwold, and Orford. The county gaol and house of correction at Ipswich was built A.D. 1790, on what was then considered the best plan; but there are several defects in the arrangement, and some additions which have been made are ill adapted to the original plan. The county gaol and house of correction at Bury are in an airy situation, just out of the town, well drained and well ventilated. The house of correction for females is a short distance from the gaol. The general management both of the county gaol and house of correction, and of the house of correction for females, is satisfactory. The houses of correction at Woodbridge and Beccles are ill arranged, and inadequate to that purpose. Of the borough prisons, some are inadequate and inconvenient: those at Orford and Aldeburgh are seldom used; and for the borough of Bury, prisoners are commonly sent to the county prison.

Suffolk is divided into the 'Geldable' portion, in which issues and forfeitures are paid to the king, and the 'Franchises,' in which they go to the lords of the liberties. The Geldable part comprehends the hundreds of Blything, Bosmere and Claydon, Hartismere, Hoxne, Lothingland and Mutford (two half hundreds), Samford, Stow and Wangford. The sessions held at Ipswich and Beccles are for this portion. The franchises or liberties are those of—1. St. Ethelred, including the hundreds of Carlford, Colneis, Loes, Plomesgate, Thredling, and Wilford; 2. St. Edmund, including the hundreds of Babergh, Blackbourn, Cosford, Lackford (including the half-hundred of Exning or Ixning, which is the part of the county nearly surrounded by Cambridgeshire), Risbridge, Thedwestry, and Thingoe; and 3. the Duke of Norfolk, including certain of his manors, for which he returns all writs, and receives all fines and amercements: he has also the right of appointing a coroner. The sessions for the two liberties of St. Ethelred and St. Edmund are held at Woodbridge and Bury respectively. The liberty of St. Edmund returns a grand jury at the assizes distinct from that returned by the rest of the county.

The counties of Norfolk and Suffolk were under one sheriff until the year 1576.

Before the Reform Act Suffolk returned sixteen members to Parliament: two for the county; and two each for the boroughs of Ipswich, Bury, Sudbury, Eye, Orford, Aldeburgh, and Dunwich. Ipswich and Sudbury were open boroughs, but very corrupt; Eye had about 200 voters; none of the others had more than 40 voters. By the Reform Act, the county was formed into two divisions, the Eastern and Western, each returning two members; Dunwich, Orford, and Aldeburgh were entirely disfranchised, and Eye was reduced to one member. Eleven members are therefore now returned from Suffolk, being five less than before the Reform Act.

The Eastern division of the county comprehends the hundreds of Blything, Bosmere and Claydon, Carlford, Colneis, Hoxne, Loes, Lothingland, Mutford, Plomesgate, Samford, Thredling, Wangford, and Wilford. The court of election is held at Ipswich; and the polling-places are Ipswich, Woodbridge, Needham-market, Framlingham, Saxmundham, Beccles, and Halesworth. The Western division comprehends the hundreds of Babergh, Blackbourn, Cosford, Hartismere, Lackford, Risbridge, Stow, Thedwestry, and Thingoe. The court of election is held at Bury; and the polling-stations are Bury, Wickham Brook, Lavenham, Stow-market, Botesdale, Mildenhall, and Hadleigh. A slight addition was made to Sudbury, and a considerable one to Eye.

The constituency is as follows:—

	[illegible]ders on the Register 1835 6.	18[illegible] 0.
East Suffolk . . .	6147	6104
West Suffolk. . . .	1952	5091
Ipswich	1418	1619
Bury	654	704
Sudbury	578	594
Eye	278	332

History and Antiquities.—Suffolk appears to have been comprehended with Norfolk in the territories of the Simeni (Σιμενοι) of Ptolemy, called by others the Iceni; or, if we follow Richard of Cirencester, it was in the territory of the Cenomanni, one of the divisions of the great Icenian nation. It was included in the Roman province of Flavia Cæsariensis. There were several British or Roman towns in this county, as the Sitomagus, Cambretonium, and Ad Ansam of Antoninus, and probably the Villa Faustini and Iciani of the same writer; and the Garannonum of the Notitia Imperii. The river Waveney and its valley appear, in the British and Roman periods, to have been one of the branches of that great æstuary which penetrated so deeply inland on this side of the island, as described elsewhere. [Norfolk, vol. xvi., p. 259.] It is there noticed that the æstuary penetrated at least as far as Bungay: it probably extended higher up, for we have seen that traces of antient navigation have been noticed as far up as Eye, which must have stood either upon a branch of this æstuary, or on some navigable river running into it.

The exact locality of the above-mentioned towns has been the subject of much difference of opinion. It will be well first to notice the direction in which Roman or other antient roads have been traced. A road from Londinium (London) and Camulodunum (Colchester) entered the county at Stratford, between Colchester and Ipswich, and leaving Ipswich on the right, ran in a northward direction to the Ipswich and Norwich road near Needham-market, and then coincided with the present line of that road till it quits the county to enter Norfolk at Scole inn.

Another line, 'the Peddar-way,' or 'Ieddar-way,' entering the county from Norfolk, across the Little Ouse near Rushford, runs southward to the neighbourhood of Ixworth, where Roman remains have been discovered. We believe this road has not been traced beyond Ixworth, or indeed scarcely so far; but the direction of existing lanes and roads, and the names of places, lead us to conjecture that it ran by Norton-Street, Woolpit, Fen-Street, and Low-Street to the neighbourhood of Bildeston, and possibly joined the road already described at the passage of the Stour at Stratford. 'The Ickneld-way,' or 'Icknield-Street,' crossed the county in a south-west direction from the Little Ouse to the neighbourhood of Newmarket. Another line, nearly parallel to this, appears to have run from the source of the Waveney and

* The rural deanery of Fordham is partly in Cambridgeshire, but the statement given above includes only that part which is in Suffolk.

Little Ouse (perhaps then the narrowest part of the æstuary, which, according to some traditions, insulated Norfolk) by Ixworth to the neighbourhood of Bury. Both these roads must have crossed the line of the Peddar-way, the latter near Ixworth, the former a few miles north of it. Besides these, there was in the eastern part of the county a road which entered the county across the æstuary of the Waveney at Bungay, and ran by Halesworth to Dunwich: it is known as Stone-Street; and a road crossed the south-western corner of the county by Haverhill, part of a line from Camalodunum (Colchester) to Camboritum (Cambridge). These are, we believe, all the known roads; but the remarkable peculiarities in the direction of existing roads and lanes convince us that a Roman road entered the county across the æstuary, now the valley of the Waveney, near Harleston in Norfolk, and ran to Peasenhall, in a direction which if continued would meet the coast at Aldeburgh. We think it probable too that a line of road branching from this at Peasenhall, or perhaps crossing it, in which case it may have come from near Southwold and Blythburgh, or else from Dunwich, ran into the line of road first described by Stone-Street, in the neighbourhood of Needham-Market.

Ad Ansam may be fixed at Stratford. The distance from Colchester (Camalodunum) coincides with that given by Antoninus, and the name Strat-ford, indicative of its position on the line of a Roman road or 'street,' convinces us that this position is correctly fixed. The distance given by Antoninus of the positions between Ad Ansam and Venta Icenorum (Caister, near Norwich) prevent our following the direct line of road; and the stations Cambretonium and Sitomagus, which occur in the interval, must be considered as doubtful. The proposal to fix them respectively at Grundisburgh, or rather Burgh, near Ipswich, where there is an antient encampment, and at Dunwich, is perhaps the best supported by a general though not exact accordance with the Antonine distances, and with the recognised pre-eminence of Dunwich in early Saxon times. It may be added that king Alfred calls Dunwich 'Dommoc-ceaster,' furnishing thus another indication of its Roman origin. The proposal to fix Sitomagus at Stowmarket, or Woolpit, we hold to be inadmissible. Blythburgh, though it has a better claim than either of these places, is not, we think, so well suited as Dunwich. Camden's opinion that Cambretonium was at Brettenham, is not objectionable in itself, but it renders it difficult to fix the position of Sitomagus. As for Iciani and Villa Faustini, we can only conjecture that the first was at Ixworth, where are some Roman remains, and the second on the Roman road at Yaxley, near Eye. Burgh castle, one of the most remarkable Roman remains in England, is described elsewhere. [BURGH CASTLE, vol. vi., p. 26.] It is generally supposed to have been the Gariannonum of the Notitia, but this may be doubted. [NORFOLK, vol. xvi., p. 268.]

Roman antiquities have been found at Blythburgh, on Bungay common, at Bury, at Dunwich, at Eye, at Haughley, near Stowmarket, where a Norman castle was erected on the site of a Roman camp, at Icklingham, near Mildenhall, at Ickworth, near Bury, at Ixning or Exning, near Newmarket, at Ixworth, at Pakenham near Ixworth, where a tessellated pavement was dug up, at Stow Langtoft in the same neighbourhood, where are the remains of a camp, at Felixtow near the mouth of the Deben, and at Wenham near Stratford.

In the Anglo-Saxon period Suffolk passed through similar changes to Norfolk. [NORFOLK.] It was probably settled by a body of Angles independent of those who occupied Norfolk. The names of South Folk and North Folk describe the relative position of these two bodies. Suffolk was probably, from its proximity to the other Anglo-Saxon states, the more important division of the two, and the scene of several events. The battle in which Annas or Anna, king of East Anglia, and his son Firminius, fell fighting against Penda, king of Mercia (A.D. 654), is supposed to have occurred at Bull camp or Bulchamp, near Blythburgh. Annas is said to have been buried at Blythburgh. St. Edmund, king of East Anglia, contemporary of Ethelred I., brother and predecessor of Alfred the Great, was taken by the Danes (A.D. 870), and cruelly murdered at Hagilsdun, now Hoxne (on the bank of the Waveney, near Scole), and was first buried there; but his body was afterwards removed to Bury, which has obtained from him its distinctive title of Bury St. Edmunds. In the Danish wars in the reign of Ethelred II., Ipswich was twice plundered by the Danes, once in A.D. 991, and again two years afterwards, A.D. 993. Again, in A.D. 1010, they occupied the town, extended their ravages inland, and gained a victory over the East Anglians, who, under their general Ulfcytel or Ulfkyttle, made head against them. The scene of this battle is not stated. In the closing period of the Anglo-Saxon dynasty, Suffolk was a separate earldom, under Gurth, the brother of Harold II. Gurth, as well as Harold, fell at Hastings.

In the civil war of Stephen and Henry of Anjou, afterwards Henry II., Ipswich, which was held by Hugh Bigod for Henry, was taken by Stephen (A.D. 1153). In the war of Henry the younger and his brothers against their father, Henry II., a body of Flemings under the Earl of Leicester, a partisan of the young prince, landed in Suffolk, at Walton, south-east of Ipswich, and were joined by Hugh Bigod, one of the most powerful noblemen of these parts. After vainly besieging Walton Castle, they advanced inland, and at Fornham St. Genoveve, on the bank of the Lark, between Bury and Mildenhall, were met and routed, with the loss of above ten thousand Flemings, by the king's army under Richard de Lacy and Humphrey de Bohun, constable of England. The Earl of Leicester and his wife were taken prisoners (A.D. 1173). Bigod, who had still a considerable force, made his peace with the government. In the civil war of John, the county was reduced to subjection (A.D. 1216) by William Fitzpiers, Robert Fitzwalter, and William de Huntingfield, dispatched for the purpose by Prince Louis of France, whom the barons had invited over to oppose John. In the insurrection of the populace in the time of Richard II. (A.D. 1382), those of Suffolk took arms, and murdered, at Bury, Sir John Cavendish, chief justice of England, and some of the monks of the abbey. The Essex insurgents appear to have been driven into this county after their first defeat at Billericay, and suffered a second defeat at Sudbury. In the rebellion of Lambert Simnel, Henry VII. raised an army, which he placed under the command of the Earl of Oxford to oppose a descent which he was apprehensive might be made in this county by a force from Flanders. In the disturbances caused by the attempt of Henry VIII. and his minister Wolsey to raise money by a royal decree (A.D. 1525), the people of Suffolk rose in rebellion, but the dukes of Norfolk and Suffolk prevailed on them to disperse. A part of the inhabitants of Suffolk took part in Kett's rebellion (A.D. 1549). On the death of Edward VI. and the proclamation of Lady Jane Gray as his successor, the Princess Mary, Edward's sister, who was at Kenninghall in Norfolk, removed to Framlingham Castle, where her partisans flocked to her. The Duke of Northumberland, Jane's father-in-law and general, advanced to Newmarket and from thence to Bury to oppose Mary, but retired next day to Cambridge; and the general feeling of the kingdom being in favour of Mary, she advanced from Framlingham to London, dismissing her Suffolk forces by the way.

In the middle ages Suffolk appears to have abounded with religious establishments. Tanner (*Notitia Monastica*) enumerates fifty abbeys, priories, hospitals, or colleges. Only three however of the greater monasteries, viz. those with 200*l.* clear yearly revenue, were in the county, viz. the abbeys of St. Edmunds Bury, Sibton, and Butley. The yearly revenue of Bury abbey (Benedictine) at the dissolution was 2336*l.* 16*s* gross, or 1659*l.* 13*s.* 11½*d.* clear; that of Butley Abbey (for canons of St. Augustin) was 318*l.* 17*s.* 2¼*d.*; and that of Sibton Abbey (Cistercian) was 250*l.* 15*s.* 7½*d.* The interesting remains of Bury Abbey are noticed elsewhere and the monastic ruins of Bungay. [BURY; BUNGAY.] Of Butley Abbey, between Woodbridge and Orford, the gate-house is the principal remain; it is incorporated in a modern mansion: there are some other remains of the abbey, but of less moment. Of Sibton Abbey, which is near Yoxford, on the road from Ipswich to Yarmouth, there are extensive remains. The monastic ruins of Eye, Dunwich, and Clare have been noticed in the former part of this article. There are some remains of Herringfleet Priory for canons of St. Augustin near Lowestoffe; of Leiston Premonstratensian abbey, near the coast, between Dunwich and Aldeburgh; and of Mendham Cluniac priory, on the Waveney, the latter partly converted into a farm-house. Of castellated remains the most remarkable are Framlingham, Orford, and Clare, already noticed; Bungay, noticed elsewhere [BUNGAY]; and Mettingham and Wingfield. Mettingham Castle is near Bungay; a considerable portion

of the gate-tower and fragments of the walls are standing. Wingfield is near Eye, the south or entrance front is still entire; the west side has been made into a farm-house. Of old mansion-houses, with which the county abounds, Flixton hall near Bungay; Giffard's hall, at Stoke by Neyland, on the Stour; Helmingham hall, near Debenham; Hengrave hall, north west of Bury; Kentwell hall and Melford hall, near Sudbury; and Parham hall near Framlingham, may be mentioned.

Few events connected with the great civil war of Charles I. occurred in this county. In the Dutch war of Charles II. two fierce engagements were fought on the coast. The first was fought 3rd June, 1665, off Lowestoffe. The English fleet consisted of one hundred and fourteen ships of war and a number of fireships and ketches, under the duke of York (afterwards James II.), having under him Prince Rupert, the earl of Sandwich, Penn, Lawson, Ayscue (or Ayscough), and other admirals; and the Dutch fleet, of above one hundred ships of war, besides small vessels, under admirals Opdam, Evertzen, Cortenaer, Cornelius van Tromp, and others. After a severe battle the Dutch were beaten with the loss of eighteen men of war taken and fourteen sunk or burned. The English lost one ship. The second battle was fought in Southwold Bay or Sole Bay, in 1672. A combined fleet, consisting, according to the lowest statement, of sixty-five English and thirty-five French men-of-war, under the duke of York as commander-in-chief, having under him the earl of Sandwich, Sir Joseph Jordan, Count d'Etrees, the French admiral, and others, was lying in the bay in careless security, in spite of the warning of Lord Sandwich, who had pointed out the danger of their being surprised, when a Dutch fleet of seventy-five, or, according to some accounts, of ninety-one men-of-war and a great number of smaller vessels, under De Ruyter, as commander-in-chief, with Evertzen, Van Ghent, Bankert, and others, came unexpectedly on them, on the 28th of May. A severe but indecisive action ensued. The English lost six ships of war, two burned, three sunk, and one taken. The earl of Sandwich was killed, and a number of officers and 2000 men killed and wounded. The French are charged with having hung back in consequence of secret instructions from their own government; however they lost two ships, and their rear-admiral was killed. The Dutch lost only three ships of war, but a great number of smaller vessels; their loss of men was probably great, as the States-General forbade the publication of it.

(*Ordnance Survey of England*; Conybeare and Phillips's *Outlines of the Geology of England and Wales*; Rickman's *Gothic Architecture*; *Beauties of England and Wales*; Gardner's *History of Dunwich*; Southey's *Naval History*, in Lardner's *Cabinet Cyclopædia*; Carte's *History of England*; *Parliamentary Papers*.)

Statistics.

Population and Occupations.—In 1831 Suffolk ranked the ninth among the agricultural counties, and 31,491 families out of 61,533 were 'chiefly employed in agriculture.' In manufacturing and non-agricultural occupations it stood the thirty-sixth in the list of English counties. In the manufacture of mixed silk and worsted stuffs 269 men were employed at Sudbury; 173 men were employed in drabbets and Tuscan plait at Haverhill, and 11 at Heddington; 42 in silk at Glimsford; a few at Lavenham; and 13 weavers at Hadleigh. At Brandon 60 men were employed in making gun-flints. At the same period, of males aged 20 and upwards, there were 4256 occupiers of land employing labourers; 1121 occupiers not employing labourers, and 33,040 were agricultural labourers, the latter being 46 per cent. of the total male population of the above age. The remainder of the male population aged 20 and upwards was thus distributed:—employed in manufactures, 676; in retail trades and handicrafts, 18,167; capitalists, bankers, and members of the professions, 2228; non-agricultural labourers, 5336; domestic servants, 1342; other males aged 20 and upwards, 4940. The number of male servants under 20 was 690; and there were 11,483 female servants.

The population of the county at the following periods was as under:—

	Males.	Females.	Total.	Increase per Cent
1801	101,091	109,340	210,431	
1811	111,988	122,223	234,211	11·3
1821	132,410	138,132	270,542	15·5
1831	145,769	150,548	296,317	9·5
1841	154,107	161,022	315,129	6·3

The population increased 104,698 from 1801 to 1841, being 49 per cent.; the increase for England during the same period being 79·9 per cent. The details of the census of 1841 are not yet fully published, but the number of inhabited houses was 64,081; uninhabited 2317; and 577 were building.

The population, &c. of each hundred and borough, according to the census of 1831, was as follows:—

Hundreds, Boroughs, &c.	Houses.				Occupations.			Persons.			
	Inhabited.	Families.	Building.	Uninhabited.	Families chiefly employed in agriculture.	Families chiefly employed in trade, manufactures, and handicraft.	All other Families not comprised in the two preceding classes.	Males.	Females.	Total of persons.	Males twenty years of age.

In each of the following years ending 25th March, the expenditure was as under:—

1835.	1836.	1837.	1838.	1839.	1840.
£224,904	£187,896	£136,870	£130,683	£145,871	£141,536

The expenditure in the last of the above years would average about 11*s.* 3½*d.* for each inhabitant. The total expenditure for the year ending 25th March, 1834, was 245,509*l.* The saving effected between that year and 1840 amounted to 123,175*l.*, or 45 per cent.; namely, under the head of relief and maintenance, 103,973*l.*, or 42 per cent.; in suits of law, &c., 6590*l.*, or 85 per cent.; and in miscellaneous expenses, 12,612*l.*, or 64 per cent. The number of poor-law unions is 16, comprising 507 parishes and a population of 281,320 according to the census of 1831: there are 2 parishes with a population of 11,436, which are not in any union. The number of paupers relieved during the quarter ending Lady-day, 1840, was 32,180 (4306 in-door, and 27,874 out-door), being 11 per cent. of the population, the proportion for England being 8·6 per cent. The illegitimate births in 1830 were 408, or 1 in 21; in England 1 in 20. The numbers affiliated in 1834-5 were 311; and in 1835-6, 209. Bastard children chargeable on the poors'-rate in 1835-6, 1558, or 1 in 190 of the whole population—in England 1 in 215. Lunatics and idiots chargeable on the same fund in 1836, 345, or 1 in 859;—in England 1 in 1033. Proportion per cent. of persons married under 21 years of age in 1840, 12·9;—in England and Wales, 9·6 for the two sexes.

The annual value of real property assessed to the property-tax in 1815, was 1,127,404*l.* The sum raised for poor-rate, county-rate, and other local purposes, for the year ending 25th March, 1833, was 300,016*l.*, levied

On land . . .	£247,543
Dwelling-houses . .	45,522
Mills, factories, &c. . .	5,868
Manorial profits, navigation, &c.	1,082
Total	£300,016

The amount expended was—

For the relief of the poor . .	£259,098
In suits of law, removal of paupers, &c. .	7,059
For other purposes . . .	33,900
Total money expended	£300,058

The county expenditure in 1834, exclusive of that for the relief of the poor, was 15,878*l.* disbursed as follows:—

Bridges, building, repairs, &c. .	£746
Gaols, houses of correction, and maintaining prisoners . . .	5782
Shire-hall and courts of justice, building, repairs, &c. . . .	294
Lunatic asylums . . .	903
Prosecutions . . .	2,509
Clerk of the peace . . .	854
Conveyance of prisoners before trial	1,225
Conveyance of transports . .	319
Vagrants, apprehending and conveying	23
Constables, high and special . .	666
Coroner	273
Payment of principal and interest of debt	1,000
Miscellaneous . . .	1,280
Total	£15,878

The county-rate levied at different periods, and the principal disbursements, are shown in the following table:—

	1805.	1811.	1821.	1831.	1838.
	£	£	£	£	£
Income .	25,557	12,923	17,138	12,457	17,765
Expenditure:—					
Bridges .	1,507	364	1,143	676	1,128
Gaols .	4,738	1,369	7,410	2,973	346
Prisoners' maintenance	779	980	1,185	4,534	3,959
Prosecutions	396	649	1,301	2,130	3,567
Constables and vagrants .	344	437	1,030	587	1,081

In 1839 the length of streets and highways, and the expenditure thereon, were as under:—

	Miles.
Streets and roads repaired under local acts	252
Turnpike roads	221
All other highways	2,859
	3,333

Amount of rates levied . . .		£25,480
Expended in repairs of highways	£25,371	
Law and other expenses .	466	
Total expenditure		25,838

The number of turnpike trusts in 1839 was 14; income from tolls, 9,940*l.*; from parish compositions, in lieu of statute duty, 57*l.*; and the total income was 10,337*l.*, the total expenditure for the same year being 10,583*l.* The assets, including arrears of income, amounted to 2,117*l.*; the debts to 34,288*l.* In 1836 the debt was equal to 2·8 years of the annual income;—the proportion for England being 4½ years; the proportion of unpaid interest to the total debt was 16 per cent., the average for England being 12 per cent.

In 1839 the church-rates amounted to 11,988*l.*; and 3,194*l.* applicable to the same objects was derived from other sources. In 1832 the sum derived from 'other sources' included 3,979*l.* from estates and rent charges. The sum expended for the purposes of the Establishment amounted to 14,443*l.* in 1839, out of which 7,164*l.* were expended on repairs of churches.

Crime.—Number of persons charged with criminal offences in the septennial periods ending 1819, 1826, 1833, and 1840:—

	1813-19.	1820-26.	1827-33.	1834-40
Total . .	1,300	1,913	2,631	3,170
Annual average	185	277	375	495

The numbers committed, convicted, and acquitted in each year from 1834 to 1839 were as under:—

	1834.	1835.	1836.	1837.	1838.	1839.	1840.
Committed	484	450	528	493	505	527	484
Acquitted	138	134	157	159	163	152	135
Convicted	346	316	371	334	342	375	349

In 1834 the proportion of persons committed, to the total population of the county, was 1 in 612; and in 1840, allowing for the increase of population, 1 in about 619.

Of 484 criminal offenders tried at the assizes and sessions in 1840, there were 24 charged with offences against the person; 40 with offences against property committed with violence; 401 (including 327 cases of simple larceny) with offences against property committed without violence; 3 with malicious offences against property; 3 for forgery and uttering base coin; and 13 for various misdemeanors. About eighty-two per cent. of the offences were those against property committed without violence; and about sixty-seven per cent. were cases of petty larceny. Sentence of death was recorded in 1 case, which was commuted into transportation for life. Of 349 offenders convicted, including the one above-mentioned, 5 were transported for life; 1 for above 15 years; 19 for periods varying from 10 to 15 years; 21 from 7 to 10 years; 36 for 7 years—making in all 83 offenders transported; 1 was imprisoned for above 2 years; 18 for a term exceeding 12 months; 51 for above 6 months; and 193 for 6 months and under; and 3 were whipped, fined, or discharged on sureties. The acquittals were 135 in number; in 15 cases there was no prosecution; in 38 no bill was found; and 82 persons were found not guilty on trial. Of the total number committed, 400 were males and 84 females: 177 males and 24 females could neither read nor write; 173 males and 53 females could read, or read and write imperfectly; 37 males and 4 females could read and write well; and the state of instruction of 13 males and 3 females was not ascertained. On an average of several years the proportion of uninstructed criminals in this county was 86·6 per cent.; those instructed 13·4 per cent.;—the average of the former for England and Wales being 89·3 per cent.

Savings Banks.—There are 13 of these institutions; and the number of depositors and amount of deposits on the

20th of November in each of the following years was as under:—

	1835.	1836.	1837.	1838.	1839.	1840.
No. of depositors	5,751	6,675	7,208	7,880	8,503	9,332
Am. of deposits	£178,591	£203,794	£217,915	£236,730	£255,789	£280,913

The distribution of the sums invested in 1830, 1834, and 1839, on the 20th of November in each year, was as under:—

	1830		1834.		1839.	
	Depositors.	Deposits.	Depositors.	Deposits.	Depositors.	Deposits.
Not exceeding £20	2,763	£20,795	3,115	£23,321	4,616	£33,427
,, 50	1,489	46,098	1,694	51,815	2,345	72,574
,, 100	722	48,871	789	54,868	933	65,466
,, 150	233	27,392	256	30,841	366	44,649
,, 200	103	17,920	121	20,412	192	32,268
Above . . 200	51	12,439	29	7,354	31	7,405
	5,371	173,541	6,004	187,611	8,503	255,789

The deposits of 200 friendly societies, not reckoned above, amounted, in 1840, to 22,158*l.*; and 8670*l.* were invested by 200 charitable institutions.

The state of the elective franchise in 1839-40 is shown in the following table:—

	E. div.	W. div.	Total.
Freeholders of every class . .	3,708	3,056	6,764
Copyholders and customary tenants	742	570	1,312
Leaseholders for life or for a term	40	22	62
50*l.* tenants at will	1,683	1,283	2,966
Trustees and mortgagees .	14	13	27
Qualified by offices . . .	134	131	265
Joint and duplicate qualifications	83	96	179
	6,404	5,091	11,495

Education.—Summary of the Returns made to Parliament in 1833:—

	Schools.	Scholars.	Total.
Infant schools	117		
Number of children at such schools; ages from 2 to 7 years:—			
Males . .		595	
Females . .		639	
Sex not specified .		879	
			2,113
Daily schools	961		
Number of children at such schools; ages from 4 to 14 years:—			
Males . .		11,733	
Females . .		10,317	
Sex not specified .		4,479	
			26,529
Schools . . .	1,078		
Total of children under daily instruction			28,642
Sunday schools	488		
Number of children at such schools; ages from 4 to 15 years:—			
Males . .		12,477	
Females . .		13,015	
Sex not specified .		4,738	
			30,234

The number of children in Suffolk, in 1833, between the ages of 2 and 15, may be computed at about 77,000, and between 4 and 14, at about 66,000. Eighty Sunday-schools, attended by 3130 children, were returned from places where no other schools existed; but in all other places in the county the children had also the opportunity, and many of them were in the habit, of attending daily schools as well; but to what extent duplicate returns were caused by this circumstance cannot be ascertained. Fifty-seven schools, attended by 3910 children, were both Sunday and daily schools, and thus far only can duplicate returns be discovered. Taking the numbers returned under daily instruction (28,642), and those attending Sunday-schools (30,230), the total number of children is 58,872, which falls short by some thousands of the total number of children between the ages of 2 and 15. The number of boarding-schools was 58.

Maintenance of Schools.

Description of Schools.	By endowment.		By subscription		By payments from scholars.		Subscrip. and payment from scholars.	
	Schls.	Scholars.	Schls.	Scholars.	Schls.	Scholars.	Schls.	Scholars.

Total...	115	3968	547	31,228	789	17,407	117	6269

According to the Reports of the Charity Commissioners, there are annual funds amounting to 3991*l.* applicable to the purposes of education; the income of endowed schools is 2972*l.*, and a sum of 1018*l.* is for educational purposes in schools not endowed.

The Schools established by Dissenters, included in the above table, are—

		Scholars.
Daily-schools . . .	15, containing	390
Sunday-schools . . .	105, .	9,199

The schools established since 1818 are—

Infant and other daily schools .	508, containing	13,763
Sunday-schools . .	231, .	16,281

Lending libraries were attached to 41 schools in 1833.

SUFFRAGAN. [BISHOP.]

SUGAR (French, *Sucre*; German, *Zucker*; Italian, *Zucchero*; Russian, *Sachar*; Spanish, *Azucar*; Arabic, *Sukhir*; Malay, *Soola*; Sanscrit, *Sarkara**). The sugar of commerce is a sweet crystallized substance, most commonly prepared from the expressed juice of the sugar-cane, of which there are several species [SACCHARUM, vol. xx., p. 299]; but sometimes from beet-root [BEET, vol. iv., p. 160], from the sap of one or more species of maple [ACER, vol. i., p. 79], and from other vegetable productions. Saccharine matter is indeed one of the most common of vegetable secretions [SECRETIONS, VEGETABLE, vol. xxi., p. 178]; but it is only from the above-mentioned substances that sugar has been extracted to any great extent as an article of commerce, and of these the sugar-cane is by far the most extensively used.

The chemical properties of various kinds of sugar are detailed in the succeeding articles (pp. 234, 235), which also notice most of the sources whence saccharine matter may be obtained. The latter part of the subject is more fully treated of in two papers read before the Society of Arts, in February, 1830, by their late secretary, Arthur Aikin, Esq., and published in the fifty-first volume of their 'Transactions.' A brief enumeration of the principal saccharine substances known to chemists, chiefly condensed from these papers, may assist the reader in taking a connected view of the subject.

Mr. Aikin commences his account of the substances which communicate the sensation of sweetness to the organs of taste, by alluding to the singular fact that the sensation may, under particular circumstances, be produced not merely by the contact of a sweet substance with the nervous papillæ of the tongue and palate, but also by the contact of a perfectly neutral or insipid substance, after the nerves have been over-excited by that sensation which is opposite to sweet. This opposite, he observes, is *bitter*; or, more properly speaking, *acerb*. This circumstance, which is analogous to a well-known optical phenomenon (alluded to in the account of ocular spectra, in the article SIGHT (vol. xxi., p. 506), is supposed to account for the reported sweetness of the waters of the Nile and some other rivers in the East; since natural pure water, which we should merely designate *fresh*, is, 'not metaphorically, but actually and literally, sweet and delicious as milk,' to the palates of travellers who have been compelled to drink of the bitter springs found in the sandy deserts of Syria and Arabia, and in those which insulate the valley of the Nile. The sensation of sweetness is produced not only by many vegetable and animal substances, but also by some of purely chemical character. Of the latter Aikin mentions the soluble salts of lead (one of which, the acetate, was formerly called *sugar of lead*); the hydrosulphates of silver and copper; and an earth which exists in the emerald, and which has been called glucine from its property of forming sweet salts with acids. [GLUCINIUM, vol. xi., p. 277.]

Of animal substances Aikin observes that the muscular parts of all quadrupeds, birds, and fishes, if boiled or roasted soon after death, have a decided though slight degree of sweetness; which sweetness disappears on the commencement of the spontaneous change which ends in putrefactive decomposition. That the sweet principle does not reside in the muscular fibre is presumed from the circumstance that it may be extracted from flesh by boiling water, in which

* The above list of synonymes is taken from M'Culloch's 'Dictionary of Commerce.' Dr. Benjamin Moseley (*Treatise on Sugar*, second edition, p. 4) gives a rather longer list, varying from this in a few minor points of orthography, and containing the following terms under which sugar is referred to by Greek and Roman writers:—*Μέλι καλάμινον*, Theophrastus; *Σάκχαρον*, Dioscorides; *Saccaron*, Pliny; *Σάκχαρι*, and *Μέλι καλάμινον*, Arrian; *Σάκχαρ*, Galen; and Ἅλς Ἰνδικός, P. Ægineta, from Archigenes.

muscular fibre is insoluble; but as Aikin was not aware of any attempts to obtain the sweet matter in a separate state, he could not tell whether it agrees in essential character with any of the other sweets obtainable from the products of animal and vegetable organization. Glycerin is a sweet substance obtainable from most of the fats or expressed oils, whether animal or vegetable, by the process of saponification. [SOAP, vol. xxii., p. 169.] In its purest state, glycerin is in the form of a sweet syrup, which is not capable of crystallizing or undergoing the vinous fermentation. The sweet taste of new milk is occasioned by a saccharine substance called sugar of milk, the proportion of which, in the milk of various animals, is shown in vol. xv., p. 218 [MILK], while its chemical composition is given in p. 235 of this volume. This substance has been, and we presume still is, made in considerable quantities in some parts of Switzerland, for medicinal purposes. It is, according to Aikin, made from the whey left after making cheese. The whey is first heated to separate the butter from it, and is then boiled down to the consistence of syrup, which is poured into earthen pots, and exposed to the sun until it is nearly solid. The mass is then put into water, and heated till the sugar is dissolved, and the insoluble impurities are separated by pouring the hot liquor through a linen filter. It is then clarified with white of egg, and is again evaporated. It deposits, on cooling, a whitish crystalline mass, which differs little from vegetable sugar, but is less soluble in water, and will not undergo the vinous fermentation, although it be mixed with yest. Beckmann, who notices the history of the invention of this substance in his 'History of Inventions' (vol. iv., p. 599, English edit. of 1814), describes the mode of preparing it from new milk; but he observes that the sugar so made is fatter, and more liable to spoil, than that given by milk from which the butyraceous and caseous parts have been carefully separated. The only other sugar of animal origin, mentioned by Mr. Aikin, is that found in the urine of persons suffering under the disease called *diabetes mellitus*. [DIABETES, vol. viii., p. 479.]

Honey-dew, or aphis-sugar, and the honey of the bee, are intermediate between animal and vegetable sugars; because, though derived from vegetable juices, they are modified by digestion in the stomachs of insects. Honey-sugar is described in p. 235 of this volume; and in the article on the properties of sugar, in the same page, is a notice of the formation of sugar from the starch contained in many vegetable productions. Among vegetables which contain sugar ready formed (though not in a crystallized or separate state), there are several trees from the sap of which it may be obtained in sufficient quantity for human use. Two of these—the sycamore and the birch—are natives of Britain; but the sugar which they yield is not sufficient to repay the expense of manufacture. The sugar-maple, which abounds in some parts of North America, yields sugar in such abundance as to be of considerable importance. Many trees of the palm family afford a sweet sap, which may be boiled down to a tolerably solid viscid sugar. [BORASSUS, vol. v., p. 173.] Palm-sugar is called *dibs;* and Mr. Aikin thinks that perhaps it is alluded to by Pliny under the name *dablan* (xiii. 7). For notices of manna-sugar, see MANNA, vol. xiv., p. 386, and pp. 235 and 236 of this volume.

Saccharine matter exists in many ripe fruits in great abundance, as is evident not only from their sweet taste, but also from the circumstance that it exudes from some, as the fig and the grape, in the process of drying. From the former of these, as well as from the date and the plantain, it appears that sugar has never been made, perhaps owing to the difficulty of extracting granulated sugar from a fruit containing so much mucilage. Attempts have been made to extract solid sugar from grapes, but without much success. M. Proust, a chemist in the service of the king of Spain, tried to accomplish this object, with the hope of preventing the annual waste of many thousand tons of grapes; but while he obtained a solid sugar of coarse quality, it was at too great an expense to bear competition with common sugar. Political troubles put an end to this experiment; but the manufacture of sugar from grapes was again tried in consequence of the loss of the French sugar colonies, under the encouragement of the French government. Great difficulty was experienced from the strong tendency of the juice, when expressed from the grapes, to ferment; from its liability to contract an empyreumatic flavour while boiling down; and from the difficulty of separating the tartar which all grape-juice contains. The two former difficulties were much lessened by the judicious application of sulphurous acid, but the last was not overcome; and at length the attempt to separate the sugar in a crystallized form was abandoned; and the juice, reduced to a thick syrup, was brought into extensive use as a substitute for sugar, until the return of peace rendered its use no longer necessary. Aikin states that white grapes were preferred for the purpose. The first process in the manufacture was the addition of sulphurous acid to the juice, either by stirring into the cold liquor sulphite of lime, in the proportion of 1 to 400 or 500 of the liquor; or by filling a tub with sulphurous acid gas, and then pouring the juice into it through a colander, so that it might be divided into a great number of streams, to facilitate the absorption of the gas. The liquor then remained quiet for a day or two, in which time much insoluble matter was deposited. The clear liquor, being drawn off, was then boiled; alone, if it had been mixed with sulphite of lime; or with the addition of some chalk, if sulphurous acid gas had been employed. After a partial evaporation, the syrup was clarified, either with blood, with white of egg, or with animal charcoal and white of egg, the latter being considered the best. The liquor, while boiling hot, was run through a filter, and subsequently boiled down to a thick syrup. When the sugar was required in a solid state, the syrup was boiled rather more than in the former case, and was kept in a cool place for a fortnight after boiling. At the end of this time it had the consistency of candied honey; and by subjecting it to pressure about one-third of its weight was obtained of soft sugar, of an agreeable flavour, but mealy, and apt to become moist in damp weather. It was also liable to curdle milk, and consequently unfit for many culinary purposes. The chemical composition of grape-sugar is given in pp. 234, 5. Aikin states that the *rob* of grapes, that is, the juice boiled down to the consistence of honey, has been long known in Syria and Egypt; and that Dr. Shaw, who, when in those countries, ascertained that two thousand quintals of it were annually exported to Egypt from the neighbourhood of Hebron alone, is inclined to attribute a very high antiquity to this preparation. He says further that Dr. Russell, in his 'History of Aleppo,' mentions it under the name of *dibbs* (being the same that is applied to date-sugar), and represents it as a common article of food at that place.

Several roots, particularly of the tuberous or fleshy kind, contain sufficient saccharine matter to be important, either for separating it in a pure state, or in the form of an extract of all the soluble ingredients of the root. Of all the latter class liquorice is one of the most important. See GLYCYRRHIZA GLABRA (vol. xi., p. 278), and *Liquorice Sugar*, in p. 235 of this volume. For the former purpose, attempts have been made upon several fleshy roots employed as food. Marggraf, a Prussian chemist, called public attention to the subject by a memoir printed in the 'Transactions' of the Academy of Berlin, for 1747. The roots he tried were the skirret (a variety of parsnep), the white beet, and the red beet. His experiments were resumed some years afterwards by M. Achard, at the desire of the Prussian government. Probably these and some other early experiments led, in some degree, to the subsequent introduction of the manufacture of beet-root sugar in France under M. Chaptal. [BEET, vol iv., p. 160.]

The above details show how many sources there are from which sugar might be obtained. None of them however, as far as experiment has shown hitherto, will bear comparison with the sugar-cane in point of cheapness; so that it is doubtful whether even beet-root sugar could enter into competition with that from the cane, unless aided by fiscal regulations.

Notices of Sugar and the Sugar-cane by antient writers.—It has been conjectured, although the opinion is not generally adopted, that the Hebrew word used in several places in the Old Testament, and rendered by our translators *calamus* in some places, and in others *sweet cane*, refers to the sugar-cane. Whatever the sweet cane alluded to may have been, it was apparently an article of merchandise in early times; and, as it is mentioned as coming from a far country, it was probably not a production of either Egypt or Judæa. (See *Exod.*, xxx. 23; *Sol. Song*, iv. 14: *Is*, xliii. 24; *Jer.*, vi. 20; *Ezek.*, xxvii. 19.) Dr. Moseley (*Treatise on Sugar*, second edit., pp. 127-136) has combated this conjecture at considerable length. He also opposes the idea of there being any connection between the term *shecar* or *shuker*, which is commonly rendered in the
